Inaugural Address

ON THE

MEDICAL NEEDS OF INDIA.

Delivered at the London School of Medicine for Women on Oct. 1st, 1913,

BY SURGEON-GENERAL SIR CHARLES PARDEY LUKIS, K.C.S.I., M.D. LOND., F.R.C.S. ENG.,

DIRECTOR-GENERAL, INDIAN MEDICAL SERVICE.

DR. GARRETT ANDERSON, LADIES, AND GENTLEMEN,—I have in the first place to express my sense of the honour done me by your council in asking me to deliver the inaugural address this afternoon, and to say how very pleased I am to be able to accept the kind invitation extended to me. The subject which I have selected is the Medical Needs of India, my reason for this choice being that in my opinion one of the most urgent needs of India at the present time is an adequate supply of suitable and fully-trained medical women.

The problems connected with the preservation of the public health in India are extremely complex, especially as regards the remedying of sanitary defects, the education of the people in personal and domestic hygiene, the saving of infant life, and the protection of women from the dangers incidental to childbirth.

SANITARY QUESTIONS: MALARIA, PLAGUE, AND TUBERCULOSIS.

The time at my disposal being limited I do not propose to-day to deal with the larger sanitary questions. Neither is it necessary that I should do so. Under present conditions such questions are outside the scope of the work of the medical woman in India. I must, however, say a few words on the subject of the education of the Indian public in personal and domestic hygiene, because it is the prejudices of the vast majority of the populace, their conservatism, and their suspicion of any innovation or change, which constitute such a formidable obstacle to rapid progress in medical or sanitary matters. In order to illustrate my point let us consider briefly some of the conditions influencing the spread in India of those three deadly diseases—malaria, plague, and tuberculosis. Malaria, as you know, is conveyed from man to man by certain species of anopheline mosquitoes. For a long time it was thought that all malaria arose from swamps, but recent observations have shown that this is not the case. Thus the researches of Liston and Bentley have proved that the severe epidemic of malaria from which Bombay city has suffered of recent years does not arise from the surrounding swamps, but is conveyed by a species of domestic mosquito which breeds in the wells attached to private houses. Similarly, much of the malaria which occurs in up-country stations is due to the breeding of mosquitoes in collections of stagnant water in and around habitations. It is obvious, therefore, that the attempts of Government to stamp out malaria are apt to be nullified if householders refuse to close down private wells, which are a danger to the community, or persist in allowing broken earthen pots, old kerosene oil tins, &c., to accumulate in their yards and thus furnish breeding grounds for mosquitoes.

Then again, as regards epidemic plague, the history of which as it occurs amongst human beings is as follows. Plague occurs amongst the rats in a house. So soon as the rats begin to die the remainder at once migrate from the infected spot, but they leave behind them their nests, and in these nests are a large number of rat-fleas which contain plague bacilli owing to their having sucked the blood of infected rats. Presently these fleas become hungry, and, finding no rats, they sally forth and bite human beings, thus infecting them with plague. The question of the prevention of plague is therefore chiefly one of domestic hygiene, and it is essential that the public should realise the danger of permitting collections of rubbish in and about their houses behind which rats can build their nests. They should be taught also not to throw about in the vicinity of their houses remnants of food which will attract rats, and, in fact, every precaution should be taken to prevent the rat from becoming a domestic animal. The rat is not a domestic animal in the houses of Europeans in India, but it is a domestic animal in the houses of a large number of Indians, and this I believe to be the explanation of the difference in the plague-incidence on the two races.

I now come to the subject of tuberculosis. Nowadays there is a great boom in tropical diseases, and it is right that there should be, but one ill effect of this is that it is apt to distract attention from diseases which, although not, strictly speaking, tropical in origin, nevertheless create enormous havoc in tropical countries. The chief of these is tuberculosis, the mortality from which in some of our larger native cities exceeds that of either Birmingham or Glasgow. Tuberculosis in India, however, differs from that disease in England in one striking particular—it is invariably of human and not of bovine origin. For this there are two explanations: the first is that Indian cattle are practically free from tuberculosis. When I made this statement at the recent Conference on Infant Mortality it was received with a certain amount of scepticism, but I am glad to learn from competent observers that similar conditions prevail both in Ceylon and in the Malay Peninsula. The second explanation is that Indians never drink unboiled milk—consequently milk may be regarded as a negligible factor in the spread of tuberculosis in India; and the disease is always conveyed by human agency as the result of defective ventilation, overcrowding, and indiscriminate spitting. The Government and the local authorities are doing all in their power in the matter of town planning and the provision of sufficient light and air in tenements, and by the prohibition of expectoration in public places, but their efforts will be of little or no avail until the Indian public learn the danger of sleeping in closed rooms and of permitting indiscriminate spitting within house limits.

THE TEACHING OF PERSONAL AND DOMESTIC HYGIENE.

Hitherto the teaching of personal and domestic hygiene in India has been very unsatisfactory. It has been regarded merely as a school lesson to be learnt by rote, and I doubt very much whether the scholars attach any importance to it or regulate their lives by its precepts. You may, for instance, hear a boy state in school: "I must eat clean food: I must drink pure water," and then as soon as school is over he will scamper off and eat sweetmeats from a fly-infested open stall in the bazaar, assuaging his thirst with a draught of water from the village tank, which is indiscriminately used for drinking purposes, for bathing, and for the washing of clothes.

Efforts are now being made both by Government and by the St. John Ambulance Association to render instruction in hygiene more practical by means of lantern demonstrations, popular lectures, and the distribution of illustrated leaflets, but even if these efforts are as successful as it is hoped they may be, they will not reach the root of the evil, for they will only instruct the men of the community. This is my reason and excuse for bringing the matter to your notice to-day. Ladies who have spent all their lives in England are apt to regard their Indian sisters as being very downtrodden and oppressed. This is a grave mistake. Out of doors the man is lord of creation, but once he is inside the house he is absolutely controlled by his wife and mother in all matters concerning domestic economy and the family life. Indeed, I know of no country where the woman is more absolutely the mistress of the house than she is in India, and I am convinced that we shall never make any real headway in promoting the knowledge of domestic and personal hygiene until we have convinced the women of India as to its necessity, and they have thrown their powerful influence into the scale. Here the medical man is powerless—the *purdah* bars the way, and it is to the medical woman that we must look for educational propaganda inside the zenana.

I have dealt with this subject at some length because I wish to lay stress upon the fact that the work of medical women in India should not be confined merely to the care of women and children. They may do admirable pioneer work by disseminating knowledge of the laws of health and the value of preventive measures, thus conferring an incalculable boon upon the populace as a whole, both by showing them how to prevent the spread of communicable disease, and by

(RECAP) 8950 .558 1913, v.2, pt.2 707410

teaching them how to increase the natural powers of resistance against pathogenic germs.

INFANT MORTALITY.

The subject of infant mortality in India has of recent years attracted considerable attention. That it is a subject imperatively demanding such attention cannot be denied. In 1911, 4,752,152 male children and 4,457,551 females were born in India, and in the same year the actual number of deaths of children under one year of age was 1,016,823 males and 873,677 females; that is to say, roughly speaking, about one-fifth of the children born died within the first year of their life. It is very difficult to arrive at the actual causes of this high rate of mortality. The figures at our disposal are often of doubtful accuracy, and the comparison of figures from different localities is most fallacious. A relatively high reported death-rate frequently means merely that the registration of vital statistics in this particular locality is carried out more satisfactorily than in some other place with a more enviable but totally undeserved reputation, and one of the greatest of our present necessities is an improvement in our methods of collecting vital statistics. In most of the large cities and towns of India the number of births and deaths reported probably approximates to the truth, but with regard to the causes of death even approximate accuracy is rarely attained. This is inevitable when the diagnosis of the cause of death is in the vast majority of instances made by persons with no medical training. Moreover, when death is due to infectious disease wilful concealment frequently occurs.

As the result of inquiries made in four large towns in India, Major Robertson, the Sanitary Commissioner with the Government of India, is of opinion that the causes of infant mortality, taken in the order of their importance, may be classified under four headings: (1) Malaria, operating both directly on the infant and indirectly through the mother; (2) diseases due to insanitary surroundings; (3) diseases due to ignorance on the part of the mother with regard to the feeding and care of the infant; (4) accidents of childbirth and diseases attendant thereon.

As regards the last two groups, I believe that early marriage is very largely responsible for the high rate of infant mortality in India, where marriage is almost universal and at the earliest practicable age; and there can be no doubt that much of this mortality is due to the ignorance and immaturity of the mothers. The instruction of these young mothers, therefore, in all matters connected with antenatal and postnatal hygiene is a point deserving of consideration by all medical women practising in India.

Another adverse factor vying in importance with that of early marriage in determining the excessive mortality is to be found in the primitive methods of midwifery almost universally in vogue. Not only do such methods lead directly to the death of the infant from tetanus and other infections, but they also indirectly increase the infant mortality by depriving the children of their natural nourishment, for it must be remembered that, owing to the unsatisfactory substitutes given as food to children deprived of their mothers' milk, the death of the mother, or even the drying up of her milk as the result of sepsis, in the majority of cases practically seals the fate of the child. I need not dilate upon the suffering and loss of life which result from these primitive methods of midwifery. As you probably are aware, in India the deaths in childbed are about three times as numerous as they are in England. The only remedy for this deplorable state of affairs is that medical women, by their precepts and practice, should create confidence in modern midwifery and devote themselves to the systematic instruction of the native midwives.

THE WOMEN'S MEDICAL SERVICE FOR INDIA.

I think I have said enough to bear out my opening statement that one of the most urgent needs of India at the present time is an adequate supply of suitable and fully trained medical women, and I now pass on to the consideration of the manner in which it is proposed to supply this need.

The work of supplying female medical aid to the women of India is chiefly performed by two voluntary agencies—that of the missionaries and what is generally known as the Lady Dufferin Association. Of late years the work of the latter association has been subjected to much criticism, and there can be no doubt that the conditions of service have not been such as are calculated to attract the right stamp of medical woman. Various complaints have been made, especially as regards subordination to men, liability to sudden dismissal, absence of incremental rates of pay or provision for retirement, or any definite rules as regards furlough and study leave. I do not propose to enter here into the controversy that has raged round this subject, but I shall merely state for your information the manner in which it is now proposed to redress the legitimate grievances and improve the position of medical women serving under the Dufferin Association.

In the first place, it may be as well to mention that the Government of India have decided definitely against the creation of a State service of medical women; they have, however, approved of a grant of £10,000 per annum for a service of medical women under the Central Committee of the Dufferin Association. This service will be called "The Women's Medical Service for India," and I have received the permission of the Central Committee to sketch out for you in outline the conditions of service which received final sanction at the meeting held in Simla early last month.

The service in the first instance will not exceed 25 first-class medical women, one-fifth of whom will constitute a leave reserve. Its members, subject to certain provisions, which I will mention later on, will be under the direction and control of the Central Committee of the Dufferin Association. I may mention here that there is already one medical woman serving on this committee, and that the question of adding a second is now under consideration. Recruitment for the service will be made in two ways: (*a*) *In India*, by a medical subcommittee of the Central Committee which shall include the Director-General of the Indian Medical Service, the Surgeon to His Excellency the Viceroy (who is also the honorary secretary to the Central Committee), and a first-class medical woman. (*b*) *In England*, by a subcommittee consisting of a medical man and two medical women conversant with Indian conditions, to be nominated by the Home Committee of the Dufferin Association. Such subcommittees will perform the duties of a Medical Board, examine candidates for physical fitness and give permission to return to duty after invaliding, and in India the subcommittee will have power to appoint temporary local boards in cases of emergency.

The central committee will decide what proportion of the members of this service shall be recruited in England and in India respectively. In the original constitution of the service duly qualified medical women who are already in the service of, or who have rendered approved service to, the Dufferin Association will have first claim to appointment, and thereafter special consideration will be paid to the claims of candidates who have qualified in local institutions and of those who are natives of India.

All newly appointed members of the service must be British subjects. They must be not less than 24 or more than 30 years of age at the time of recruitment, and they will, except under special circumstances, be retired on attaining the age of 48. They must possess a medical qualification registrable in the United Kingdom under the Medical Act or an Indian or colonial qualification higher than the L.M.S. and they must produce certificates of health and character. They will engage for general service anywhere in India or Burma, and they will then be appointed by the central committee to serve in different provinces. On first appointment they will serve a period of probation in one of the larger hospitals, extending in the case of those recruited in England to six months and in the case of those recruited in India to three months. At the end of such period of probation their appointment will be confirmed or terminated, as the case may be, by order of the central committee, and after confirmation service will be terminable at any time by three months' notice on either side.

Members of the service will receive a salary of Rs.350 per mensem during their period of probation, and thereafter a salary of Rs.400 from the first to the fourth year inclusive, Rs.450 from the fifth to the seventh year, Rs.500 from the eighth to the tenth year, and Rs.550 after the tenth year, but no member will be confirmed in the Rs.400 grade unless she passes her examination in the vernacular within one year of her appointment. In addition suitable quarters will be provided free of rent, or house rent will be given in lieu thereof. There will also be a provident fund as a provision for retirement. Members of the service will draw travelling

allowance at the usual rates, and they will be entitled, in addition to the usual privilege leave, to eight months' furlough after four years' service and to study-leave up to nine months. Whilst on furlough they will draw half-pay and two-thirds whilst on study-leave. They will be permitted to engage in private practice, provided that such private practice does not interfere with the performance of their official duties.

When members of the service are appointed to provinces they will forthwith become subordinate to the provincial committee which shall have powers of punishment, including suspension, but the power of removal from the service or dismissal for inefficiency, misconduct, or other valid cause, will be vested absolutely in the central committee. Any member of the service who has been recruited in England, in the event of non-confirmation at the end of the period of probation or on removal or dismissal, will receive a sum sufficient to cover her return journey to England. Every hospital will be in charge of a local committee, and the medical woman in independent charge of such hospital will be entitled to attend all meetings of the local committee. She will have full professional control of her hospital and such powers of administrative control as may be determined by the authorities financially concerned. She will not be under the civil surgeon in any way, but should she wish to do so, she can always call him in for professional assistance or consultation.

As regards the inspection of women's hospitals, it is proposed to associate with the Inspector-General of Civil Hospitals one of the senior medical women in each province, who will receive extra pay and travelling allowance for this purpose, but she will not be a full-time officer. She will make her visits of inspection in addition to any which the Inspector-General of Civil Hospitals may think fit to make himself, due regard being paid to *purdah*. She will also be expected to give sympathetic judgment, opinion, and advice to the younger women in charge of hospitals. It is proposed also that the inspection of the minor female branch dispensaries shall be entrusted to the medical woman in charge of the large hospital at the headquarters of the district concerned.

Lastly, the central committee, who will now be mainly responsible for the salaries of the medical women of this service, hope that the provincial committees will devote the funds they will thus save to increase their staff of female assistant surgeons, who will work as assistants to the medical women in charge of the larger hospitals.

REMARKS ON THE SCHEME.

This, ladies, is the scheme, which I think you will agree redresses all legitimate grievances and gives the medical woman in India an assured and definite position. It requires no further explanation on my part, but I should like, with your permission, to reply to one criticism that has been made on it, and also to offer a word of advice to any candidate who may think of entering the new service. The criticism to which I refer is to the effect that the rate of pay on first joining is inadequate, and that it will not attract the right type of woman. In reply to that I would point out that when you take into consideration the free house, the terms are better than those offered to young officers of the Indian Medical Service. Moreover, from the very beginning the medical woman has the opportunity of private practice, whereas the young officer of the Indian Medical Service spends his first five or six years in military employ, where he can have little or no private practice, whilst he has in addition all the expenses incidental to regimental life.

My word of advice refers to this same question of private practice. If you wish to be of real service to your poorer patients and also to be a successful practitioner amongst the better classes I recommend you to devote your six months of probation not merely to the study of tropical diseases, but also to learning the language and to making yourself acquainted with the customs and prejudices of the country. Learn to speak Hindustani as it is spoken by educated Indians; be not content with the horrible jargon that the average European uses in conversation with his servants. Study, moreover, Indian prejudices, especially as regards rules of diet in connexion with illness. If you fail to do so, much trouble awaits you. When you are called in to see an Indian patient, after the diagnosis, prognosis, and treatment have been discussed, the last question that will be put to you is, "What about diet?" If then you order an article of diet which according to Indian ideas is contraindicated in the class of disease with which you are dealing; if, for instance, you commit the horrible blunder of ordering milk in a case of bronchial catarrh, or rice for a patient suffering from malarial fever, the chances are that so soon as your back is turned your prescription will be torn up and you will never be called in again by that family. Above all, do not fall into the grievous error of regarding these prejudices as nonsensical. The longer you live in India and the more intimate your connexion with Indians the greater will be your appreciation of the wisdom of the ancients, and the more completely will you realise that the West still has much to learn from the East.

A few more words and I will bring this long discourse to a close. It is obvious from what you know of the size of India and from what I have told you as regards the medical needs of that vast continent, that these needs cannot be supplied merely by European agency, whether it be that of medical men or medical women. If, therefore, female medical aid to the women of India is ever to become a reality it will be necessary to utilise indigenous talent, and one of the most important duties of the new service of medical women will be to train Indian women and domiciled Europeans and Anglo-Indians for the profession of medicine. Hitherto, owing to the absence of a medical school exclusively for women, it has been practically impossible to obtain Indian women of a suitable class, but this difficulty has now been overcome. Her Excellency Lady Hardinge has collected a very large sum of money which will suffice for the construction and equipment of a thoroughly up-to-date medical college for women, attached to which will be a female hospital of about 150 beds and a training school for nurses. The Government of India has given an excellent site on the new Imperial enclave at Delhi, within half a mile of the railway station. We hope also to obtain a grant sufficient to cover the annual upkeep. This college will be entirely staffed by women, and it will offer to the new service of medical women opportunities for professorial, tutorial, and research work which they could not obtain in private practice. The construction of the college will commence very shortly, and the committee of management will consist of three women and two men. Meanwhile medical women are being, and will be, largely consulted as to its organisation, and it is proposed to appoint the lady principal a year before the college is opened in order that she may supervise the construction and superintend the arrangement of the fittings, equipment, and furniture.

I have said enough to show not only that India is in urgent need of the services of medical women, but that, under the improved conditions, it offers a splendid career to medical women of the right stamp.

I will not detain you, therefore, any longer, except to express the great pleasure it gives me that this scheme has materialised during my term of office as Director-General of the Indian Medical Service. Believe me, ladies, the members of the service which I represent are not hostile to the interests of medical women; on the contrary, we are your sincere well-wishers, and I feel very strongly that we have not deserved many of the bitter attacks which have been made upon us in recent years. India affords ample scope for physicians and surgeons of both sexes, whether they be officials or independent practitioners, and I trust that in the future the medical woman, now that all irksome restrictions are about to be removed, will cease to regard the civil surgeon as her natural enemy and will learn to look upon him as an esteemed friend and colleague, and that in the days to come medical men and medical women practising in India will work in complete harmony to their mutual advantage and that of suffering humanity.

ROYAL SANITARY INSTITUTE.—A British Columbia branch of this institute was formed in Vancouver in August. Lectures were given last winter, and it is hoped to continue the courses this year under the auspices of the institute. Dr. F. T. Underhill, medical health officer of Vancouver, is the chairman for the year, and Mr. R. Robertson the secretary and treasurer. There are 29 Fellows, Members, and Associates in British Columbia, and there is plenty of work before the branch.

Introductory Address
ON
MEDICINE AS A LIBERAL EDUCATION.

Delivered at the Opening of the Winter Session of the Medical School of the Middlesex Hospital,

BY W. SAMPSON HANDLEY, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO OUT-PATIENTS AT THE HOSPITAL.

GENTLEMEN,—My first duty—a very pleasant one—is to say a word of welcome, brief but hearty, to those who have just joined us, the new students. They may be feeling a little strange and a little lonely. Let me then assure them that to-day by joining the hospital they have made many friends, and that we older Middlesex students, their teachers, give them a warm welcome. We desire them to feel that they can talk to us freely about their difficulties in the present and their hopes and plans for the future. Potentially, they are the most important people present to-day, for to them it will be given to guard the traditions and to mould the future of this hospital. We are proud of our past, but we think more of our future, and we see it visualised in the men who have just joined us. The buildings in which Charles Bell, Thomas Watson, and Burdon Sanderson taught were full of memories, but they are disappearing, so that a new building may arise better suited to modern needs, and especially to modern methods of research. Let me tell the men who will inherit that building that the hospital demands of them their loyalty and service. It bids them cease to be isolated individuals and become members of a commonwealth, wheels in a vast machine, and parts of a great whole. The fulness of their response to that appeal will be a measure of the future greatness of the hospital, and of their personal happiness while they work within its walls.

DISTINGUISHED MEN WHO FORSOOK MEDICINE.

In the brief time at my disposal I propose to draw your attention to the careers of some distinguished men who, after commencing life as doctors, have adopted another profession. My object in doing so is to show you that medicine is not a mere technical training, but that it forms one of the best means of developing a man's powers in whatever direction those powers are later to be applied. In other words, a medical training is a liberal education. The lifelong exercise of the art of medicine may tend ultimately to narrow the outlook, but this is an entirely separate question which does not now concern us. It occurred to me that if some of the distinguished renegades of medicine could be induced to collaborate in writing my address for me I should be doing a kindness both to my audience and to myself, while at the same time I could reserve to myself the sole merit of the authorship of their joint production. I regret to say that this well-conceived design has miscarried. I can, however, give you several authoritative estimates from men educated in medicine of its influence upon their subsequent non-medical career. Of such men the great historical prototype is the patron saint of medicine, St. Luke, the beloved physician, the biographer of his Master. Doubtless there are many men who, like St. Luke, have abandoned medicine for the ministry. The recent history of this hospital supplies an example in the person of Canon Arnott, now, and for the past 28 years, rector of Beckenham, who is a Fellow of the Royal College of Surgeons, a distinguished pathologist, and the author of a work on cancer. Canon Arnott was formerly on the staff of this hospital as assistant surgeon. In entering the ministry of the Church he realised a youthful ambition, deflected for a time to medicine by parental wishes. Canon Arnott, I believe, rigidly abstains from any exercise of his old craft of surgery, whether by way of advice or practice, and this appears to be the safe general rule of those who leave the profession. His busy life in a large parish with four churches has left him little time to keep up his old and still vivid pathological interests. But he gives me leave to tell you that while medicine has no direct value in his present field of work, the old scientific training, the long hours spent in microscopic work, the power of sympathy with suffering, the realisation of the inexhaustible study and experience needed for anything like dogmatism in the ways and by-ways of nature, the humility necessary before the baffling problems of life and disease and death—all this is of incalculable value in his present profession. He speaks, too, of the knowledge of men and affairs which medicine gives, and of the intimate acquaintance with the seamy side of life to be gained perhaps better in a hospital surgical out-patient practice than anywhere else. Such is his personal estimate of medicine as a liberal education.

Keats and Goldsmith.

Of those who have forsaken medicine for poetry the most distinguished is perhaps the poet Keats, who was a qualified medical man and a Licentiate of the Society of Apothecaries. No trace of his medical knowledge is visible in the poems, but that medicine had important lessons for him may be judged from a comparison of the two following quotations: "My last operation was the opening of a man's temporal artery. I did it with the utmost nicety, but, reflecting on what passed through my head at the time, my dexterity seemed a miracle, and I never took up the lancet again." The second quotation refers to his poem "Endymion." "Had I been nervous about it being a perfect piece, and with that view asked advice, and trembled over every page, it would not have been written, for it is not in my nature to fumble." There speaks the surgeon, trained by his profession to the initiative which is so difficult for a man of poetic temperament. It is quite possible that but for his medical training Keats's vigorous self-criticism would have overcome him, and that his poems would never have been written.

After ineffectual attempts to qualify in divinity and in law, Oliver Goldsmith obtained a mysterious medical degree in the University of Padua during the course of his wanderings through Europe. Owing to the death of his benevolent uncle at this juncture he was thrown upon his own resources. With the aid of his flute he wandered homeward through France, and reaching London, he commenced medical practice in Bankside, Southwark, a locality once the site of Shakespeare's theatre, which is now given up to gigantic warehouses. Here he was seen by a Scotch acquaintance in the tarnished finery of a second-hand suit of green and gold, with a shirt and neckcloth of a fortnight's wear. Later he appeared in a full-trimmed suit of rusty black velvet with a patch upon the left breast which he adroitly covered with his hat during his professional visits, resisting politely but firmly courteous invitations to put down his hat. Practice was slow in coming, and Goldsmith decided to try for a medical appointment in the East India Company's service, at one of their factories on the Coromandel coast. Wealth beyond the dreams of avarice seemed within his grasp, for the salary was £100 per annum with private practice, but his utmost efforts at hack literary work failed to raise the sum required for his outfit, and the fair prospect vanished. Shortly after, in 1758, he presented himself at the College of Surgeons for examination as a surgeon's mate. Though the outer man was well furnished with a brave suit of clothes made for the occasion and to be paid for with four magazine articles, the examiners rejected him. He accepted their verdict as final and abandoned medicine. It seems, indeed, improbable that Goldsmith ever possessed more than a mere smattering of medical knowledge, and this is borne out by his pathetically careful attempts to dress for the part he was so ill-fitted to play. The fate of his examination suit of clothes well illustrates his delightful character. Four days after the examination he pawned it at his landlady's entreaty to deliver her husband from a debtor's jail. The suit not being paid for, poor Goldsmith himself narrowly escaped arrest at the hands of the irate tailor.

It is worthy of note that the present distinguished Poet Laureate has the Oxford medical degree and is a Fellow of the College. Mr. Bridges has educated himself for his high calling with a persistence worthy of Milton. After leaving Oxford and spending some years in travel, he set to work to supply the defects of a classical training, and having decided that medicine offered the most direct way of getting scientific education (a conclusion which I commend to your particular attention), he entered at St. Bartholomew's Hospital, where he became casualty physician. He was also physician at the Children's Hospital and at the old Great Northern Hospital. It is not difficult to see how his

poetry must have gained in directness and humanity from his years of service to the London poor, which balanced and harmonised the complex elements of his intellectual training and prevented that atrophy on the volitional side which is the bane of a purely literary career.

Law and Politics.

The lawyer's training in dialectics and in the use of the spoken word gives him an overwhelming advantage in political warfare, quite apart from the profound knowledge of business and of human nature which legal experience brings. Thus in political life the law carries all before it, while the successes of medicine have been attained rather on the administrative and diplomatic sides than in the field of debate.

The careers of the late Lord Ilkeston, formerly Dr. Walter Foster, and of Dr. Jameson, lately Premier of the Dominion of South Africa, are too familiar to need more than a passing mention. Sir George Robertson, one of the heroes of the siege of Chitral, has to his credit a long and varied record of fighting and diplomacy among the wild tribes of the Indian frontier, where he proved himself an unrivalled manager of men. Few may know that his first ten years in India were spent in the Indian Medical Service.

Among doctor-politicians must also be reckoned Dr. George Ernest Morrison, who is an M.D. of Edinburgh University. Before the age of 21 he crossed Australia on foot from north to south. His subsequent travels carried him to the most inaccessible parts of China, and on one occasion he rode from Central China to Russian Turkestan, 3750 miles, in 175 days. Present at the siege of Peking, where he won fame as the omniscient *Times* correspondent, he is now the official political adviser of the President of the Chinese Republic, a post which at present would appear to be no sinecure. His name naturally recalls that of Dr. Sun Yat Sen, the first student of the English medical school established at Hong-Kong by Mr. Cantlie, and the organiser of the movement which led to the downfall of the Manchus. Whatever be thought of the political wisdom of his stupendous achievement, his disinterested patriotism seems beyond question.

Among distinguished lawyers recruited from the ranks of medicine must be mentioned the Right Hon. Sir Robert Finlay, Member of Parliament for Edinburgh and St. Andrews Universities, and a former Lord Rector of his own University of Edinburgh. The son of an Edinburgh physician, he graduated in medicine at Edinburgh, and was then called to the Bar. His brilliant subsequent career as Solicitor and Attorney General proves, at any rate, that a medical education offers no insuperable obstacle to subsequent legal success.

Art.

The late Sir Seymour Haden, founder and President of the Royal Society of Painter Etchers, the leader, along with Whistler, of the revival of etching in England, and one of the greatest exponents of the art, was a surgeon, and no mere dilettante one, for he studied not only in London but in Paris and Grenoble, had obtained the Fellowship of the College of Surgeons, and practised as a surgeon until the age of 52. He considered etching rather as a recreation than as the serious business of his life, so that his etched plates number only about 200 in all. Perhaps he gave too much of his life to medicine. If his art had been the single passion of his life he might have been the English Rembrandt. But he had that sanity and love for a balanced life which has often characterised gifted Englishmen, and he refused to become the slave of his genius. The same struggle and the same victory is exemplified in the career of Robert Browning, who managed to become a poet, and a great one, without ceasing to be a man of the world.

Mr. Henry Tonks, assistant professor at the Slade School of Fine Art, is another instance of the doctor turned artist. Many generations of students have felt for him the affection not unmingled with wholesome dread which Sir Henry Morris used to inspire here. Deeply interested in his work and his students he will permit no slack worship at the shrine of Art. Mr. Tonks has sent me a delightfully frank letter in which he says:—

> It will be impossible for me to answer your letter in a satisfactory way unless I speak actually of my own experiences in a way that may seem hardly becoming; nevertheless, that is what I will do. As an artist I naturally very much regret that I lost so much valuable time in doing other things than learning to draw, which is the foundation of an artist's work. Yet I know very well that the years I spent in preparing myself for the life of a doctor were of the greatest importance to me As human beings are the most interesting things on earth, and as everything else is a background to them, the more you know about them in structure and mind the better are you able to express your ideas about them. ..... It is really impossible for me to say how much I learnt from the medical profession, as it has all become so much a part of my being, and if by a miracle I could begin again I should be torn by the desire to know what I do and by the feeling that I was losing time in my preparation to be an artist. Fate fortunately decides these things for us. To be a specialist in any one thing is naturally good for the practice of that thing, but sometimes it is better to lose a little to gain a great deal.

Mr. Tonks goes on to say that a disadvantage of medicine is that it has become so vast that a young man has to leave much unlearnt and even unthought of. Here I would dissent from him, for it is one of the greatest advantages of medicine that, like a sea training, it brings a man up against the mighty forces and the vast complexity of nature, and teaches him his limitations. This, indeed, Mr. Tonks implicitly admits when he adds: "I think the reason why some professors are bores and prudes is that they have had so little time to see the relation of their subject to anything else."

You will all admit that no actor on our stage can give advice to youth in difficulties with such suave yet overwhelming authority as Sir Charles Wyndham. His celebrated "It won't work" speech in the last act of *The Liars* is perhaps the best instance that can he quoted. It is the physician in him coming out, for Sir Charles, now an acknowledged head of the dramatic profession, is a qualified medical man, and doubtless one of the lost leaders of medicine.

Science and Literature.

Sir Joseph Hooker, the director of Kew Gardens for 20 years, and a former president of the Royal Society, who died as recently as 1911 at the advanced age of 94 years, was perhaps the last survivor of the great Victorian men of science. Like Huxley he began his career as a naval surgeon, and obtained his chance of scientific distinction as surgeon to an exploring expedition, the chance which some of us who stay at home seek at the end of a microscope, and though bounded in a nutshell, count themselves the kings of infinite space. After Hooker's return from the Ross expedition to the Antarctic, to which he acted as surgeon and naturalist, he seems to have experienced a violent and very natural revulsion of feeling, for we find him next among the luxuriant vegetation of India, basking in the blaze of rhododendrons. He had found his vocation. His great claim to distinction is that by his studies on the distribution of plant life he produced what amounts to a botanical map of the world; and it was medicine which introduced him to botany.

Your familiarity with Huxley's career absolves me from speaking of it in detail. Like the career of Hooker, it illustrates a great practical advantage of a medical training, to which I may here call attention. It is a key, albeit not a golden one, which unlocks the pageant of the world. In this respect it has no rival among the pacific professions. The law and even the church must stay at home when the poles have to be reached or an unknown territory crossed. But the doctor cannot be spared. The steamship companies will show him the gorgeous East and provide him with pocket money if he cares to take a voyage as ship's surgeon. There are few parts of the world to which the exercise of his profession will not take him if he so desires. His training in observation has prepared him to use his privileges; witness the careers of Hooker and Huxley. A man can hardly have a medical training without being able to say with one of Mr. Morley Roberts's characters: "I sees what I looks at," and, as explorers, doctors have been very successful. I need only recall to your memories the careers of Livingstone and Mungo Park.

Among those who have left medicine, though his heart is still with us, we must perhaps count our former colleague, Mr. Stephen Paget. Gifted with too complex an intellectual outlook, and torn between the claims of science and of literature, Mr. Paget has solved the problem of serving two masters in a unique way by becoming the literary protagonist of science. His work as secretary of the Research Defence Society is of incalculable value to the cause of science in this country.

Among the novelists medicine is represented by Sir Arthur Conan Doyle, whose debt to his medical training is a large and a direct one, for did he not discover Sherlock Holmes in the person of one of his surgical teachers at Edinburgh?

THE EDUCATIONAL ADVANTAGES OF MEDICINE.

You will see from the examples I have given you that the renegades of medicine include an unduly large proportion of men who have subsequently reached eminence in other spheres of activity. Now the class is not a large one, for few men leave our profession, a fact dependent on its inherent interest and attraction. It is then a fair inference that the study of medicine provides a liberal education, one which so develops the individual that it fits him for any of the varied calls life in its other departments may make upon him. The renegade doctor is likely to be found near the top of his particular tree. You will probably accuse me of unduly depreciating the accepted forms of liberal education, and it is perfectly true that science is no substitute for a literary and linguistic training. I maintain only that it is their necessary complement. Attempts to make science the main ingredient of school education are predestined to failure. They fly in the face of the great biological generalisation that the development of the individual is an epitome of the development of the race. The human embryo begins as a unicellular organism and passes through a stage in which it possesses gill-slits like a fish before it assumes the final mammalian form. In accordance with this principle, which seems to me to supply the key of some educational difficulties, the attention of the boy is rightly directed to the preoccupations of earlier civilisations, to language, classics, and history. A scientific man, if denied the power of expression which only a literary training can give, is deprived of most of his power to influence his fellows. But given the literary foundation, an acquaintance with natural science, the most recent achievement of the race, is necessary to complete the edifice. This training will naturally fall in the university or post university stage of education.

For the general purposes of life I believe, with Mr. Bridges, that medicine, which blends with and merges into pure science in every direction, is the best way of getting a broad general acquaintance with scientific thought. As compared with pure science it has the advantage that it does not exclude the human interest, and that it breaks down that morbid dread of plebeian contact, that want of recognition of the dignity of service, which is not infrequently seen in the educated Englishman. Goethe, who studied medicine and acknowledged its charm, says: "My disgust at the patients gradually decreased as I learned to forget their physical condition in the ideas suggested by it, which rendered possible the restoration of human form and human life." The personal service which the medical student cheerfully gives to the more unfortunate of his fellow citizens, the intimate contact he makes with their miseries and heroisms, virtues and vices, must tend to broaden his outlook on life. He who washes the beggar's feet may find his own hands whiter than before.

Time forbids me to discuss fully the educational advantages of medicine, though much might be said. As a training in resourcefulness and presence of mind it is as good as the fighting services, for its opportunities are daily ones.

In this connexion I may remind you of the repeated testimony borne by our national hero, the late Captain Scott, to the practical wisdom of his medical comrade, Dr. E. A. Wilson, to whose judgment one and all appealed in matters small and great. Like the middy on the torpedo boat, the medical man gets his responsibilities early. The house surgeon just qualified must be prepared at any moment to perform tracheotomy, a delicate operation in which death will call an immediate checkmate to any false move. And he must do it publicly before the critical eyes of his fellow residents. The fact that he usually does it so well shows the excellence of his previous training.

THE VALUE OF SCIENTIFIC KNOWLEDGE TO THE STATE.

I have no wish to institute comparisons between medical training and the established forms of liberal education. As Sir Oliver Lodge said recently: "Let us not fall into the old mistake of thinking that ours is the only way of exploring the multifarious depths of the universe, and that all others are worthless and mistaken. The universe is a larger thing than we have any conception of, and no one method of search will exhaust its treasures."

But for this very reason some of those fortunate people who have leisure for full self-development should complete it through science. In our national leaders, collectively if not individually, we have the right to expect that combination of literary and scientific training which was the source of Goethe's strength. Only thus can the complexity of the universe be properly reflected in their intellectual equipment. In my opinion that is not at present the case. To take a crucial instance, I have not been able to ascertain that more than one member of the present or the last Cabinet has received an education in natural science. It is not sufficient that the man of science should be at hand to be consulted; the scientific habit of mind must be directly represented in the national councils. Let me try to illustrate the evils attending the present state of things.

Last June Mr. Balfour, whose sympathies with science we gratefully acknowledge, opened some new buildings of the National Physical Laboratory at Teddington, the institution which tests and standardises optical and other instruments and undertakes physical researches of public interest. Among a number of subjects it has taken up this year one alone, the testing of roads and road surfaces, touches the expenditure of millions of public money annually and affects the comfort and well-being of the whole nation. Is it not extraordinary that this institution—national in the fullest sense—should be dependent on private generosity for necessary extensions to its buildings? Yet such is the fact. The spectacle is as grotesque as that of a millionaire inviting subscriptions among his friends to provide his steam yacht with a compass. I present this idea to the Gilbert of the future, and suggest "We can't afford a compass, so we'll go to sea without," as the refrain of the final chorus. In sober fact, the phrase represents not inaccurately the present attitude of the nation towards science.

Lord Beaconsfield's purchase of the Suez Canal shares for the nation is now hailed as a stroke of financial genius. The statesman who demanded of Parliament half a similar sum for the endowment of the University of London with a department for the investigation of tropical disease would make a better investment for his country even from a monetary point af view.

Another of our statesmen, Mr. Austen Chamberlain, continuing a work begun by his distinguished father, is attempting with great personal devotion the task of raising a fund for the London School of Tropical Medicine, an institution on which, believe me, the future of the British Empire largely hangs. But while we see our statesmen supporting science by their sympathy and private efforts, we shall not find them adequately exerting their authority in Parliament in the same cause until some of them receive a scientific education. The safety and progress of the State is as much bound up with national progress in scientific knowledge as in the maintenance of an adequate navy.

You may think that I use the language of exaggeration, but when you reflect that the Panama Canal has only been rendered possible by laboratory investigations dealing with an obscure mosquito, suggested in their turn by Sir Ronald Ross's investigations on the mosquito which carries malaria, you will agree that I have not overstated the case. Here is a little piece of scientific knowledge which could be written on a visiting card: "The stegomyia mosquito is the vehicle which carries the organism of yellow fever from man to man." Without this knowledge the French attempt to cut the Canal ended in the waste of many thousands of lives and £50,000,000. Knowing this secret the American engineers and doctors have succeeded. It may ultimately be realised that the expenditure of money in scientific research and in the support of institutions for the advance of knowledge is not the mere luxury of a rich nation, but one of the surest means of increasing the national wealth as well as the national happiness.

It is interesting to note that in the opinion of Pasteur, the great French scientist, the downfall of France in the war of 1870 was due to the national neglect of science. Under the first Napoleon science had flourished. For his expedition to Egypt he had organised a special staff of scientific men to accompany him. He had such a respect for the discoverer of vaccination that he never refused a request from Jenner for the release of an English prisoner.

What happened later in France may be expressed in Pasteur's words: "A victim to her political instability France has done nothing to keep up, to propagate and to develop the progress of science ..... ; she has lived on her past, thinking herself great by the scientific discoveries to which she owed her material prosperity, but not perceiving that she

was imprudently allowing the sources of those discoveries to run dry. ..... While Germany was multiplying her universities, ... creating vast laboratories amply supplied with the most perfect instruments, France, enervated by revolutions, ever vainly seeking the best form of government, was giving but careless attention to her establishments for higher education."

After the war it was to science that Pasteur mainly looked for the regeneration of France. His opinions might be dismissed as an expanded version of the cobbler's dictum that there is nothing like leather. They may appear as high-sounding generalities, possibly containing a portion of truth, but mainly expressive of a natural loyalty to his scientific colleagues, or of a narrow-minded enthusiasm. They might even be ascribed to veiled self-glorification. But Pasteur, who never dealt in vague generalities, devoted his life to proving their truth. And it was computed by Huxley that, apart from the human lives they have saved, the material benefits his researches brought to the brewing, farming, and silkworm industries of France sufficed to pay the vast war indemnity which the victors exacted.

You will see now why I believe that one of the most urgent needs of the day is the presence among our leaders, who at present receive almost exclusively a classical, a literary, or a legal education, of a larger number of men who have had a scientific training. To those ambitious young men who aspire to mould the destinies of their country I would say: Leave the past when you have attained your degree in arts and come where knowledge is alive and growing. Come among us and spend a strenuous five years in securing the scientific knowledge and the mental discipline which medicine is capable of giving. In your subsequent career of politics or public service of whatever kind you will find that the time has been well spent, and that the skill you have acquired in applying precise knowledge of many kinds to the service of humanity finds many applications in the wider spheres to which you may be subsequently called.

Introductory Address

ON

THE WORK OF THE MEDICAL PROFESSION IN INDIA.

Delivered at the Opening of the Winter Session of the Medical School of St. Mary's Hospital on Oct. 1st, 1913,

BY SIR JOHN P. HEWETT, G.C.S.I.,

LIEUTENANT-GOVERNOR OF THE UNITED PROVINCES OF AGRA AND OUDH.

GENTLEMEN,—The invitation from Sir John Broadbent to preside at this gathering was as agreeable to me as it was unexpected. It is a great honour to be given the opportunity of expressing in public my admiration for the accomplishments and devotion of the profession which the students at St. Mary's Hospital Medical School have chosen to follow. It is one of the noblest that a man can undertake, and perhaps the only one that will command the same regard and esteem to the end of time.

When asked to give an address on this occasion I found great difficulty in selecting a subject, but, after considerable thought, it occurred to me that it might not be inappropriate were I to attempt to give you some information as to what has been effected in India by medical men, and to endeavour to convey some idea of the enormous field that still lies open to them there.

VITAL STATISTICS OF INDIA.

The registration of births and deaths has only been attempted in India for about the last 40 years, and, as most of the reporting agency is illiterate, the causes of death are very incorrectly recorded though the number of deaths is reported with fair accuracy. Specific fevers, such as malaria, small-pox, and influenza; abdominal diseases, such as cholera, dysentery, and diarrhœa; and lung diseases, such as tuberculosis, pneumonia, and bronchitis, are those which cause the greatest havoc among the Indian population. You will readily understand how difficult it is to ensure even approximate accuracy in reports of the cause of death. Moreover, nearly 71 millions of the population of 325 millions live in the Native States to which the rules and regulations in force in British India do not apply. My remarks therefore refer only to the 254 millions resident in British India. The annual death-roll in British India amounts to about 7½ millions, of which about 40 per cent. occurs among infants. This figure sounds appalling, and so does the fact that nearly 7 million persons have died from plague in British India since it last reappeared in 1896. Remarkable as these figures are, it is perhaps even more extraordinary that the country should, in spite of them, be, so far as the increase of its population is concerned, in a condition which would be envied by some European nations. The average death-rate during the past 10 years has been 34 per 1000, or, if deaths from plague are eliminated, 31·5 per 1000. In the same period the birth-rate has averaged slightly over 38 per 1000, with the result that the births reported have exceeded the deaths by about a million in each year of the decade. Though it is indisputable that the public health has improved in many respects in the past half-century, the data available are not adequate to enable us to gauge the extent and manner of the improvement. And whatever the improvement already effected, the main reflection about these figures must be that if we describe the problem which still confronts the medical profession in India in the direction of reducing infantile mortality, malaria, and other fevers, and abdominal and lung diseases as being one of portentous magnitude we shall not be using an expression of exaggeration.

IMPROVED HEALTH IN ARMY AND IN JAIL POPULATION.

When we turn to the classes to whose well-being medical science has been specially directed, and regarding whose condition accurate statistics over a lengthy period are available, the results are most encouraging. These classes are the army and the jail population.

The mortality among British troops serving in India was 55 per 1000 between 1770 and 1800, 84 per 1000 between 1801 and 1830, and 58 per 1000 between 1831 and 1856. The Royal Commission of 1863 took a death-rate of 20 per 1000 as a possible rate under improved sanitary conditions. In the ten years ending in 1878 the death-rate had been reduced to 19·8. It has since 1900 averaged 9·5, and in 1911 was 4·89. Making all allowance for the fact that in the earlier years of our occupation the mortality on service was high these results are extraordinarily good. The mortality among the wives of soldiers has been reduced to one-third of what it formerly was, and that among their children to one-half. The diseases mainly responsible for the high death-rate among the British troops in the past were enteric fever, abscess of the liver, and cholera and other epidemics. The death-rate among the native troops, among whom pneumonia is the most fatal disease, was between 1871 and 1880 over 20 per 1000, and in the last six years of last century 11·7 per 1000. In 1911 it had fallen to 4·48 per 1000, or if deaths among men on sick leave or furlough are included to 6·78. The medical officers in charge of our army in India have indeed achieved a record of which they and all the members of their profession may well be proud.

The results among the jail population have also been very satisfactory. Here the most common causes of death are dysentery, pneumonia, and tuberculosis of the lung. The number of deaths from epidemics is very small; fewer men in jail, for instance, succumb to plague than in the native army. From 1831–1856 the mortality in jails averaged 71 per 1000; in the decade between 1869 and 1878 it was reduced to 49; in the last five years of last century it was 30. Since 1900 it has averaged 20·5, and in 1911 was between 18 and 19. I may, perhaps, mention an instance of the beneficial effect of the supervision of a jail by a medical officer which came under my immediate notice. It was at one time the practice to place some of the larger jails under superintendents who were not medical men, the medical work in the jail being undertaken by a subordinate native medical officer, subject to the superintendence of the health officer of the district who had many other duties and was only expected to pay one visit daily. The death-rate in this jail for some years had been about 50 per 1000, and it had even gone considerably over 60. After studying the condition and statistics of the jail it seemed to me that the medical supervision was not adequate. I therefore determined to appoint a medical officer to the sole charge of the jail. The most remarkable

result ensued: within one year the mortality was reduced to just over 19 per 1000.

Towards the results in cantonments and jails sanitary improvements of all kinds, a purer water-supply, and a better system of drainage have contributed in no small degree. But there are enormous areas, including most of the villages in India, in which there are no sanitary arrangements whatever worthy of the name, in which the water-supply is impure, and in which there is no system of drainage at all. And there is scarcely any place, whether city, cantonment, or village, in which there are not defects in hygiene so glaring as to shock the sanitary reformer. The Government of India are doing all that lies in their power to remedy these defects. They have given in recent years enormous sums of money towards sanitary improvements, and have neglected no opportunity of encouraging the people to pay more attention to hygiene. But progress is necessarily slow, and improvement must be gradual if it is to be permanent.

BENEFITS DERIVED FROM EXPERIMENTS ON ANIMALS.

I have had the honour to be associated as an administrator with medical officers in combating certain diseases in India, and the experience gained in this work has afforded the clearest proof that, but for the knowledge acquired by means of experiments on animals, the prevention and treatment of some of the most grievous afflictions of the human race in India would have been far less successful than they have been. Some people affect to consider that medical men are prejudiced in their defence of vivisection and other experiments on animals. This insult to the members of a most honourable profession tempts me to say a few words on the subject. I have no claim to speak with any approach to the authority of Lord Cromer, whose introduction to Mr. Stephen Paget's excellent book "For and Against Experiments on Animals" is a model alike of style and judicial reasoning. But I can at least claim to have had some opportunity of estimating at first hand the value of certain methods of treatment which depend on experiments on animals. And I can point to the fact that, when associated with my friend Sir Almroth Wright on the Indian Plague Commission, I felt bound to differ from him on some very important matters discussed in our report, such, for instance, as compulsory corpse inspection in plague epidemics, as proof that prejudice has played no part in the opinion that I have formed as to the results of those methods.

SMALL-POX AND VACCINATION.

I would first refer to the statistics regarding small-pox. There is a Hindu goddess of small-pox called Sitla, in whose honour religious fairs are held and largely attended. The disease prevails to an extent unknown in modern Europe, and its evil effects are aggravated by the fact that an enormous number of those who contract it never receive any medical treatment during the attack. It was not till about 1850 that a serious attempt was made to introduce vaccination into India. In that year some 350,000 persons were vaccinated; the number annually vaccinated in these days approaches 10 millions. The death-rate from small-pox, which 30 years ago was nearly 1 per 1000, has steadily declined until it is now only about one-third of that amount. Moreover, it has been noticed that the number of pock-marked young people of both sexes is far smaller in the present day than was formerly the case, and that, while the proportion of the wholly or partially blind among the young used to be highest where small-pox was most prevalent, it has decreased in general accordance with the territorial spread of vaccination. I submit that no fair-minded person can avoid the conclusion that these results have been due to vaccination. In the face of the clear proofs of its efficacy it is surely calamitous that the opponents of vaccination in England should have set themselves to make the people of India hostile to a process which has brought them so much benefit.

INOCULATION AGAINST PLAGUE.

I have already referred to the terrible mortality from plague in the last 15 years. It has long since been recognised that, except in extraordinary circumstances, compulsion is impossible, and the great obstacle with which the Government has been confronted is the difficulty of convincing the people of the utility of particular methods of prevention or cure. It is not easy to appreciate the mental attitude of people who, without having made a serious study of the facts and figures pertinent to the question, have increased the difficulties of those doing their best to contend with this terrible scourge by asserting that the vaccine discovered by M. Haffkine has encouraged the spread of the plague in India. There have, of course, been instances in which evil results have been caused by particular doses having been unfit for use, or by the carelessness of individuals injecting the vaccine, but such cases have been rare, and the use of the vaccine has been, speaking generally, of enormous benefit. The conclusion at which we members of the Plague Commission unanimously arrived in 1899 was that "inoculation with Haffkine's prophylactic vaccine sensibly diminishes the incidence of plague attacks on the inoculated population, though the protection which it affords is not absolute; that it also diminishes the fatality of attacks; that its protective effect does not appear within the first few days after the inoculation, and that the protection lasts certainly for some weeks, possibly for some months."

Since this conclusion was formulated I have had, as the head of the Government of two provinces in succession, one with a population of 47,000,000 and one with a population of 14,000,000, to deal continuously with outbreaks of plague. The whole of my experience gained in this interval has confirmed the conclusion of the Plague Commission, and the statistics of the many epidemics in which inoculation has been practised under my own eyes go to prove that the use of Haffkine's vaccine has been of the greatest service in protecting people from plague. I could quote many cases, but I will content myself with one which has always impressed itself very much on my mind. A Parsi friend of mine, Sir Bezonjee Dadabhoy, the manager of the Empress Mills at Nagpur, in which city some years ago a serious epidemic resulting in the death of over 7000 people occurred, endeavoured to induce the whole of the operatives of the mills to be inoculated. The total number on the muster rolls was between 6000 and 7000, and the daily attendance between 4500 and 5500. The number of mill hands inoculated was 5046. Among the comparatively small number of uninoculated there were 118 deaths, while among the inoculated there were only 9 fatal cases, 6 of which were the result of an attack within 10 days of inoculation.

This is a report from one whose only interest was to benefit the operatives in his employ, and the facts narrated in it prove conclusively that by inducing them to be inoculated he secured protection for them during the epidemic.

Antityphoid Vaccination.

Turning to enteric fever, the first thing that claims attention is that it is much more prevalent among Europeans than among Indians. For many years it was chief among the fatal diseases prevalent in the British army in India. In the last five years of the last century 43 out of every 100 deaths among British soldiers were due to enteric fever. The greatest liability to suffer was between the ages of 20 and 25 and during the first year of service in India, the liability of men to contract it in the first year of service being at least twice as great as in any other period. At the end of last century the possibility of life would have been as good for the European troops in India as for males of the same age in England had it not been for the prevalence of enteric fever.

The chief task then before the medical officers employed with British troops was the reduction of the liability of the British soldier to enteric fever. In 1898, only 15 years ago, the mortality from this cause was over 10 per 1000; among the native troops it was the same time something between 0·01 and 0·02 per 1000. The use of Sir Almroth Wright's antityphoid vaccine was attempted about this time in a spasmodic way, but it was not till 1903 that this plan of fighting enteric fever became general. In that year 295 deaths were caused by enteric fever, and the mortality caused by it was over 4 per 1000. Since then the death-rate declined, till in 1910 it was 0·63, and in 1911, the number of deaths being 24, only 0·33. In the latter year there were 61,822 men protected by vaccination and 9552 not protected. Among every 1000 of the non-protected men there were 6·7 cases and 1·15 deaths, while among every 1000 of the protected there were 1·7 cases and 0·17 death. We must not, indeed, forget that a great deal has been done in the direction of isolating convalescents and bacilli-carriers, but these figures, like those regarding men in the army in France and America, conclusively prove the beneficial results of antityphoid inoculation.

A striking instance came under my observation at a

military station where outbreaks of enteric fever were of very frequent occurrence. The introduction of antityphoid vaccination resulted at once in a large diminution in the number of cases and deaths. In 1912 out of 693 men serving in four batteries of artillery stationed there 687 were protected by inoculation. There were in that year two cases among the six unprotected men, but only one case among the 687 who had been protected. The officer commanding a battery serving there wrote to me recently that all of his men had been inoculated for some years. He added, "I have never lost a man since, nor have I had a case of enteric that I can remember till this year. When I remember the number we used to lose in a battery each year I am astounded at Sir Almroth Wright's genius!" I can supplement this with my 35 years' experience that from the time when I first went to India till the use of Sir Almroth Wright's vaccine became established the cemeteries in the cantonments of the United Provinces were strewn with the graves of young men who had gone to serve their country in India only to be carried off by enteric fever within a year or two of their leaving home. Now that the death-rate even in a newly arrived regiment has fallen to what it might be expected to be in England the conditions have completely changed.

Snake-bite and Hydrophobia.

It remains for me to refer to two risks to life in India from which people in Great Britain are entirely exempt. Some 22,000 deaths are annually reported in India as having been caused by snake-bite. Admitting that this figure includes a number of deaths due to other causes there is still a large residuum really due to snake-bite. Antivenins which will, if promptly administered, prevent the bite of the cobra and Russell's viper respectively—two of the most poisonous snakes met with in India—from being fatal have been discovered by means of experiments on animals, and it is to be hoped that further discoveries may result in making similar treatment of the bites of other poisonous snakes feasible.

An even more terrible scourge than snake-bite is hydrophobia. Inhabitants of Great Britain are, owing to the foresight and firmness of Mr. Walter Long, saved from all apprehension on this score. It is vain to hope that the disease can ever be exterminated in India, where pariah dogs, jackals, and wolves alike can convey rabies. Till the end of the last century a patient bitten by a mad animal had no remedy in India. Only the well-to-do could afford a journey to the Pasteur Institute in Paris, and, owing to the length of the voyage, this might often be undertaken in vain. The poorer classes could only suffer and die in silence. In 1900 a Pasteur Institute was established at Kasauli. The number of cases received at the institute between 1900 and 1911 was 13,540, the patients being of every rank of life. There were 225 deaths in cases in which the treatment could not be applied in time, and 81 failures in which the patient died more than 15 days after the completion of the course. But the treatment as a whole shows a splendid result. The long distances that have to be travelled in India made it evident that one institute was inadequate. One most pathetic case occurred of a young English lady who, while expecting her first child, was bitten by a mad dog during the hot weather in the South of India. She had to undertake a terribly hot railway journey of nearly a week. Her case proved to be too advanced for hope, and she died in terrible agony. A second institution has since been established in the South of India and a third is to be established in Burma. When this arrangement has been completed some institute will be fairly accessible from any point in the territories under the Government of India, and provision will have been made to prevent an enormous amount of terrible misery, though with the number of habitations scattered over the country it will be impossible to prevent many cases from failing to come under treatment.

CLOSING REMARKS.

What I have attempted to tell you to-day will, I am sure, satisfy you that experience in India, as elsewhere, proves conclusively that operations on animals have afforded untold benefits to the human race. Performed with the utmost care by skilled surgeons, they are rendered almost painless through the use of anæsthetics, and are followed by a drug-softened death. As instances of cruelty to our dumb friends, how can they possibly be compared to the limitless sufferings imposed on beasts of burden and other animals, on whose aid mankind depends, in India and many foreign countries? One experiences every day in an Indian city horrors in the treatment of animals, inconceivable to the stay-at-home inhabitant of these isles accustomed only to the pampered pets and well-fed cattle of himself and his neighbours. What a field for the tactful energy of animal lovers there is in that vast country, where pity rarely impels the passer by to put a wounded and stricken animal out of pain instead of leaving it to die a lingering death; where beasts of burden of all kinds are systematically over-loaded and regularly worked when they ought to be in the care of the veterinary surgeon, and where even the cow, the sacred animal of the Hindus, is confined in evil-smelling and ill-ventilated hovels, and often milked by the horrible phuka system which causes it terrible suffering. At present only one institution, enfeebled through lack of funds, makes spasmodic efforts to instil into the starved brains of owners and drivers of beasts some dim recognition of the fact that consideration shown to their cattle is likely to reflect substantial gain on themselves. For lovers of animal life, for those whose earnest wish it is to save the beasts of the field from unnecessary cruelty, and to ensure for them the minimum of harshness and pain involved in their use in the service of man, there is in India a splendid field for benevolent work which will, like mercy, be twice blessed in bringing relief to the animals which now suffer and honour to those who undertake it. Such cases, too, as that of the creature Baker—he doesn't deserve to be called a man—who was recently convicted of sending on a long railway journey a poor little Aberdeen terrier which had been mercilessly pushed into a box utterly inadequate for its size, and with ventilation insufficient for a canary, show that there is still much nearer home to occupy the Royal Society for the Prevention of Cruelty to Animals, whose vigilance we all admire. But the last people in the world who deserve to be attacked, on the ground that they are cruel or even unsympathetic towards animals, are those devoted seekers after benefit to the human race, who are in this country, in pursuance of the objects of the Research Defence Society, conducting experiments on animals subject to strict rules and regulations and imbued with the righteous desire to cause them the least possible misery and pain.

TWO CASES OF AURICULAR FLUTTER.

BY JOHN HAY, M.D. VICT., M.R.C.P. LOND.,
SENIOR ASSISTANT PHYSICIAN, ROYAL INFIRMARY, LIVERPOOL.

IN 1908 Hertz and Goodhart [1] published a case in which there was a remarkable discrepancy between the frequency of the auricles and the ventricles. The auricles contracted at an average rate of 220 beats per minute, the ventricles infrequently, varying from 75 to 156 beats per minute. Later, in 1910, Jolly and Ritchie,[2] in reporting a somewhat similar case, applied the term "auricular flutter" to this condition, and this name has been accepted. Since then numerous cases have been reported; the most important and complete account is to be found in a paper by Lewis,[3] in which he has collected all the cases published up to that date. Since the publication of Lewis's paper, Ritchie [4] and Hume [5] have recorded further cases.

Such cases are of extreme interest and importance, but as the whole ground has recently been carefully covered by these writers, I will content myself with giving the history and tracings of two patients suffering from auricular flutter whom I have had under observation. They present certain points of interest in diagnosis, prognosis, and treatment.

CASE 1.—The patient, aged 40, was admitted to the Stanley Hospital, Liverpool, under my care on May 29th, 1906, complaining of shortness of breath, swelling of the feet and legs, and palpitation on exertion. Later he was a patient in the Liverpool Royal Infirmary in Dr. T. R. Bradshaw's ward, through whose kindness I had the opportunity of continuing my observations.

Past history.—The patient had suffered from the usual children's ailments, and had had small-pox at the age of 21 and malaria in 1900. He never suffered from rheumatism or growing pains. He had always been a heavy smoker, and until 1904 had taken alcohol in excess. He first began to notice difficulty in breathing in the early part of 1906. In April of the same year he became very œdematous and required hospital treatment. He was markedly cyanosed when admitted to the Stanley Hospital. The earliest note as to his heart was made on May 30th, 1906. The heart's action was irregular, rate 76, and the blood pressure was raised. The cardiac dulness extended 1¾ inches to the right and 5½ inches to the left of the middle line. The apex beat was not distinct, but there was a diffuse heaving in the fifth and sixth spaces in the nipple line. On listening over this diffuse impulse a distinct systolic murmur was heard, followed by a loud thumping second sound. There was a troublesome cough and evidence of fluid at the right base. Urine: specific gravity 1012, acid, no sugar, trace of albumin.

The interesting features in this case can best be followed by examining the graphic records.

Fig. 1, taken on June 11th, 1906, shows remarkably well the alternating character of the radial pulse. This was very noticeable at that time and was the chief element in the irregularity. The jugular tracing is poor, but in the light of later records we know that the small waves, *a*, are due to auricular systoles; they represent a frequency of about 240 per minute. *c* denotes movements of the lever due to the pulse in the carotid artery.

On Sept. 30th, 1907, the pulse was regular—about 70 per minute with occasional intermissions. On carefully analysing the tracing seen on Fig. 2 we find a 3 to 1 ratio. The auricles are beating 270 times per minute and the ventricles 90. The radial pulse is regular and a little more frequent than normal, and it would obviously be impossible from an ordinary examination of the patient to surmise that the auricles were beating with such great frequency. The record Fig. 2 shows an intermission; there is a long pause interrupting the regular contractions of the ventricles. There is no corresponding pause in the jugular tracing, for the waves due to auricular systole continue without variation. It was portions of the tracing such as this which led me to recognise that the cardiac condition was unusual.

Five months later a different phase was noted, as shown in Fig. 3. In this tracing the radial pulse is absolutely regular, and its rate is 60 per minute, apparently a normal action, and yet the man was not well—the reserve power of his heart was defective. In this tracing, taken on March 19th, 1908, we find the auricles acting more quietly at 240 per minute, and the ventricles responding to every fourth auricular systole, a 4 to 1 ratio. He is now under the influence of squills; this member of the digitalis group has depressed the conducting power of the junctional tissues and increased the degree of heart block, transforming the 3 to 1 to a 4 to 1 ratio. On April 9th, 1908, 20 days after the previous record showing a 4 to 1 ratio, a change was noticed: the pulse had become quite irregular and disorderly in its rhythm. The tracing Fig. 4 was taken on this date, and reveals that the auricle is now fibrillating; the very small and extremely rapid movements of the auricle are not recorded in the jugular tracing. Fibrillation of the auricle has replaced the auricular flutter. The squills has done its work.

He left hospital very much improved, and shortly afterwards obtained regular work. I met him by chance in the beginning of November, 1912, and he reported himself in excellent condition. At my request he gave me an opportunity of examining him again, and I found the heart was contracting normally. The deep cardiac dulness extended 1 inch to the right and 4 inches to the left of the middle line. The thrust of the apex beat was best felt in the sixth space, and a faint systolic murmur was audible localised to the area of the apex beat. He had no difficulty while he kept to the flat, but hills and stairs proved a burden. Fig. 5 shows the type of jugular record at this date. Note the large bifid *a* wave followed by the small *c* or carotid wave, and that the *a.c.* interval is prolonged to 4/15ths of a second. There can be no doubt that under squills the fibrillation had given place to a normal action of the heart, accompanied by a great gain in reserve power. There is still crippling, but so long as the sequence of contraction is normal he can work and earn a living.

Summary.—We have records of a man of 46 extending over a period of about seven years, demonstrating the presence of auricular flutter with a 3 to 1 ratio and occasional irregular action of the heart. When first seen alternation of the radial pulse was pronounced; this disappeared entirely while under observation. Later a 4 to 1 ratio is observed. Then in 1908 under the influence of squills the auricular flutter changed to auricular fibrillation, which in its turn gave way to a normal sequence of contraction. The heart continues to contract normally, and the patient, much improved, is earning his living.

CASE 2.—The patient, a man aged 62, was first seen in consultation with Dr. J. C. M. Given on Oct. 1st, 1912.

Past history.—For 10 years the heart had been larger than normal and occasionally irregular in its action. For the last two and a half years he had noticed that exercise produced breathlessness. That summer there had been a great increase in the liability to dyspnœa, and once or twice when golfing he felt giddy and dazed. Sometimes he experienced a sensation of fluttering behind the sternum, which he described as if there were "a bird loose in his chest." His wife had noticed for some months that when he was asleep there was a rhythmical increase and decrease in the depth of his breathing.

He was a long, thin man, and when I first saw him he was lying comfortably in bed. His general appearance was healthy, there was no œdema, and his urine was normal. The heart was much enlarged, and there was considerable heaving of the præcordium and forcible apex beat. The deep cardiac dulness extended 2 in. to the right and 6 in. to the left of the middle line. A systolic murmur was heard over the apex beat, localised and not conducted into the axilla, and a faint diastolic murmur was audible down the sternum. The systolic blood pressure for the larger beats was 170 mm. Hg; the diastolic pressure as estimated with the phonendoscope was 80–90 mm. Hg. The pulse-rate varied and averaged about 84, irregular in time and force. On Oct. 8th records were taken (Fig. 6); the radial pulse was very infrequent and almost regular in the first tracing. The remarkable feature was the presence of extremely numerous waves in the jugular veins, due to the auricular systoles. These waves became more evident in the latter half of each

diastolic pause; they were masked in the earlier portion by the free movement of the lever caused by the large carotid pulse in the neck. The auricles were beating 300 times per minute. Other records showed that some of the ventricular systoles were unable to send a palpable pulse wave to the wrist.

No further tracings were taken for a month, as he went to the South of England for a change. He returned feeling very much the better for the rest. At my suggestion while in London he saw Dr. James Mackenzie, and electrocardiograms were taken by Dr. Thomas Lewis. In Fig. 7 we have the electrocardiograms kindly taken by the latter. The elevations marked *x* indicate systolic contractions of the auricles and the larger deflections represent contractions of the ventricles. When this record was obtained the ratio was 3 to 1. The lower record in Fig. 7 was taken almost immediately after the previous records. Here we have a 4 to 1 ratio interpolated in a 3 to 1 series.

On Nov. 8th, shortly after his return, I obtained further tracings. His radial pulse was regular, with a very occasional intermission. He was much improved; the breathing was much easier, the cardiac reserve was greater, and he experienced no discomfort on easy walking. Pulse 80 to 84 per minute. Blood pressure 140 mm. Hg systolic, 100 mm. Hg diastolic. A 3 to 1 ratio was present, the frequency of the auricle being 261, ventricles 87. (Fig. 8.) Occasionally a longer pause ensued, and instead of the ventricles responding to every third systole of the auricles the ratio is 6 to 1, followed by a 4 to 1, and then the 3 to 1 ratio is resumed. Note in this tracing the significant alternation in the pulse. It was decided to give digitalis in large doses, and he was accordingly ordered the B.P. tincture, 40 minims daily. On Nov. 26th, after he had taken 290 minims, I took another tracing. (See Fig. 9.) The ventricles were beating comparatively regularly while the record was being taken, but after walking about their frequency was increased and the rhythm became less regular.

Note that the auricles are still contracting at the rate of 260 per minute, the ventricles about 31 per minute. A condition of complete block has been induced by full dosing with digitalis. The auricular waves *a* are excellently seen in the jugular pulse. When the ventricles were contracting at this funereal pace the patient experienced an unpleasant sensation of tugging with each heart-beat. The digitalis was continued until he had taken in all 360 minims; then as the ventricles continued to contract at 30 and there were no signs of the auricular flutter giving way to auricular fibrillation as the first step to the resumption of a normal rhythm, we stopped the continued administration of the digitalis, and since then have only allowed sufficient to act as a restraining influence and prevent undue frequency of the ventricles. On Dec. 1st, 1912 (when in bed), records showed the peculiar coupling of ventricular systoles which one sees so frequently in cases of Stokes-Adams disease or auricular fibrillation under the influence of digitalis. (Fig. 10.) The pulse-rate was then very infrequent.

It was of interest to note that at times the radial pulse showed a superficial resemblance to that of the disorderly rhythm of auricular fibrillation. (Fig. 11). Towards the end of January it was quite impossible to obtain any record of the jugular pulse. Careful examination of the sphygmograms, using the method of spacing described by Lewis, at once reveals that these are the records from a patient in whom the auricles are in a condition of flutter. For example, in Fig. 11 the space *a* exactly coincides with the space *b*, and so on. At the time these records were taken the patient was feeling much better and looked remarkably well. He felt that his cardiac reserve was much improved. The pulse varied considerably in frequency and regularity. To a casual observer feeling it for the first time it would give the impression at one time of intermissions due to occasional extrasystoles, at another of the irregularity due to auricular fibrillation. The blood pressure was 160 mm. Hg systolic, and 100 mm. Hg diastolic. At this time he was taking 10 minims of the official tincture of digitalis each night, which amount was just sufficient to steady the action of the heart, but not enough to cause undue slowing of the ventricle such as was present on Nov. 26th. (Fig. 9.) It is of interest to note that the slight tendency to Cheyne-Stokes respiration quite disappeared, and that there is now no evidence of alternation in the pulse, such as we see in the tracing taken on Nov. 8th. (Fig. 8.) In spite of the abnormal frequency of the auricular systole he feels well, transacts a certain amount of business three mornings a week, and enters into ordinary social life.

Summary.—A man aged 62 came under observation with a large heart and peculiar arrhythmia. For 10 years the heart has been known to be increased in size, and occasionally irregular in its action. The auricular rate was 300; the ventricular 50 to 60, and coupled. A month later a 3 to 1 rhythm was present—auricular rate 261, ventricular rate 87. Cheyne-Stokes respiration and alternation of the pulse were noted. Large doses of digitalis produced a high grade of heart-block, but the auricular flutter persisted and is still present. The general condition of the patient is much improved. A small dose of digitalis daily is required to moderate the frequency of the ventricle.

Note.—On April 17th I took polygraph records. These demonstrate that the "flutter" has ceased and that the heart is again acting normally with the exception of numerous extrasystoles originating in the auricle.

Liverpool.

HEMIPLEGIA FOLLOWING SYPHILIS,

WITH SPECIAL REFERENCE TO A CASE OF DOUBLE HEMIPLEGIA AND PSEUDO-BULBAR PARALYSIS.

BY MURDOCH MACKINNON, M.D. EDIN., D.P.H. OXON.,

CASUALTY PHYSICIAN TO ST. MARY'S HOSPITAL, LONDON; LATE MEDICAL SUPERINTENDENT AND REGISTRAR, SEAMEN'S HOSPITAL, GREENWICH.

SYPHILIS as it affects the nervous system was formerly considered to be a late secondary or tertiary manifestation of the disease, and the symptoms and signs of cerebral syphilis were calculated to become manifest usually between the third and tenth year after the primary infection. It is now recognised, however, that brain syphilis may occur much earlier than this, and recent statistics show that about half the lesions occur within the first two years of the primary infection and the remainder are distributed over the next 12 years. According to Mott half of the lesions occur within the first four years. One of the commonest results of cerebral syphilis is hemiplegia, and although the period of its maximum frequency is between the third and tenth year, cases occur within the first year, and even within the first few months instances have been reported. The rarity of the latter, however, is well known, and the notes of the following cases, more especially of the first case, are interesting in that they show how early after the primary infection intracranial lesions may occur, and also the multiplicity of the lesions which is so characteristic of the disease, and serves to differentiate it from similar symptoms occurring in non-syphilitic cases.

CASE 1.—A Chinese sailor, aged 39, was admitted to the Hospital for Seamen, Greenwich, on May 3rd, 1910, with a healing chancre on the penis and a roseolar rash on the forehead, shoulders, and elbows. He denied having run any risks of being infected with syphilis, but from the nature of the sore on the penis and the condition of the rest of the body there was no doubt whatever, as subsequent events proved, that the patient was suffering from the primary effects of the syphilitic virus. The treatment adopted was the injection of benzoate of mercury, ½ gr. daily, and the administration of potassium iodide, 10 gr., three times a day. He had about 16 injections altogether, and in about three weeks time all external manifestations of the disease had disappeared, and he was able to leave the hospital on August 10th apparently quite well. He was given instructions to continue taking mercury pills, a prescription for which was supplied him. On Sept. 30th, however, he was readmitted with a history of having lost the power of his right arm and leg four days previous to admission. He had slept quite well the night before, but on waking in the morning he noticed that he could not move the right arm and leg and was unable to open the left eye. On examination of the patient the following brief notes were taken:—"Drooping of the left eyelid, patient cannot raise it. There is no intraocular paralysis, and pupils are equal and normal in reaction to light and accommodation. Right corner of the mouth droops, and facial line is less distinct than on the left side. Tongue is protruded to the right. Right arm: Loss of power in the arm, but not absolutely paralysed. Hand grip very weak. There is no loss of sensation. Right leg: Paresis as in right arm. Knee-jerks increased. Babinski's toe reflex. No sensory changes. Left side: No paresis or sensory changes. Reflex normal. Chest: Healthy. No cardiac lesions." On Oct. 10th there was a good deal of improvement in the condition of the left eye and the right arm. He could now open the eye a little, and the hand grip was much stronger. On the 15th he was continuing to improve. Slight paresis was still present, but power was returning to the limbs. On the 25th he could open the left eye. On Nov. 1st the gums

were sore. The mercury was stopped for a time, and he was given potassium iodide. On Dec. 19th he was discharged much improved. He could open the eye quite well now, and could use the right arm and leg almost as well as the left. He was given a mixture of biniodide of mercury, which he was to continue taking. On Jan. 2nd, 1911—that is two weeks after his discharge and three months after the appearance of right hemiplegia—the patient was again admitted to the hospital, but this time with a complete left hemiplegia and inability to talk. He was quite unable to speak, but from signs in answer to questions it appeared that the attack came on as before, during sleep, and on waking in the morning he found he could not move the left side at all and was unable to talk. There was complete paralysis of the tongue, soft palate, and lips. He could not protrude his tongue or move it to either side. The soft palate did not move and there was great difficulty in swallowing, especially liquids. Breathing was difficult and apparently was effected with great effort. Left arm: Marked loss of power. Could move fingers and wrist slightly. No loss of sensation. Left leg: Could raise the leg a little, but it was much weaker than the right. Babinski's toe reflex. Knee-jerks increased. No ankle clonus. Right arm: Fairly strong, but obviously weaker than normal. Biceps, triceps, and supinator jerks increased. Right leg: Fairly strong, but knee-jerks increased. Babinski's toe reflex. Ankle clonus. Sphincters unaffected. Jan. 15th: Patient improving slightly. Taking mercury and potassium iodide. He could swallow a little better, but was still unable to speak or protrude the tongue. The left arm was much stronger. Feb. 1st: General condition much improved. Could move the tongue slightly, but could not protrude it beyond the teeth. The left arm and leg were much stronger. On the 11th an injection of salvarsan ("606") 0·6 grm. was given. On the 18th he could talk a little and could protrude the tongue beyond the lips and swallow fluids and solids with comparative ease. The patient continued to make steady improvement and before his discharge on June 16th could walk and talk perfectly well, and beyond a slight exaggeration of reflexes on both sides and a little stiffness in walking there were no signs left of the successive attacks of paralysis.

In addition to the above case three others have come under my notice, all showing hemiplegic paralysis on one or other side, occurring at varying periods after the primary sore, but all of them undoubtedly secondary to the syphilitic infection.

CASE 2.—The patient, aged 30, was admitted to the hospital with loss of power in the right arm and leg. Nine months previously he had contracted syphilis, for which he was treated at this hospital for three and a half months. He was then discharged, continuing the treatment as before. Fourteen days before his admission he woke up in the morning with paralysis of the right arm and leg. There had been no premonitory symptoms. Physical signs: Divergence of tongue to affected side and facial paralysis. Paresis was never sufficient to inhibit progression, and under appropriate antisyphilitic treatment the patient rapidly improved. There was no cardiac disease or any evidence of arterio-sclerosis. Six weeks previous to this he had ptosis of the right eye. He states that previously to that he had paralysis of the left eye, from which he recovered.

CASE 3.—The patient, aged 40, was admitted to the hospital in December, 1909, suffering from paralysis of the right leg. It was elicited that in September, 1907, he had found that he could not open his right eye in the morning. There was no pain. For four months he was unable to open the eye completely. After that the condition slowly improved. He had been treated as an out-patient. In January, 1908, he had sailed to Cape Town, and while there was seized with sudden pain in the right leg with loss of power. He did not fall, and was able to walk to the hospital. From there he was sent home, and had since been taking medicine. In September, 1908, he had a transient attack of aphasia which lasted a few days and then cleared up. He had had a chancre; was uncertain as to date, but thought it was in 1903. On admission the patient was found to be a rather stout, robust man. There was no paralysis of the tongue, and the palate moved well. Eye: No diplopia. Right pupil slightly larger than left. Does not act so well. No ptosis. Slight weakness of right orbicularis palpebrarum. No facial paralysis. Arms: No tremor. Coördination perfect. Elbow- and wrist-jerks increased, especially right. Sensations normal. Right leg much weaker than left. Slight foot drop. Pigmentation of skin. Knee-jerk exaggerated. Ankle clonus. Plantar reflex, extensor.

CASE 4.—The patient, aged 30, was admitted to hospital on Dec. 21st, 1910, with loss of power in the right arm and leg. He had contracted syphilis nine months before admission, and had been treated for three and a half months as an in-patient and since then privately. Fourteen days before admission he lost the power of the right side during sleep. He had gone to bed quite well the night before, and there were no premonitory symptoms. The paralysis was not complete, as he was able to walk about fairly well, although very much weaker on that side. On admission the patient was found to be a well-nourished man. There was paresis of the right arm and leg. Facial folds flattened on the right, and the tongue was protruded towards the right side. The patellar reflex was much exaggerated on the right side, and ankle clonus was present. There was no ocular paralysis. There were no sensory changes. The patient was given a mixture of mercury and iodide of potassium three times a day and made rapid improvement. He was kept under treatment for six weeks, and on his discharge was perfectly well, having regained complete power of his limbs.

Hemiplegia due to syphilis, although as a rule presenting physical signs similar to those arising from hemiplegia due to other causes, at the same time differs in certain characteristics, and the first case narrated in this paper is typical in that respect. The brief notes of the cases which follow agree in the main with the above in respect to age, mode of onset, and termination, the succession of symptoms indicating multiple lesions and the complete recovery under suitable treatment

With regard to the etiology of syphilitic hemiplegia, it is well known that the vascular lesion, which is the commonest cause of this condition, is the obliterating endarteritis, a condition which may be found in a number of smaller arteries throughout the body, but most frequently in the smaller terminal arteries of the brain. The pathological change affecting the vessel walls begins as a proliferation of the adventitia. The increase of newly formed fibrous tissue frequently tends to the formation of a thrombus in the contracted lumen of the vessel, and according as to whether the thrombus partially or completely obliterates the lumen of the terminal artery the result is a hemiparesis or a complete hemiplegia. There may be a condition of unilateral numbness and tingling during the stage of partial obliteration due to the ischæmia of the part of the brain supplied by the obliterated vessel, and this condition may precede for several hours, or even days, the onset of sudden paralysis. This paralysis may readily be recovered from if the case is seen and diagnosed sufficiently early to allow of the appropriate antisyphilitic remedies being freely administered. Fortunately this is the result of treatment in most cases, but in a few the paralysis is permanent, on account of delay in treatment and the degeneration and softening of that part of the nervous system deprived of its blood supply. These vascular lesions are described as the early tertiary or late secondary manifestations of syphilis.

SYPHILIS: ITS DANGERS TO THE COMMUNITY, AND THE QUESTION OF STATE CONTROL.*

BY H. C. FRENCH, M.R.C.S. ENG., L.R.C.P. LOND.,
MAJOR, ROYAL ARMY MEDICAL CORPS.

(*Concluded from p. 917.*)

Resolutions adopted by the International Congress on the Prevention of Syphilis and Venereal Diseases; Brussels, September, 1899.

1. That the Government should use their utmost powers to suppress the prostitution of girls under age. 2. That a permanent international "Society of Social and Moral Prophylaxis" should be constituted, having its headquarters in Brussels, issuing a quarterly journal in French, English, and German, and holding congresses from time to time; the first congress to meet in Brussels in 1902. 3. That since a thorough knowledge (*connaissance approfondie*) of venereology is one of the most important means of effectually combating the spread of disease, complete and compulsory courses of instruction in the subject for all medical students should be instituted in every University, so as to ensure the training of really competent practitioners. 4. That guardians of orphans, and others charged with the education of the young, should use every effort to promote their moral development, and to teach them temperance and respect for women of all classes.[4] 5. That the utmost rigour of the law should be enforced against *souteneurs*.[5] 6. That the Governments should appoint in each country a commission charged to ascertain the amount of these diseases, apart from temporary fluctuations, among the *civil* population; to inquire into the existing means of treatment, the distribution of hospitals in various localities, &c., and to collect opinions and formulate proposals as to the best means of preventing the dissemination of the malady.[6] 7. That the Governments should find means to warn the public, and especially young persons, of the dangers attending an immoral life. 8. That the statistics of disease should be drawn up in all countries on a common basis. All these resolutions were passed unanimously.

* A report presented at a joint session of the sections of Dermatology and Syphilography and of Forensic Medicine at the Seventeenth International Congress of Medicine, London, 1913.

[4] This was brought by a Russian delegate, Dr. de Sturmer, from a Russian Medical Congress, where it had been unanimously adopted.

[5] I.e., men who live upon the earnings of prostitutes.

[6] Proposed by Dr. Saundby on behalf of the British Medical Association.

Conclusions.

None of the final resolutions touched upon the question of State regulation at all. It was felt that if the Conference was to speak with authority it must speak "unanimously," and on this subject it was evident that opinions were hopelessly divided. Four of the resolutions aim at the "prevention of vice" as the root of the whole evil, while the remainder seek to increase the efficiency and accessibility of medical aid, to apply a "stimulus to research," and to bring all results into the common treasury. There is no reason to fear the light if only there is light enough.

We desire to rebut a common error and a not infrequent misstatement. M. Pierson, president of the International Society for the Abolition of Regulation, stated at the International Conference at Brussels, 1899, "that men infected with venereal disease were as dangerous as women, as they were not subject to regulation." This statement is erroneous for two reasons. First, a woman practising prostitution as a trade usually associates with numerous men. A man does not, and could not, associate with a like number of women. Secondly, a woman does not, as a rule, know that she is suffering from venereal disease, since she cannot see, and rarely feels any discomfort. She consequently spreads a large amount of disease in ignorance, and would not come under treatment unless she were medically inspected. A man, on the other hand, both knows, sees, and suffers from his venereal complaints, and usually seeks early advice. The European public prostitute, in her own interest, is necessarily only too ready to be cured when she knows she is diseased. This she cannot ascertain until others discover it. The clandestine prostitute, however, whether European or native, would never willingly undergo treatment even when she knows she is diseased. She practises her trade secretly, is not under any effectual control, and spreads ten times as much disease as a public prostitute. Such is the case in European countries, and it is endorsed by Indian experience. In speaking of the direct conveyance of acquired syphilis, gonorrhœa, and soft chancres (non-infecting sores), the amount of disease conveyed by a woman is, for the foregoing reasons, probably one hundred times as much as that conveyed by a man. This is important to remember in regard to the administrative control of venereal diseases, and a point that we have rarely seen sufficiently recognised.

Professor Fournier (Paris) said, "Statistics are good when they support you, and bad otherwise." When inaccurately collected it must be admitted that statistical evidence is most unsatisfactory and very conflicting. For the statistics of venereal disease to be really valuable they must be the result of personal inquiry, personally collected, the deductions fairly drawn and based on a sound system. In fact, if statistics are to prove anything they must be much more carefully revised and systematised. We indicate in what manner later on, in the scheme propounded for the army in the year 1904.

Prolonged treatment is only necessary in the case of syphilis. Non-infecting chancres (soft chancres) are seven to ten times as frequent as infecting chancres (primary syphilitic chancres, indurated chancre) in the case of soldiers in the British Army. This is probably the case as regards relative incidence amongst women. One or two months' adequate treatment and isolation would effectually cure nine-tenths of persons infected with venereal disease. In this category we include gonorrhœa for the purpose of isolation. Quite a small number of persons are infected otherwise than by "direct contact" with local lesions on the pudenda. The cure of these lesions is ordinarily quite an easy and a feasible task. Free prostitution undoubtedly means unrestricted syphilisation of the people. A syphilitic woman is a real source of danger, but any method of dealing with this question could only be successful by the early isolation of infected men and women, and by the efficient inspection of *both*.

It was further represented at the Conference in 1899 at Brussels that: "The criminal phases of prostitution should be under the jurisdiction of the criminal courts, and not, as at present, subject to the will of the police authorities and the regulations concerning surveillance. Under the present system much that is prohibited by criminal law is permitted by the police code."

Efficiency of control necessarily depends on the "competence of individual physicians." Unregistered prostitutes, however, came to dispensaries in a frightful state. It was conclusively shown that syphilis amongst women in Europe was most common between the ages of 17 and 22. The same applies to India. Prostitutes in Christiania, suffering from syphilis, who are arrested for other offences, did not come under treatment. Professor Peterson said that regulations worked well in Russia, and that supervision and inspection are of the greatest importance in preventing the spread of syphilis. It was generally admitted that medical inspection was "not as good as it might be." Many persons urged that it would be better to make inspection altogether a medical matter and to coördinate it with treatment by letting the women attend at special dispensaries. (This is done in India and with excellent results.) (Vide Appendices B and C and Tables III. and IV.).

Mr. C. F. Marshall[7] states: "Patients prefer to go to general hospitals or to skin hospitals, where they are treated as ordinary hospital patients and not as criminals and outcasts. ..... This state of things results in the almost entire neglect of the study of venereal and syphilitic diseases in this country. On the Continent, and in America, these diseases are recognised and studied in the same way as other diseases, and are not covered with the hypocritical cloak of British prurity." Mr. Brasher writes on May 29th, 1893: "A brief reflection will show that a large number of syphilitic patients would on no account voluntarily enter a lock hospital." He ventures to suggest that an important factor in the control of syphilis is to obtain greater "uniformity of treatment." "Greater uniformity of treatment and 'education of the public' on this subject will lessen, but not prevent, the recurrence of syphilis; more than this is needed. The fact that syphilis is an 'acute specific' points to notification under the Infectious Diseases (Notification) Act as the only logical course." It may be objected that notification will result in concealment, recourse to quacks, and inability of sanitary authorities to punish offenders. To this it may be replied that the success of the present notification is due to the public's recognition of the Act as a powerful preventive of the spread of disease, and therefore worthy of implicit obedience. "Undoubtedly the prolonged course of syphilis and the impossibility of keeping patients under constant observation are difficulties, but if the public can be educated as regards tuberculosis, they may also be taught that syphilis is as terrible a disease, and that it is also a preventable one."

Let us consider how the foregoing principles are supported by personal experience at Malta in the past three years. The enormous reduction in syphilis effected in recent years amongst soldiers in Malta has mainly resulted from the more thorough control of venereal diseases at their source in the civil community, which has enormously benefited. This has been effected by means of a system of "confidential medical notification" and more effectual segregation of diseased persons, commencing in October, 1909, and applied equally to both sexes. A Government Ordinance has existed in Malta since 1861, and this was amended in 1898, to make it in effect a sanitary ordinance on the lines of the Indian Cantonment Act of October, 1897 (*vide* Appendix B and Tables III., IV., V.).

Amongst troops in Malta, in 1908, syphilis caused 18·6 admissions and 2·33 constantly sick in hospital per 1000. This was not high, but it has been reduced to one-fourth in 1911—namely, 4·3 admissions and 0·42 constantly sick per 1000, and no invalids for syphilis, gonorrhœa, or soft chancre. This result occurred in a garrison of 7000 soldiers amongst a civil population numbering nearly a quarter of a million of persons, and a fleet of 7000 strong arriving periodically. Not only was the incidence of freshly contracted disease lessened, but all forms of disease, syphilis, soft chancre, and gonorrhœa, were also attenuated. Table II. gives the actual number of soldiers on the Syphilis Register and the actual number of cases contracted in Malta, with such medical notification in force during my tenure of appointment since September, 1909, as contrasted with the admission and the constantly sick daily in hospital ratios. It can be observed that in 1910–11 there is a progressive reduction both in the incidence of syphilis contracted in Malta as well as in the admission and constantly sick ratios. The two latter, though partly dependent on the incidence of freshly contracted disease, are more largely influenced by administrative measures plus medical treatment, the sum total being largely

[7] Brit. Med. Jour., May 23rd, 1899.

dependent on the lubricating oil of individual initiative, on the introduction of measures to meet the frequently changing exigencies of local requirements, and on systematised procedure and centralisation of work.

The naval and civil authorities also report the marked reduction of disease; and provided that the immigration of diseased persons from ouside areas can be controlled, poverty and its twin sister, disease, will eventually be lessened by a reduction in the cost of maintenance of poor-houses, prisons, and lunatic asylums (in which places syphilis is domiciled), and the illegitimate birth-rate lessened. What has been done in the island of Malta can be equally done in the British Isles—with effort.

In Malta several other factors have also contributed to good results, and in the case of syphilis they have been obtained with mercury, potassium iodide, and local treatment. The results under mercury endorse those obtained at Woolwich (Table I.) in 1905–9, and endorse Indian experience (Table III.). The marked reduction in syphilis from 1909 to 1911 in Malta, in India 1898 to 1910, and throughout the army generally as exemplified by these tables, occurred before the introduction of salvarsan. A "Syphilitic Record Book," introduced in 1904, and modified in 1910, exists in each station, and the particulars from the "syphilis case-sheet" are entered for permanent reference. These general principles have recently been applied to gonorhœa, and a "gonorrhœa case-sheet" as an official army form is now in use. Finally, by means of a "venereal surveillance form," cases are followed up on discharge from hospital or on transfer to other stations.

It may prove of interest to trace the origin of methods which, in a modified degree or in a different manner, could be easily made applicable to the control of venereal diseases in civil communities. In July, 1903, I applied to the War Office for permission to publish some printed matter, the results of investigations in India from 1896 to 1901, and previously, on the control of venereal diseases in the Army. The absolute necessity of entirely revising the collection of venereal statistics, systematic case-taking, and accurate diagnosis was emphasised. Up to this date all cases of venereal sores, whether soft chancre or early primary syphilis, were indiscriminately recorded as primary syphilis or primary venereal sores. If secondary syphilis followed, then a change to secondary syphilis was made if the case happened to be in hospital. This was confusing and misleading. In September, 1903, therefore, a preliminary tentative scheme was brought into force—"Instructions regarding Procedure in Cases of Syphilis." Under this scheme syphilis and soft chancre became absolutely differentiated. From Jan. 1st, 1904, the scheme was made universal throughout the whole army at home and abroad, and was later incorporated into Appendix VII., Regulations Army Medical Services. Under this scheme all venereal sore cases after discharge from hospital are now kept under weekly observation, according to time spent in hospital, for two or four months before the diagnosis of soft chancre, or syphilis, is finally made. This is very important in limiting the local spread of disease arising from relapsed chancres, or a recrudescence of disease. Latterly, I have kept gonorrhœa cases under weekly observation for six weeks from date of discharge from hospital, with excellent results in lessening disease both in the case of the soldier and the local civil community.

If, therefore, the legislature in this country is later guided by our deliberations, the administrative system of control existing in the army can easily be adopted or improved on to meet the special requirements of civil communities in England. It is first necessary, however, to get legal control of syphilis in a manner that small-pox and other much less dangerous diseases are controlled. It is absolutely essential, from a public health point of view, to go to the legislature of the country with concrete proposals and undivided counsels.

In summarising the means at our disposal it is requisite to bear in mind that there are three main principles involved in the prevention and control of venereal diseases. First, control at the source which is concerned with prostitution before disease is contracted or spread. This embraces (*a*) medical notification of disease; (*b*) suppression of *souteneurs* and solicitation in the streets; (*c*) protection of orphans and destitute children; (*d*) police measures. Secondly, prevention by medical measures—i.e., prophylaxis by treatment after disease has been contracted. This includes: (*a*) provision of hospital beds and segregation; (*b*) professorships at large hospitals; (*c*) instruction of students and the public; (*d*) treatment. Thirdly, moral and religious considerations. These are placed last, but are by no means least, and are more applicable to youth and adolescence before disease is contracted. At the Brussels International Conference in 1899 the consensus of medical evidence was distinctly in favour of revised regulations for dealing with prostitution apart from the State control of vice (vide Appendix A). The abolitionists of regulation strongly advocated the *notification* of venereal diseases, female inspectors of factories, and reformatories for young girls aged under 21 who adopt a vicious life, where they could be taught a trade and be reclaimed.

If we recognise the cardinal fact that prostitution has always existed, and unfortunately must continue to do so for all time—since, as previously explained, it is largely dependent on poverty—it then becomes self-evident that to control disease which is the direct outcome of uncontrolled prostitution it becomes necessary to first effectually control all persons who practise it. This is the really important consideration as regards the community. The individual aspect in the interests of public health must be sacrificed to the general principles which govern our action. In law the individual aspect is frequently sacrificed to the general issues. This principle is rightly recognised and its utility is obvious. In public health questions, however, we yearly sacrifice thousands of lives and destroy a carefully constructed social fabric at every turn, because we do not recognise an elementary truth, or in recognising it fail to act. In the absence of the fulfilment of an impossible ideal such as the entire suppresion of prostitution, it is necessary to control its undue exercise by effectually preventing open solicitation in the streets, as in London, and limit prostitution by localising it. This is a police matter. Clandestine prostitution must be absolutely suppressed with a firm hand. To do this we must legally deal with the procurers of it, who are numerous, and with the incentives to it, which are many. Until public opinion is better informed it is hopeless to expect that any real progress will be made, our prisons will be full of prostitute women, as at present, and lunacy will continue to increase.

In conclusion, I quote from Mr. Lecky's History of Morals[a]: He deplores the fact "that an epidemic, which is one of the most dreadful now existing amongst mankind, which communicates itself from the guilty husband to the innocent wife, and even transmits its taint to her offspring, should be suffered to rage unchecked because the legislature refuses to take official cognisance of its existence, or proper sanitary measures for its repression."

APPENDIX A.—*Foreign Countries.*

In regard to systems of regulation of prostitution in foreign countries: At the International Meeting at Brussels in 1899 the question before the meeting was: Have the systems of regulation actually in force had any influence upon the frequency and dissemination of syphilis and venereal disease?

Dr. Barthelemy, one of the medical chiefs at St. Lazare Hospital, Paris, said: "It was impossible to apply inspection properly without registration. Free prostitution meant unrestricted syphilisation of the people." He denied "that registration made women professional prostitutes, as they were so before. Disease was due to immorality, not to regulation; passion was an eternal and imperative factor in human life, and regulation was a means of combating its attendant evils. If it had not yet succeeded, that was not a reason for abolishing but for improving it." He recommended "gentler" methods.

I understand that the old prison hospital at St. Lazare, Paris, is to go, and a hospital to be built for diseased prostitutes.

Professor Fournier "would not trust to statistics, but appealed to common sense. An infected prostitute was safe only when she was shut up." He stated that the opponents of regulation (abolitionists) minimised the appalling deformities and dangers of syphilis. Professor Lassar (Berlin) agreed with Professor Fournier, and considered "that an infected prostitute was a focus of disease which it was the duty of society to remove." Professor Neisser (Breslau) shared Professor Fournier's opinions and was opposed to the views of the abolitionists.

The Italian doctors drew attention to the very serious increase of disease in Italy on the abolition of Cavour's system by Signor Crispi in 1888. The same thing occurred in India in 1885, when 15 of the principal hospitals were closed as an experiment. The experiment being unsuccessful, the hospitals were reopened until 1888, and then closed until 1897. During this period the increase of disease was appalling. Control again began in October, 1897 (vide Tables III. and V.). Dr. Bortavelli (Milan) supported regulation. Professor Oltramana (Geneva) said that the question had lately been put to the vote in Geneva and regulation affirmed by a majority of two to one. He considered "that the success of regulation depended greatly upon the competence and carefulness of the physicians to whom the work was entrusted."

[a] Vol. ii., pp. 280 et seq.

Professor Holst (Christiania) said that since the abolition of regulation in Christiania syphilis had increased 25 per cent. and clandestine prostitution had increased. Professor Sturmer (St. Petersburg) supported regulation, and said "that unregistered prostitutes came to the dispensaries in a frightful state." Professor Peterson said that regulation worked well in Russia, and moved "that supervision and inspection are of the greatest importance in preventing the spread of syphilis."

To reduce the number of prostitutes the abolitionists of regulation at the International Conference at Brussels in 1899 directed their efforts against immoral literature, alcohol, dancing-rooms, and the stage. They recommended the increased care of neglected children, the provision of female inspectors of factories, more employment for women, and the notification of venereal disease.

Dr. Jullien (Paris) produced tables to prove that venereal disease occurred more commonly amongst unregistered prostitutes, and that syphilis was most common in women between the ages of 17 and 22. The age of women is an important factor in contagion. Dr. Blaschko (Berlin) pointed out "that the unregistered women were the younger women, who were always the most dangerous. It was not regulation that rendered the courtesan less dangerous; it was time." Dr. Sperck, the great Russian specialist, found "that the amount of syphilis conveyed by the registered women was proportionate to the recruitment of their ranks by healthy women. These were soon infected themselves."

There was a strong consensus of opinion "that instead of placing the whole trade of prostitution under police control they would put the entire administration on a purely medical footing and make the inspection itself an appendage and continuation of the hospital treatment. The action of police should only be admitted where patients failed to continue their attendance, or in the case of women denounced as centres of infection. The work of examination should be in the hands of venereal specialists. Early and effectual treatment was the goal to be aimed at. Two things are therefore essential—namely, improved medical education, to ensure a supply of competent doctors, and diffused information, that is, protection by knowledge."

APPENDIX B.—*The Cantonment Code, 1899, India: In force October, 1897.*

Par. 175. No public prostitute shall be permitted to reside within the limits of any regimental bazaar situate in the cantonment.

Par. 209. Whoever, in any street or public place in the cantonment, loiters for the purpose of prostitution or importunes any person to the commission of sexual immorality shall be punishable with imprisonment for a term which may extend to eight days, or with fine which may extend to fifty rupees, provided that no person shall be charged with a breach of the provisions of this section except on the complaint of the person importuned or of an officer as defined in the Cantonments Act, 1899, in whose presence the breach was committed, or of a member of the British military police force employed in the cantonment and specially authorised in this behalf by the commanding officer of the cantonment in whose presence the breach was committed.

Par. 174. The cantonment authority may by notice in writing prohibit (*a*) the keeping of a brothel or (*b*) the residence of a public prostitute in the cantonment or any specified part thereof.

Par. 86. The cantonment authority may attach to the outside of any building brackets for lamps.

Par. 87. The cantonment authority may cause a name to be given to any street and a number to be affixed to any building.

Par. 196. (1) So far as the funds at its disposal permit, the cantonment authority may provide and maintain, either (*a*) within or without the cantonment, as many hospitals or dispensaries as may be necessary; or (*b*) make upon such terms as it thinks fit to impose a grant in aid to any hospital or dispensary, whether within or without the cantonment not maintained by it. (2) Every hospital or dispensary maintained or aided under subsection (1) shall have attached to it a ward or wards for the treatment of persons suffering from infectious or contagious disorders. In this section the expression "infectious or contagious disorder" includes venereal disease.

Par. 201. At every hospital or dispensary maintained or aided under Section 196 the sick poor of the cantonment, persons in the cantonment suffering from infectious or contagious disorders, and with the sanction of the cantonment authority any other sick persons may receive medical treatment free of cost, and, if treated as in-patients, shall be either dieted gratuitously, or, should the medical officer in charge so direct, granted subsistence on a scale to be determined by the cantonment authority. Provided that the subsistence allowance granted as aforesaid shall not be less than the lowest allowance for the time being fixed for the subsistence of judgment-debtors by the Local Government under Section 338 of the Code of Civil Procedure. In this section the expression "infectious or contagious disorder" includes venereal disease.

Par. 203. If the medical officer in charge of a hospital or dispensary maintained or aided under Section 196 has *prima facie* grounds for believing that any person living in the cantonment is suffering from an infectious or contagious disorder, he may by notice in writing in the form set forth in Schedule II. or in any similar form call upon such persons to attend at the hospital or dispensary at a time to be specified in the notice, and not to quit it without the permission of the medical officer in charge unless and until such medical officer is satisfied by examination (if necessary) that such person is not, in fact, suffering or is no longer suffering from such disorder. Provided that if, having regard to the nature of the disorder or the condition of the person suffering therefrom or the general environment and the circumstances of such person, the medical officer considers the attendance of such person at the hospital or dispensary inexpedient he may dispense with such attendance and take such measures or give such directions as he may think fit and proper. In this section the expression "infectious or contagious disorder" includes venereal disease.

Par. 204. If the medical officer in charge of a hospital or dispensary maintained or aided under Section 196 reports in writing to the commanding officer of the cantonment that any person, having received a notice as provided by Section 203, has refused or omitted to attend at the hospital or dispensary, or that the person having attended at the hospital or dispensary has quitted it without the permission of such medical officer; the commanding officer of the cantonment may, if he thinks fit, by order in writing, direct such person to remove from the cantonment within 24 hours, and prohibit her from remaining longer in or re-entering it without his permission in writing.

Par. 177. Whoever—(*a*) being a medical practitioner and in the course of practice becoming cognisant of the existence of an infectious or contagious disorder in any dwelling, other than a public hospital or dispensary, in the cantonment or its neighbourhood, or (*b*) in default of such medical practitioner, being the owner or occupier of such dwelling and being cognisant of the existence of any infectious or contagious disorder therein, or (*c*) in default of such owner or occupier, being the person in charge of, or in attendance on, any person suffering from any infectious or contagious disorder in such dwelling and being cognisant of the existence of the disorder therein; fails to give information or gives false information to the cantonment authority respecting the existence of such disorder, shall be punishable with fine which may extend to 50 rupees. Provided that a person is not required by this section to give information in the first instance, but only in default of some other person, shall not be punishable if it is shown that he had reasonable cause to suppose that the information had been or would be duly given. Provided also that this section shall not apply to venereal disease where the person suffering therefrom is under specific and adequate medical treatment and, by reason of habits, conditions of life and residence, is unlikely to spread the disease. In this section the expression "infectious or contagious disorder" includes venereal disease.

Par. 105. Every keeper of a Sarai shall be bound to make an immediate report, to the officer in charge of the police station, of any person ill with an infectious or contagious disorder.

Par. 207. (1) The cantonment authority may provide or prescribe suitable routes for the use of persons passing through the cantonment (*a*) on their way to or from fairs or places of pilgrimage or other places of public resort; or (*b*) during times when an infectious or contagious disorder is prevalent, and may by public notice require such persons as aforesaid to use such routes and no others. (2) All routes provided or prescribed under Subsection (1) shall be clearly and sufficiently indicated by the cantonment authority.

Par. 178. (1) In the event of the cantonment being at any time visited or threatened by an outbreak of any infectious or contagious disorder among the inhabitants thereof, or of any epidemic disease among the cattle, sheep, or goats therein, the general officer of the command, if he thinks that the provisions of this or of any law at the time in force are insufficient for the purpose, may, with the previous sanction of the Local Government, (*a*) take such special measures, and (*b*) by public notice, prescribe such temporary regulations to be observed by the public, or by any person or class of persons, as he thinks necessary to prevent the outbreak of the disorder or disease or the spread thereof. (2) Whoever commits a breach of any temporary regulation prescribed under Subsection (1) shall be deemed to have committed an offence punishable under Section 188 of the Indian Penal Code.

Par. 208. No mendicant shall in any street or public place in the cantonment loiter or beg for alms.

Par. 210. The cantonment magistrate may on receiving information that any person whether resident in or frequenting the cantonment "is a disorderly person keeping or frequenting a disorderly house of any description" may prohibit such person from residing in or re-entering a cantonment, after reporting the matter to the officer commanding the station.

Par. 211. The officer commanding the station, if he thinks it expedient, and with or without assigning any reason therefor, may exclude any person from cantonments. Provided that the officer commanding the cantonment thinks that the presence of the person in the cantonment is dangerous to good order and military discipline.

Par. 212. Whoever harbours or conceals a person prohibited from entering the cantonment shall be punishable with imprisonment which may extend to eight days, or with fine which may extend to 50 rupees.

Par. 204. (2) Whoever, having been prohibited from remaining or re-entering the cantonment, fails to remove from or re-enters it without the permission in writing of the commanding officer of the cantonment, shall be punishable with imprisonment for a term which may extend to eight days, or with fine which may extend to 50 rupees, and in the case of a continuing failure, with an additional fine not exceeding five rupees for every day after the first in regard to which he is convicted of having persisted in the failure.

British Colonies.

Straits Settlements.—After the repeal of the Contagious Diseases Acts, in 1887, a registration system continued till 1895, when it was abolished, and replaced in 1896 by the "Women's and Girls' Protection Ordinance." In 1899 this was strengthened by an amendment Ordinance (promulgated August 29th, 1899), compelling keepers of brothels, under penalty, to prevent women suffering from contagious disease from remaining in the brothel, also giving power to "close brothels," on complaint being made, and penalising persons importuning or "soliciting" for immoral purposes.

Ceylon.—In Ceylon there is no special Ordinance for dealing with venereal disease. Ordinance No. 5 of 1889, however, confers the power of "closing brothels reasonably suspected of being special centres of disease."

Malta.—In Malta a local Contagious Diseases Act has been in force since 1861. This was amplified in 1898 to make it in effect an Infectious and Contagious Diseases Ordinance. (In 1909 "confidential notification" was introduced with excellent results, *vide* Table II.) Control is on the general lines of the Indian Administration.

Gibraltar.—An amended Ordinance was passed in 1901 by which "venereal diseases were included under the heading of infectious diseases." When the chief of the police has reasonable grounds for suspecting that any person is suffering from an infectious disease he may order such person to attend at the Colonial Hospital, or any other place, and to remain there till the medical officer is satisfied that such person is no longer suffering from such disease. Any person failing to comply with this order is reported to the governor. In the Colonial Hospital one lock ward is maintained for males, and two in a separate block for females. Males, unless certified to be indigent, pay for their subsistence; females are treated and supported in hospital gratuitously.

South Africa and St. Helena.—A Contagious Diseases Act was passed for Cape Colony in 1888; this was followed by a considerable diminution in the incidence of venereal disease.

A careful study will conclusively demonstrate that in a country like India, or in Malta, where, under existing administration, control by free treatment in dispensaries can be "systematically" exercised over prostitute women in a community, the result is immediately beneficial.

Again, in China, Hong-Kong, and in the Straits Settlements, control in another form exists—namely, the Women's and Girls' Protection Ordinance. Lastly, in Egypt the value of control by medical prophylaxis in military hospitals since 1899 is exemplified.

APPENDIX C.—*Contagious Diseases Acts of 1864–66 and 1869 in England.*

Major (now Colonel) Macpherson, R.A.M.C., produced a diagram at the Brussels Conference in 1899 to show the curve of venereal incidence in 14 regulated and 14 non-regulated towns in Great Britain. The results closely approximated before and after the period in which the Contagious Diseases Acts were in force, but during the period separated widely in consequence of the lowering of the rate in the regulated towns.

Dr. Kromayer (Halle) exhibited a number of tables in 1899 to show "that the Contagious Diseases Acts in England had a distinctly beneficial effect upon the incidence of syphilis, but had not affected the frequency of soft sores or gonorrhœa."

A Royal Commission in 1870 reported on the working of the Contagious Diseases Acts of 1864, 1866, and 1869, and expressed the opinion "that the worst forms of the disease had been much reduced amongst the lower class of prostitutes and that the women had also been benefited in an indirect manner." Syphilis was reduced from 40 per 1000 in 1864 to 20 per 1000 in 1870 amongst troops in the United Kingdom. "The Acts have purged the towns and encampments to which they have been applied of miserable creatures who were mere masses of rottenness and vehicles of disease." The report further says, "We are satisfied from the evidence that the frequent examination of prostitute women is the most efficacious means of controlling the disease."

The Contagious Diseases Acts did not die a quick death in England. They were in force from 1864 to 1886, and their repeal was mainly due to political reasons. The late Sir Alfred Cooper in his work on "Syphilis" in 1895 gives full details with statistics on this subject.

FOREIGN BODIES IN THE AIR PASSAGES.

BY W. G. HOWARTH, M.A., M.B., B.C. CAMB., F.R.C.S. ENG.,

SURGEON IN CHARGE OF THE NOSE AND THROAT DEPARTMENT AT ST. THOMAS'S HOSPITAL; SURGEON-LARYNGOLOGIST TO THE VICTORIA PARK HOSPITAL.

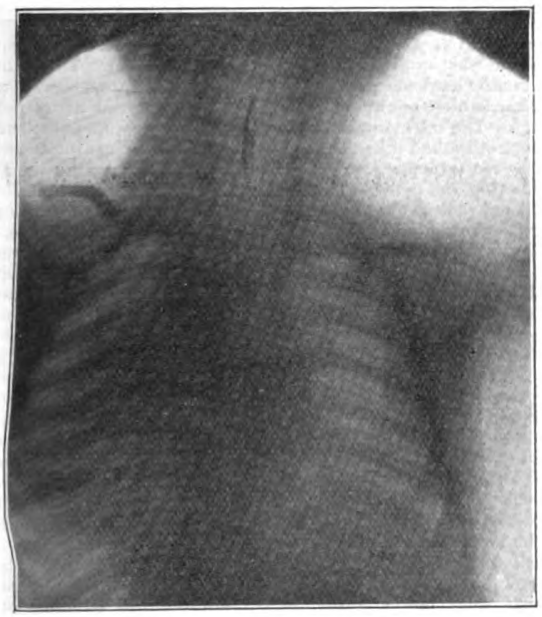
DURING the last few years the recognition and treatment of foreign bodies in the air passages have become a much simpler matter than heretofore. This is mainly due to larger experience in the use of the instruments invented by Killian, Brünings, and others for the practice of the direct method, and to the improvement that has taken place in skiagraphy. Within the last decade the number of recorded cases has grown greatly, and it would scarcely be necessary to mention the following four cases with which I have recently had to deal were it not that one at least of them presents some unusual and interesting features. In two of the cases there was a definite history of the accident and a fairly accurate description of the appearance and size of the object; in the third case the possibility was thought of when the patient was seen for another reason, whilst in the fourth case the symptoms alone brought the subject under notice.

CASE 1.—The patient was a child, aged 9 months, who, after sitting on some rugs in the garden, had been brought into the house and put to bed; shortly afterwards the mother heard a strange noise and found the little one gasping for breath and unable to make any noise when crying. A few hours after the accident an X ray photograph (Fig. 1) was taken. Under light chloroform anæsthesia a tube spatula was inserted and a jagged piece of metal was seen to be impacted in the subglottic space, the upper end just projecting between the vocal cords. The foreign body was readily extracted with a pair of Brüning's forceps, and proved to be the mouthpiece of a tin toy trumpet which had been flattened by being trodden on.

CASE 2.—The patient, aged 50, came to the hospital one morning to apply for a new tracheotomy tube which he wore permanently on account of laryngeal stenosis. It was noticed that a portion of the old tube was missing, and as he said that he had had a cough for some days an X ray photograph (Fig. 2) was taken. The tracheotomy wound and the upper part of the trachea were painted with 10 per cent. cocaine, a bronchoscope was inserted, and the foreign body, located in the right main bronchus, was extracted with forceps.

CASE 3.—The patient, aged 20, was using a hairpin as a toothpick when her brother spoke to her and made her laugh. She swallowed the hairpin and had a short fit of coughing. She came to the hospital three days after the accident complaining of pain in the left side on respiration. An X ray photograph (Fig. 3) was taken, and on the next day, under light chloroform anæsthesia after scopolamine morphine, a bronchoscope was passed. One point of the hairpin was located in the left bronchus 29 cm. from the teeth. There was a considerable degree of inflammation of the bronchial mucosa and a great deal of mucopurulent secretion, so that it was not possible to be certain where the distal end of the hairpin was situated, but as one arm of the pin seemed to be lying obliquely across the lumen of the tube it seemed probable that the distal end was in the lower lobe bronchus. Both points seemed to be impacted in the bronchial wall. Attempts to dislodge it by gentle traction with the ordinary Brüning's forceps were not successful, and as it was thought probable that a better result might be obtained by the use of a snare further efforts were postponed for a few days. In the meantime Messrs. Mayer and Meltzer constructed several powerful snares 35 cm. long, and a few days later a bronchoscope was passed and an attempt made to get the loop of the snare over one of the points and so draw the hairpin into a straight line with the tube. This manœuvre was not successful, and so a low tracheotomy was performed and the tube passed through this. It was then possible by using a tube with a sloping end to disimpact the points of the pin, pass the sharp edge of the tube over one point, grasp the other point with Brüning's forceps, and draw it into the bevelled side of the tube. The tube and hairpin were then withdrawn. The tracheotomy wound was closed. There were no after symptoms and the patient felt perfectly well the next day.

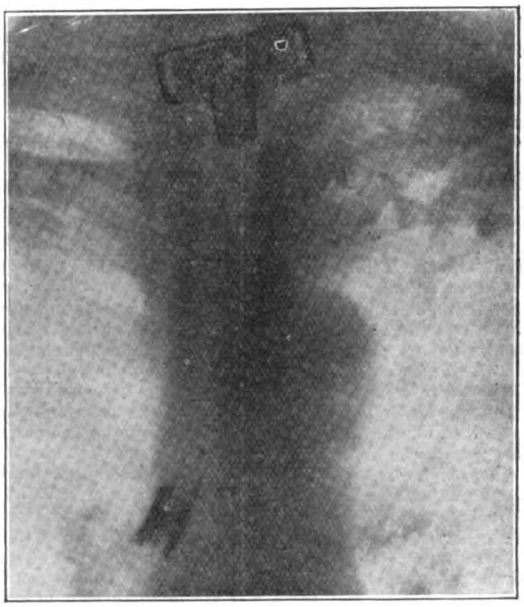
CASE 4.—A boy, aged 10½, was holding a shawl-pin in his mouth, preparatory to putting it in his tie, when he took a deep breath and swallowed it; he had a slight fit of coughing but experienced no pain in the throat or in the chest. He was seen next day and an X ray photograph (Fig. 4) was taken. Under light chloroform anæsthesia a bronchoscopic tube was passed through the larynx, the pin located point uppermost in the left main bronchus grasped with a pair of forceps, and withdrawn through the tube. The bronchial wall did not appear to be inflamed and there was no excessive amount of secretion.



A necessary preliminary to the efficient treatment of a foreign body that has been inhaled is an exact idea of the size and shape of the object and its accurate localisation. When these two matters have been satisfactorily decided, the actual extraction is not in the majority of cases a matter of any great difficulty provided that the surgeon has efficient instruments and has had some practice in the use of them. A history of the accident often defines the nature of the foreign body, but a history is not very often obtainable in the case of small children, as the accident usually occurs when they are not under observation. When a foreign body is suspected an X ray photograph should always be taken. In small children instantaneous photographs do not always give good results, and an anæsthetic may be necessary before a satisfactory result is obtained. Attention should be paid to the position of the child, so that the bony landmarks may be as definite as possible. A lateral view should always be taken as well as an antero-posterior one. In Case 1 the illustration (Fig. 1) gives but little idea of the real size or shape of the object, but it was quite evident from looking at a lateral view that the object was a flat piece of metal almost half an inch across with its sharp edge sticking forward. A lateral view also in many cases indicates whether the object is in the trachea or œsophagus, especially in the cervical region. As regards localisation, however, an X ray photograph can only give a rough idea, and the position cannot be accurately determined until a tube is inserted and a careful examination made.

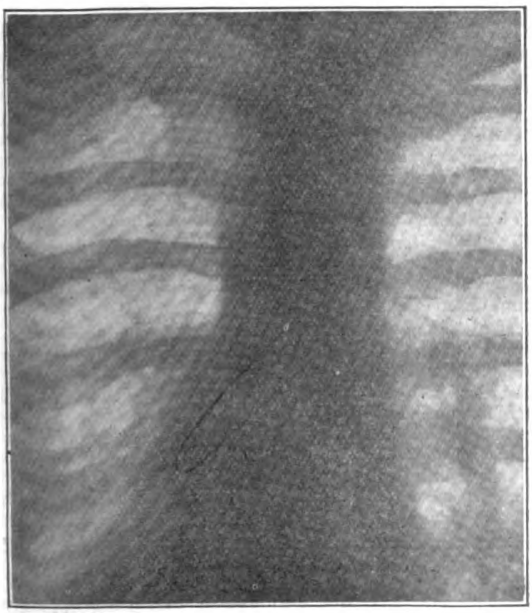
In all the above cases great help was afforded by the X ray photographs, but the objects were fortunately all metal ones and cast definite shadows. Other kinds of foreign bodies, such as beans, nutshells, or other vegetable material, are extremely difficult to see in a skiagram, and even pieces of bone, especially if they have become decalcified, are often very hard to recognise; this is particularly the case with foreign bodies in the larger bronchi, as these are apt to be much obscured by the heart shadow. In rather more than 50 per cent. of all cases a good skiagram will show a positive result, but considerable skill is required in the taking of them, and in this connexion I would express my indebtedness to Mr. Archibald Reid for the excellent ones that he provided for my cases.

In attempting accurate localisation it is well to begin by inserting a short tube spatula so that the mouth of the œsophagus and the larynx may be examined and the size of the latter estimated. If the larynx is clear the cords should be lightly swabbed with 10 per cent. cocaine and the largest size tube that seems advisable introduced. It is entirely unnecessary to drench the bronchial tree with cocaine as the mucosa is not nearly so sensitive as is usually supposed. After the main bronchi are reached excessive secretion and inflamed œdematous mucous membrane often obscure the view; the secretion should be aspirated or removed with wool mops, whilst a pledget of wool soaked in adrenalin to which a few drops of cocaine have been added markedly reduces the congestion and blanches the mucosa, thereby enabling the ring markings which are the surgeon's main rallying points to be recognised. If the main bronchi yield a negative result careful attention should be directed to the lower lobe bronchi and the middle lobe bronchus on the right side; the upper lobe bronchi are very rarely affected, which is perhaps fortunate, as they are by no means easy to explore. When the position of the object has been accurately defined the question of extraction is reached. The above cases afford examples of one of the easiest and one of the most difficult types.



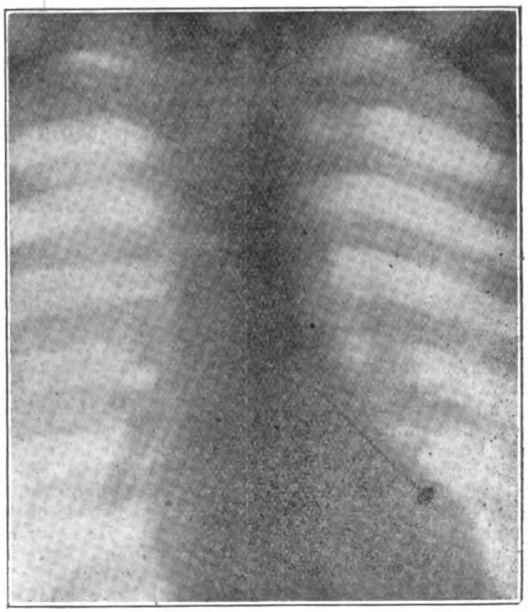
When once located it was the work of but a few moments to define the upper edge of the tracheotomy tube (Fig. 2) by

FIG 1.



CASE 1.—Mouthpiece of a toy trumpet impacted in subglottic space.

FIG. 2.



CASE 2.—Portion of a tracheotomy tube in the right main bronchus.

FIG. 3.

CASE 3.—Hairpin impacted in left lower bronchial wall.

FIG. 4.

CASE 4.—Shawl-pin in the left main bronchus.

lateral pressure on the bronchial wall, to slip one blade of the forceps outside it and extract it. The localisation was not quite so easy, as the tube closely fitted the bronchus in which it had come to rest, caused no obstruction to the airway, and had its thin upper end obscured by slight overhanging of the bronchial mucosa. The hairpin (Fig. 3) was a more difficult matter, as both ends sticking upwards were impacted at different levels in the bronchial wall, which was acutely inflamed and obscured by mucopurulent secretion. The distance of the object, and the small size of the tube that could be employed prevented both ends from being seen at the same time, and the obliquity was such that traction on one end would only result in the other end becoming more firmly impacted. As attempts to approximate the ends by slipping a snare over them were unavailing it was decided to open the trachea low down. It was thought that lower bronchoscopy would afford greater power of mobility of the trachea, and there would be no possibility of the larynx being injured, as might easily have been the case, even if extraction by the upper method had been successful. A tube was inserted through the tracheotomy wound, one end of the hairpin grasped and pushed forcibly downwards, so that both ends might become disimpacted. By using a tube with an end cut very obliquely it was possible by the aid of forceps to get the sharp edge between one end of the hairpin and the bronchial wall. The tube was then pushed down and rotated until the other end of the hairpin was opposite the obliquely cut side of the tube. It was then seized with forceps and drawn into the tube, considerable lateral pressure being exerted on the bronchial wall. The obliquely cut tube made the procedure easier than would have otherwise been the case. Paterson was the first to see the advantage of an inner tube with the end cut obliquely, and his reversal of the usual Brüning's tube which has the outer one oblique and the inner straight ended is in many cases certainly an advantage.

The other bronchial case was quite straightforward, as the rounded-glass end of the shawl-pin was in the lower lobe bronchus and the point sticking upwards (Fig. 4), so that there was no objection to upper bronchoscopy, and the pin was drawn through the tube.

The laryngeal case was rendered more troublesome by the size and jaggedness of the object, the firmness of impaction, and the delicacy of the larynx in a child of 9 months. A small tube spatula was used and just before the moment of extraction this was rotated laterally and its end pushed between the cords without loosening the hold of the forceps on the foreign body; in this way the cords were momentarily held apart whilst the object was disimpacted and guided between them without any injury occurring. It might have been expected that trouble would be caused by subsequent subglottic œdema, but fortunately this was not the case.

Harley-street, W.

ACUTE EPIDIDYMO-ORCHITIS DUE TO BACILLUS COLI.

BY W. P. BONNER, M.R.C.S. ENG., L.R.C.P. LOND.

THE patient, a man aged 45, was admitted into the London Hospital on April 24th last, under the care of Mr. Hugh Lett. Twenty days previously he "strained" himself while lifting a heavy box at work. This caused him pain in the lower abdomen which was so severe that it made him sweat. The pain ceased after a few minutes, and after passing a large amount of urine he continued with his work as usual. Four days later he complained of frequency in micturition, at first every half hour, then seven to eight times a day and two to three times during the night. He consulted his medical man about this; "the doctor gave him medicine" (no injection). Two days later he had pain in the right testicle, which came on during the night. The right side of the scrotum gradually became swollen and red. He never had any urethral discharge or pain on micturition. There was no previous history of any venereal disease; he married at the age of 20, has had a family of 13 children, and his wife is living and in excellent health. No history of coitus since 10 days previous to the onset of the frequency in micturition. No family history of any tuberculous disease.

On examination (April 24th) the patient was a poorly developed, ill-nourished man. Temperature 100·4° F., pulse 94. The urine was acid, of specific gravity 1020, and contained a considerable amount of pus and mucus. The right half of the scrotum was swollen, red, very tender, and hot; the skin was adherent at the lower and posterior part. The right epididymis was extremely tender and enlarged so much that it almost covered the right testicle. The right testicle was swollen and tender (no hydrocele). The right spermatic cord was swollen and tender throughout the whole extent, which might be felt below the external abdominal ring. The right inguinal canal was tender on palpation. The urethra had a healthy appearance and was just moistened with clear mucus. No purulent fluid could be expressed by squeezing the penis. The prostate and vesiculæ seminales (felt per rectum) were not enlarged or tender. The left side of the scrotum and its contents showed nothing remarkable.

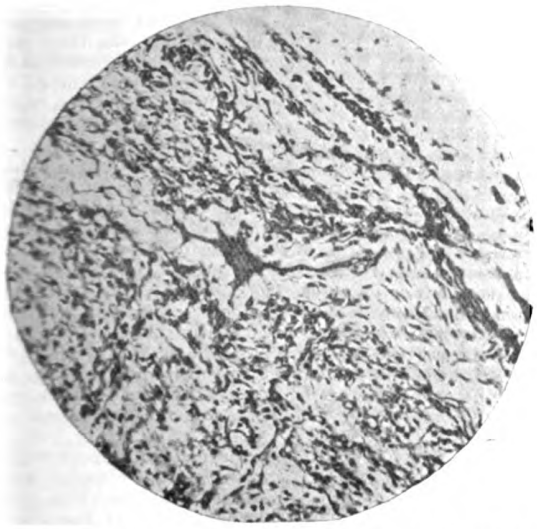
On April 30th the anterior portion of the urethra was washed out thoroughly with boric lotion. A sterilised soft indiarubber catheter of large size was passed without any difficulty, and a specimen of acid urine was drawn off. This specimen on microscopic examination showed a few pus cells and a quantity of coliform bacilli. Pure cultures of coliform bacilli were subsequently grown from this same specimen and an autogenous vaccine was prepared. On May 13th a soft fluctuating swelling appeared at the lower and posterior part of the right side of the scrotum. The skin over this area having been carefully prepared, the swelling was aspirated and a small amount of cloudy fluid obtained. Pure cultures of the coliform bacilli grew from this fluid. On May 15th the swelling (now more marked) at the lower end of the right scrotum was incised under a general anæsthetic. A small amount of material was removed which appeared to be almost entirely composed of disorganised tubules. No actual fluid pus was seen. On microscopic examination this material was found to be composed of a mass of necrosed tubules of testis and epididymis, coliform bacilli, and a few pus cells. Subsequently pure cultures of coliform bacilli were grown from this material. The urethra examined by the urethroscope appeared to be quite healthy; there was no stricture and no evidence of old or recent gonorrhœal trouble. Prostatic fluid obtained by massage of the prostate showed a few pus and epithelial cells, coliform bacilli, and staphylococci (no gonococci). Cultures taken from this fluid produced colonies of the coliform bacilli and staphylococcus albus. The coliform bacilli obtained on each of these four separate occasions were identical in structure and gave the reactions of Friedländer on sugars. Carefully taken radiographs showed no sign of any pathological conditions in the regions of the kidneys, ureters, or bladder.

The treatment of this case was as follows:—Rest in bed with the scrotum well suspended. Locally, at first, the application of moist heat in the form of boric fomentations and later (after incision) daily dry dressing with plain sterilised gauze. Medicinal: Maintaining the reaction of the urine alkaline by the administration of citrates and bicarbonates; bladder sedatives, hyoscyamus and buchu. Vaccine: Gradually increasing doses of the autogenous bacillus coli vaccine were given once a week, commencing with 5 millions and increasing up to 100 millions.

The patient has made an excellent recovery, the affected area of the right testis and epididymis being now represented by a small fibrotic nodule. The left epididymis and testis remain unaffected.

This case seems to suggest that some of the conditions of acute epididymo-orchitis of obscure origin, frequently associated with a history of strain, are due to an infection with the bacillus coli, brought on by a strain while the bladder is full of urine. I am indebted to Mr. Lett for permission to publish the case and for urethroscopic examination; to Mr. F. S. Kidd for investigating the prostatic fluid and also examining the urethra; and to Mr. T. H. C. Benians for the preparation of the autogenous vaccine and the bacteriological investigations.

A GERMAN FEMALE MEDICAL OFFICER OF SCHOOLS.—The municipal authority of Berlin has appointed Fräulein Martha Ulrich, M.D., as school medical officer, she being the first medical woman to obtain one of these school appointments.



A NEUROMA-MYOMA OF THE MESENTERY.

BY PETER PATERSON, M.B., C.M. GLASG., F.R.F.P.S. GLASG.,
SURGEON, GLASGOW ROYAL INFIRMARY.

THE patient was a boy, aged 9 years, whose development was distinctly below the average. He was unable to speak till he was 6 years old, and now he has as classmates boys who are two to three years his junior. His physical condition is as poor as his mental. Till he was 16 months old he suffered much from gastro-intestinal derangements, but as his parents belong to a class whose idea of a suitable diet for infants is of the most elementary kind probably these derangements were due to unsuitable food. From that time he seems to have remained well till the beginning of this year, when he was admitted to the Royal Infirmary with symptoms which suggested an attack of appendicitis. He had pain, tenderness, and rigidity in the right iliac fossa, constipation, and vomiting. Temperature, 101·6° F.; pulse, 136. Leucocytes 20,800, with a distinct increase in the percentage of the polymorphs.

He was operated on soon after admission by one of my assistants, who removed the appendix. This was found slightly congested, but otherwise was normal. During his residence in hospital he remained free from pain, but five months later he was readmitted with symptoms somewhat similar to those of which he complained on the previous occasion.

FIG. 1.

Section from centre of tumour showing medullated nerve fibres and ganglionic cell.

It seems that after leaving hospital the boy had severe attacks of abdominal pain, accompanied with vomiting and constipation, every seven to ten days. These attacks came on suddenly and passed off within 24 hours, leaving him apparently well. Soon after admission he had one of these attacks. The pain was so severe as to make him throw himself about in bed. It was continuous, but with exacerbations, and was felt all over the abdomen, though most marked in the lower half. Vomiting was frequent and bilious in character. There was no rise of temperature. The attack lasted 24 hours, and during that time the bowels did not act. On examination of the abdomen a smooth oval tumour could be felt in the middle line, slightly below the umbilicus. It was tender on pressure and fairly freely movable. At the operation the mass was found lying in the mesentery with its long axis parallel to the vessels and its distal end about one inch from the intestinal border. As it was encapsulated it was easily enucleated. The post-operative history was uneventful, except that for two days the patient was very sick.

The tumour was smooth, oval in shape, and measured 6·5 cm. by 4 cm. When laid open a small part at the centre presented a soft, reddish appearance, while the larger peripheral part felt and looked like a hard fibroma. Sections were made from various parts of the tumour. Those taken from the soft, reddish centre were composed, almost entirely, of medullated nerve fibres, with a very few ganglionic cells. (Fig. 1.) The fibres ran in ill-defined bundles, these interlacing one with another, and bound together by connective tissue. In sections taken from

FIG. 2.

Section from outer part of tumour showing strands of plain muscle fibres among the nerve bundles.

parts nearer the periphery strands of plain muscle fibres appeared amongst the nerve bundles, and these gradually increased on passing outwards till, under the capsule, the tissue was almost entirely muscle. (Figs. 2 and 3.) The

FIG. 3.

Section of tumour under the capsule where the tissue was nearly all muscle.

blood-vesssels were numerous, but were not well developed, the intima being the only coat that could be definitely recognised.

Both myomata and neuromata have been removed from the mesentery, but, so far as I am aware, a tumour composed of both those highly differentiated tissues is unique.

Glasgow.

THE RETRACTION RING AS A CAUSE OF OBSTRUCTION IN LABOUR.[1]

BY ROBERT JARDINE, M.D. EDIN., &C.,

PROFESSOR OF MIDWIFERY, ST. MUNGO'S COLLEGE; OBSTETRIC PHYSICIAN AND GYNÆCOLOGIST, GLASGOW MATERNITY AND WOMEN'S HOSPITAL, ETC.

I SHALL deal with this subject from the clinical side and leave the anatomical aspect of it to Dr. A. H. F. Barbour and other speakers. As to the situation of the ring, all that it is necessary for me to state is that it marks the junction of the active or retracting portion of the uterus with the portion which is passive and stretches. The part of the uterus below the ring constitutes the lower uterine segment. In an obstructed labour, say from a contracted pelvis, where the lower uterine segment is markedly thinned out and the upper segment well retracted, a sulcus can be seen and felt extending across the abdomen well up towards the umbilicus. This marks the situation of the ring. It may lie transversely or more or less obliquely. If an internal examination be made a ledge will be felt running round the uterine cavity at the upper limit of the lower uterine segment. In some cases it extends completely round, while in others, as in the specimen I show, it is not complete. It can be detected by an internal examination before its presence can be made out by palpation through the abdominal wall. I need hardly say that such an internal examination must be made with extreme care, when the ring is above the presenting part, as there is great risk of rupturing the lower uterine segment. That is what happened in the case from which the specimen I show was obtained. (See figure). It was a face presentation in a mento-posterior position, and after the ring had formed above the head forceps were tried, and then an attempt was made to do version. When the operator passed his hand in to catch a foot the patient suddenly collapsed. She was then brought into the hospital from the country, and she died in the waiting-room a few minutes after admission. We were allowed to remove the uterus, and after it was hardened it was opened, and a rupture through the muscular wall of the lower uterine segment was found of the exact shape of the back of a closed hand. The operator had recognised that there was a deep sulcus across the abdomen below the umbilicus before he passed his hand in, but he had failed to grasp its significance.

In ordinary cases of obstructed labour the ring is not the primary cause of the obstruction, but the result. However, it is not to such cases I wish specially to refer, but to those in which the ring is the primary cause of obstruction. These latter cases are not so common as the former, but when they do occur they are very much more difficult to recognise and also to deal with. So little attention has been paid to such cases that you will hardly find any reference to them in even the most recent text-books on midwifery. In some instances the ring actually forms in front of the presenting part, while in others it forms above the presenting part, just as it does in an ordinary case of obstructed labour. The presenting part may be either the head or the breech.

1. *Cases in which the Retraction Ring forms in Front of the Presenting Head.*

I have seen two such cases, both in hospital, one under my own care and the other under the care of my colleague, Professor M. Cameron.

In my case the patient was a v.-para. Her four labours had resulted in the birth of dead children, but only the fourth one had been at full time. The pelvis was flattened with a true conjugate of 3½ inches. About a fortnight before full time I admitted the patient for a thorough examination, to decide whether or not to induce labour. I found the head could be pushed into the brim of the pelvis, so I advised her to wait to full time. The lower uterine segment began to dilate, and on making an examination a few days before labour was due I found the os would admit two fingers, and the cervix was taken up. The head lay at the brim, and it could still be pushed into it. There seemed every likelihood that the delivery would not be difficult. At the expected time labour pains began, but they ceased after a few hours. To hasten matters the largest Barnes's bag was inserted late in the afternoon, but it was quickly expelled. The pains continued throughout the night, and at noon of the following day the os was fully dilated, and the membranes were bulging well into the vagina. The head was now well above the brim, and in front of it was a well-defined ledge extending round about one-half of the cavity. The head could not be pushed into the brim, as the ring prevented its descent. A full dose of morphia was given, but four hours later there was no relaxation of the ring, so I performed Cæsarean section. At the time of the operation the membranes were still intact. At the request of the patient I sterilised her by ligaturing and cutting the Fallopian tubes. Both mother and child did well.

If this patient had had a normal pelvis I would have tried to dilate the ring manually, and if I had failed I would then have done Cæsarean section; but further experience has shown me that when the ring is once well formed it cannot be dilated manually, and if I should ever meet with a case with a normal pelvis I would advise Cæsarean section.

Professor Cameron's case was a very similar one as regards the size of the pelvis, but when we examined the patient the membranes had been ruptured for several hours. The os was fully dilated, but there was a distinct ledge running round about half the cavity in front of the head. The ledge prevented the descent of the head. As in my case, the cervix and lower uterine segment were well dilated. Morphia was tried, but it had no effect, so Cæsarean section was done by Professor Cameron. Both mother and child did well.

In both of these cases the pelvis was contracted; but it was quite evident that the obstruction did not arise from the pelvis but from the ring, and I do not think that the pelvic condition had anything to do with the formation of the ring. In my case the membranes were intact and bulging well into the vagina, while in Cameron's case they had been ruptured for some hours. In the latter case, I think, the ring must have formed before the membranes ruptured, otherwise the head would have been pressed down into the brim of the pelvis, and the ring would have formed above it, as it usually does in labours obstructed by contracted pelvis, when the membranes have been ruptured for several hours.

Causes of the formation of the ring.—One cause which has been given is the use of dilating bags. In my case the largest Barnes's bag was used, but it was so quickly expelled that it is difficult to understand how it could have been the cause. I have used dilating bags scores of times without any such result. Another cause which has been given is the use of ergot. Undoubtedly, the hour-glass contraction of the uterus, which occurs occasionally during the third stage of labour, is generally due to the use of ergot. Hour-glass contraction of the uterus during the third stage of labour is caused by the retraction ring, and in one of the cases I shall shortly narrate I had a very typical example of it. In neither of the two cases was ergot used.

In the first stage of labour we occasionally meet with a spasmodic condition of the os, where the circular fibres round the os have not been inhibited, and these fibres contract along with the fibres in the main body of the uterus, so that the os actually gets smaller instead of larger with each uterine contraction. Now, there is a considerable resemblance between the circular fibres round the os and the fibres of the retraction ring, and what causes the spasm in the former may cause it in the latter. Spasmodic contraction of the os is generally supposed to be due to an irritant which acts reflexly. I make this suggestion, but I must confess it is not much of an explanation.

Diagnosis.—There is no apparent obstruction to the advance of the head, and yet the labour is delayed, although the uterine contractions are strong and frequent. The uterus may be in a tetanic condition without any relaxation between the pains. On palpating the abdomen you will find that the head is well above the brim of the pelvis, and you cannot push it down. If the abdominal wall is thin you can feel the ring, but with a thick wall you may not feel it. On making a vaginal examination you find the os dilated and the lower uterine segment opened up, but some three inches or so above the os you feel a distinct ledge running round a portion or the whole of the uterine cavity in front of the head. During a pain this ledge does not relax, but it becomes more prominent and prevents the advance of the head. The membranes may or may not be ruptured. If

[1] A paper read at a meeting of the Edinburgh Obstetrical Society on May 14th, 1913.

they are intact they protrude into the vagina, and they may even be seen at the vulva.

Prognosis.—If the condition is recognised in time both mother and child should be saved; but, unfortunately, in many of the recorded cases a definite diagnosis was only made when exhaustion had set in, and there was little chance of saving either mother or child.

Treatment.—If the child is alive I am convinced that Cæsarean section is the proper treatment. Full doses of morphia or opium have been recommended, but I have never seen any effect in causing relaxation in a number of cases in which morphia has been used freely. Manual dilatation has also been advised, but the hand is powerless in such cases. Incision of the ring has been advised, but it would be impossible to prevent the incisions extending, and this would end in rupture of the uterus. Hydrostatic bags are useless, as you cannot introduce them high enough to bear upon the ring. If the child is dead it could be delivered by craniotomy, provided you have an instrument which will enable you to make powerful traction. If the shoulders are caught the clavicles should be cut.

2. *Cases in which the Retraction Ring forms Above the Presenting Head.*

In these cases the membranes rupture before there is much dilatation of the os, or even before labour has begun. The first stage of labour is very prolonged, and by the time the os is fully dilated the ring has formed above the head round the neck of the child. There is no descent of the child, because the shoulders are obstructed by the ring. The case, from which the specimen I show was obtained (see figure), was probably of that nature, although it was a face presentation with the chin to the back. The pelvis was a very roomy one, and there was no reason, so far as the pelvis was concerned, to prevent descent, even with the chin in a posterior position. However, I did not see this case until the patient was dying, so I cannot give the particulars in regard to the labour.

Rupture of the uterus showing the retraction ring. The posterior wall of the uterus is removed.

The following cases are typical examples of the condition:—

CASE 1.—The patient was a multipara with a roomy pelvis. Her previous labours had been easy ones. The membranes ruptured at the commencement of labour, and the medical attendant, Dr. Thomas Holmes, gave opiates to relax the cervix, and waited on nature to cause dilatation. After waiting many hours he found the pressure was beginning to tell on the child, and as the mother was showing signs of exhaustion he decided to deliver with forceps. The os was not quite fully dilated, but full dilatation was easily effected manually. The head was high up in the first position, and not in any way obstructed. He applied Milne Murray's axis traction forceps, but they slipped, after holding well for some time. He then passed his hand in, and recognised that the retraction ring was firmly gripping the neck of the child. I was called in consultation with Dr. E. H. L. Oliphant, and I found that the head was above the brim of the pelvis, and there was no obstruction below it to prevent its descent, but on passing my hand above it I found the retraction ring was gripping the neck all round. I had never before seen such a complete ring. The finger tips could be pushed between the neck and the ring, but it was impossible to dilate it. I could not detect any fœtal heart sounds, but Dr. Holmes thought he had heard them shortly before my arrival. We discussed the propriety of doing Cæsarean section, but decided against it, as there seemed very little chance of saving the child, and the condition of the mother was not very favourable. Under deep anæsthesia I tried axis traction forceps again, but they again slipped, after holding well for some time. I then perforated the head, and applied my combined instrument, which obtained such a powerful grip of the head that I was able to overcome the resistance of the ring and deliver the child. There was no bleeding during the third stage of labour, but as the placenta did not come away in the usual time, and suprapubic pressure failed to dislodge it, I passed my hand into the uterus and found that the placenta was separated, but it was gripped by the ring. It was a typical case of hour-glass contraction of the uterus during the third stage of labour. I removed the placenta and gave an intra-uterine douche. The patient was very exhausted, but with free stimulation and rectal saline injections she rallied and made a good recovery.

CASE 2.—I saw this case in consultation with Dr. T. C. Barras. The patient was a stout i.-para with a very roomy pelvis. During her pregnancy she had suffered from an irritating vaginal discharge, which was treated by douching and swabbing out the canal. For several days before the actual onset of labour she had complained of pains which were evidently false ones, as no dilatation had occurred. When labour set in the membranes ruptured early, and the dilatation was very slow. After a good many hours the patient was becoming exhausted, so Dr. Barras decided to deliver her. The head was partly fixed in the brim of the pelvis, and on pushing it up to pass a catheter a gush of extremely foul liquor amnii came away. The odour was so bad that the anæsthetist suggested that surely the small intestine had given way.

I was called in, and found the head partly in the brim (L.O.A.), and it was not obstructed in any way. The stench from the liquor amnii was very overpowering. I emptied the bladder and applied Milne Murray's forceps, and with considerable difficulty got the head down, but not quite free of the vulva. The posterior vaginal wall and perineum gave way, but the sphincter ani remained intact. It was quite evident that the body was being obstructed, so I passed my hand up by the side of the head and found that the neck was tightly grasped all round by the retraction ring. The whole uterus had been pulled down, so the ring was about the level of the brim. I could get the tips of my fingers between the ring and the neck, but on trying to dilate the ring I could make no impression upon it, and my hand quickly became powerless. As the child was now dead, I passed a crotchet in and tore the right clavicle out, and removed the right arm. Even then the body would not come through, so I broke the clavicle of the other side, and by making traction with the crotchet hooked into the chest, and pulling on the head, the body was delivered. There was no great difficulty with the placenta. After douching and cleansing the parts I repaired the vagina and perineum.

The patient was very exhausted, but she soon rallied. She passed through a very stormy and prolonged puerperium, but ultimately recovered. Septic absorption occurred through the vagina, and she

developed a pelvic abscess in the right side, which burst into the vagina. I dilated the sinus and evacuated large quantities of very foul-smelling pus on several occasions, but it was impossible to get free drainage even through a large vulcanite tube. Finally, openings had to be made in two places above Poupart's ligaments, in the right labium majus and in the thigh. An attempt was made to obtain a vaccine, but the bacteriologist reported that there was such an enormous growth of bacteria that he could not prepare one. The uterine cavity seemed to have escaped infection, as the discharges from it remained quite normal. The septic liquor amnii had nothing to do with the formation of the retraction ring. I have seen the same condition in several other cases, where the membranes had ruptured at the commencement of labour.

Causes.—The membranes rupture before there is any dilatation of the os, and the uterus soon gets moulded round the child. During the slow dilatation of the os retraction takes place, and the ring forms round the neck of the child; but there must be more in it than that, because we see many cases where the membranes rupture early, and many hours elapse before the os is fully dilated, and there is no obstruction to the advance of the body. There must be a determining cause, but it is difficult to say what it is.

Diagnosis.—If the patient is thin palpation will reveal the presence of the ring. Both of these patients were too stout to allow of this. An internal examination reveals that the head is high up, but it is not obstructed, and on passing your fingers beyond the head you feel the distinct ledge in front of the shoulders.

Prognosis.—If the condition is recognised early the chances for both mother and child should be good; but if it is only recognised after attempts to deliver have failed, then the prognosis is unfavourable, especially so for the child.

Treatment.—Opiates seem to have no effect in causing relaxation. In Case 1 several doses were given to assist the dilatation of the os, but this did not prevent the formation of the ring. Manual dilatation I have found useless. If the forceps will hold you may be able to drag the shoulders through, but in my second case I failed. When the child is alive undoubtedly the proper treatment is Cæsarean section. It will be necessary to divide the ring to allow extraction of the head, as occasionally has to be done in contracted pelves, where the membranes have been ruptured for some time and retraction has occurred. When the child is dead a crushing instrument which will take a powerful grip of the head, such as my combined instrument, will enable you to drag the shoulders through. Division of the clavicles will facilitate this. Version is of course contra-indicated.

3. *Cases in which the Retraction Ring Forms in Breech Presentations.*

When the legs are extended in a breech presentation impaction generally occurs. The breech comes into the brim, and there it sticks, although strong contractions are occurring. The usual explanation that is given is that the extended legs act as splints and prevent lateral flexion of the body. A splint should be rigid, and it should be firmly fastened if it is to prevent movement. I fail to see how the extended legs of a child fulfil these conditions. Not only are they hinged at the knees, but they are fairly flexible sideways, and they are only firmly fastened at the hip-joints. The upper end of the supposed splint is not firmly fixed.

When the legs are extended I believe that the true cause of the impaction is the retraction ring gripping the child behind the knees, so that its legs and feet are hitched above the ring. In these cases the membranes rupture early, and the whole of the liquor amnii drains away, and the uterus becomes moulded round the child. By the time the os is fully dilated the ring has become a very palpable ledge inside the uterine cavity, and with each uterine contraction it contracts and grips the child so firmly that descent is prevented. I have frequently demonstrated this to my residents in the hospital. In two instances in which I was called in consultation, after the attendants had failed to deliver by traction on the breech, both of the men told me that they had found a ledge inside the uterus which was causing the obstruction. In one of these cases the attendant had tried to deliver with a blunt hook, using all his strength, but had failed. When I delivered the child alive I found a large wound in its groin, which I had to stitch.

Diagnosis.—When the breech is impacted always suspect extension of the legs, and pass your hand in along the front of the child, and you will feel the ledge. You may be able to palpate it through the abdominal wall, but it can be recognised much earlier, and more easily, by an internal examination.

Prognosis.—The risks to the mother are very small if proper precautions are taken, and to the child they are not much greater than in an ordinary breech case which requires artificial delivery.

Treatment.—Traction upon the breech by forceps, fingers, fillets, &c., is of little use, and as for a blunt hook it should never be used on a live child. Have the patient deeply anæsthetised, then pass your flattened hand in carefully along the front of the child until you reach a foot, then sweep it inwards over the front of the child and bring it down. This must be done with care, as the lower uterine segment is thinned out, and if care is not taken it may be ruptured. When the leg is brought down make traction upon it, and get an assistant to keep up firm pressure upon the fundus of the uterus to prevent the arms going up and to keep the head well flexed. If the arms are caught they must be relieved by sweeping them over the front of the child, and the after-coming head must be dealt with in the usual way.

I do not think that sufficient attention has been paid to the retraction ring as a cause of obstruction in labour, and I trust the subject will be fully discussed. It is a rare complication of labour, but my experience shows me that it is commoner than is generally supposed. I have seen other cases than those I have mentioned; and in looking back I can recall a number of extremely difficult cases with which I have had to deal, which puzzled me at the time, but which I now recognise were cases of this kind.

Glasgow.

TUBERCULOSIS OF THE UTERUS.

BY J. W. THOMSON, M.A., M.B., C.M. ABERD.,
ASSISTANT SURGEON, WAKEFIELD GENERAL HOSPITAL.

TUBERCULOUS disease of the uterus may be primary or secondary, usually the latter, the source of infection being a tuberculous salpingitis; but the infection may also be conveyed by metastasis through the blood stream, or directly by coitus, as pointed out by Montgomery.[1] Tubercle bacilli have been found in the semen of phthisical patients. Those rare cases in which no other tuberculous focus is found constitute the primary form.

Three varieties may be described—the corporeal, the cervical, and the combined or cervico-corporeal form. The corporeal is the most common form and may be miliary or ulcerative, and is strictly confined to the body of the uterus, ending, it may be, abruptly at the internal os, as in Stewart's cases.[2] The disease may present the features of an ordinary endometritis, the true nature being only revealed on microscopic examination, or it may involve the musculature of the uterus in varying degrees. The cervical canal may be blocked, resulting in a tuberculous pyometra—the so-called uterine phthisis. Montgomery reports a case in which the disease was confined to the myometrium and had originated there, and was probably transmitted by the blood-vessels. The cervical variety is rarer and may be of the miliary, ulcerative or papillary form, resembling the venereal wart or early carcinoma, but is less friable than the latter, has less tendency to bleed, and there is free muco-purulent discharge. There may exist tuberculous disease elsewhere, and the microscope would decide. The cervico-corporeal form is of extreme rarity. The following is an example of the corporeal variety.

The patient, aged 20, had no family history of tuberculous disease. At the age of 13 an operation was performed for dysmenorrhœa. At the age of 18 several attacks of appendicitis were followed by the operation of appendectomy, which I am told was excessively difficult owing to pelvic adhesions. For two years fairly good health was enjoyed, after which she was again admitted to this hospital suffering from frequent, urgent and painful micturition. The dysuria soon subsided with appropriate treatment. A large amount of pus was present in the urine, which was acid and of normal quantity. No tubercle bacilli were discovered in it, but the bacillus coli abounded. Inoculated guinea-pigs died

[1] Keen's Surgery, vol. vi.
[2] Glasgow Medical Journal, April, 1912.

in a few hours. From time to time the pus greatly diminished in amount or actually disappeared, and this was accompanied by pain in the abdomen and a rise in the temperature, which was at other times normal. As a rule there was no pain or tenderness and no rigidity. Von Pirquet's test was negative. Vaginal examination revealed a much thickened right ureter and a somewhat thickened left ureter. The uterus was fixed in the retroverted position. Cystoscopy was difficult and no abnormal communication with the bladder was found. There were some tubercles round the right ureteric orifice. Neither kidney was palpably enlarged, and the amount of pus was too large to be derived from a kidney that was not easily palpable. Accordingly, the abdomen was opened by a paramedian subumbilical incision.

To the left side of the retroverted uterus over an area of the size of a florin the bladder was densely adherent. On separating these structures a communication was found to exist between them admitting the index finger, on the one hand into the bladder and on the other hand into the uterus. The friable bladder wall was sutured with difficulty. The pelvic colon running from right to left was firmly attached to the fundus of the uterus. This was separated and the wall of the intestine repaired. The uterus was with ease separated from the rectum, the finger merely traversing soft granulation tissue, but leaving an aperture an inch in length in the rectal wall. The lumen of the rectum was narrowed as in Jellet's case.[3] (Periodic attacks of diarrhœa were recorded.) The Fallopian tubes were hard, irregular, and thickened. These were freed, and the uterus was now attached to the cervix by a narrow ragged pedicle, which was divided. The uterine arteries were not encountered, being obliterated probably by a tuberculous endarteritis and finally disappearing. The internal os was obliterated. In sharp contrast to the condition of the body of the uterus was that of the cervix, whose peritoneal coat was intact, and it might at first sight have been mistaken for the sutured stump of a supravaginal hysterectomy. It almost seemed as if an attempt was in progress by the serous membrane to entirely separate the healthy cervix from the tuberculous body—a serous line of demarcation. A suprapubic drain was introduced.

The interior of the uterus presented two abscess cavities, the one above-mentioned. Above this was a small section with normal lumen. Above this, again, was another abscess lined with tuberculous granulation tissue and containing some calcareous particles. The wall of the uterus showed much caseous material. The left ovary was not found, the right was of normal size and consistence, and lay on the floor of the pelvis in what seemed to be a separate compartment of peritoneum, and was not disturbed. Certainly on the surface of the right kidney, and I think also on the left, tuberculous nodules were felt due to ascending infection by the periureteral lymphatics.[4] There were no tubercles on the peritoneum.

Pus disappeared at once from the urine; a little albumin remained. The expected fæcal fistula developed. There was a slight gain in weight, and the patient left the hospital with a lessening fistula and is now undergoing special treatment.

Histology.—The following report is by Dr. M. J. Stewart, clinical pathologist, Leeds Infirmary: "Three separate portions have been examined microscopically and all show the same appearance. The myometrium is infiltrated by large masses of tuberculous granulation tissue, composed of innumerable aggregated giant-cell systems. Some of the larger masses are the seat of central caseous necrosis, but this is not a prominent feature. The process is a fairly acute one, and there is little or no attempt at peripheral fibrosis. The tubercles are quite characteristic, and large well-formed giant-cells occur with great frequency. The endometrium appears to be completely destroyed. Examination of the tube (one only) shows that the mucosa is still intact and is the seat of numerous typical tubercles. The lesion appears to be a recent one or there would be more destruction of mucous membrane. Several sections have been stained by Ziehl-Neelsen's method, but I can find no tubercle bacilli in the uterus. In the tube, however, one of the giant-cells contains a tubercle bacillus."

Remarks.—Patel[5] states:—

Hysterectomy is only allowable when the disease is limited, as in an adenomyomatous tumour of the uterus which has undergone tuberculous degeneration, or a common fibroid, or even a carcinoma which may undergo similar degeneration, while when the tuberculous disease is more of the inflammatory than the neoplastic type, constitutional and specific treatment is necessary, surgery being dangerous. When, however, the appendages are implicated the uterus should be removed entire with Fallopian tubes and ovaries, subtotal hysterectomy being unsurgical.

In the above case operative treatment was obviously indicated, and I am convinced that if a diagnosis had been effected at an earlier stage subtotal hysterectomy followed by vaccine therapy and the general treatment of tuberculosis there would have been excellent prospect of cure. In cervical tuberculosis high amputation of the cervix or even curette or cautery may bring about a cure.

Early diagnosis of the corporeal form, both as regards the existence and the extent of the disease, must be excessively difficult and of supreme importance. Dr. Jellett points out that he has never found tuberculous disease of the uterus that did not eventually lead to serious complications. The development of these serious complications — such as implication and perforation of the bladder with resulting pyuria, involvement of the ureters and kidneys, severe hæmorrhage, recto-vaginal fistula, &c.—would lead to further investigation and elucidation of the case. It must, however, be our endeavour to prevent these calamities. If a tuberculous lesion is found elsewhere, and there also exists any pelvic trouble, it would be well to think of tuberculous disease of the uterus and employ energetic treatment. We must remember, too, that, as in the case reported above, an attack of appendicitis may be the signal that all is not well in a tuberculous sense with the pelvic organs. Hence those small incisions, the practice of many, the boast of some, are to be much condemned, for through these thorough examination of other organs is impossible. In cases of endometritis, anyhow of obstinate endometritis, the uterine scrapings should be submitted to microscopic examination, and if found to be tuberculous extirpation must be practised to avert the final horrors of the disease.

Reviews and Notices of Books.

A Text-book of Midwifery for Students and Practitioners. By R. W. JOHNSTONE, M.A., M.D. Edin., F.R.C.S. Edin., M.R.C.P. Edin., Assistant to the Professor of Midwifery and to the Lecturer on Gynæcology in the University of Edinburgh, &c. London: Adam and Charles Black. 1913. Pp. 485. Price 10*s.* 6*d.* net.

THIS book has been designed primarily to supply students with a text-book of convenient size, but special attention has been given to practical points and to the management of normal and abnormal cases, so that it may also prove useful to practitioners. The early chapters on the development of the ovum and placenta have already appeared in almost their present form in the author's "Outlines of Early Development." They are good and up to date, are much simplified by the omission of all references to comparative embryology, and the description has not been carried beyond the organs that have a direct bearing upon obstetrics. The book is of interest since it is to a large extent a *résumé* of the teaching of the Edinburgh School of Obstetrics, or perhaps it would be more correct to say that of Sir John Halliday Croom, to whom the work is dedicated.

It is always disappointing to find in a manual of this kind small inaccuracies which could easily have been avoided. For instance, in discussing the height of the fundus of the uterus at the various months of pregnancy, on p. 79 we are told that at the end of the fourth month of pregnancy the level of the fundus of the uterus—by this no doubt the author means the upper border of the fundus—is about two inches above the symphysis pubis. In Fig. 53 it is correctly shown at a point about opposite the fifth lumbar vertebra,

while in Fig. 54 at the sixteenth week it is represented as about one inch or so above the symphysis pubis. What is the student to believe? A reference to the well-known sections of Bayer and Waldeyer would have shown the author that the fundus of the pregnant uterus at the fourth month reaches about 4·8 inches above the symphysis pubis, or as it is represented in Fig. 53, while at about the third month it reaches some 2·8 inches above the symphysis pubis, as is shown in Fig. 52 but not in Fig. 54. Many years ago Pinard proved that at the twentieth week of pregnancy the fundus of the uterus practically always reaches the umbilicus, and the researches of Kakouchin have demonstrated that as a general rule the umbilicus is at a distance of 15 cm. from the symphysis pubis. It is essential that the authors of text-books should be accurate in their anatomical statements, and there is already much confusion in the minds of students as to the height which the fundus of the uterus attains at the various months of pregnancy.

In describing the use of a Champetier de Ribes bag in the treatment of placenta prævia the author does not mention the important drawback that not infrequently between the expulsion of the bag and the delivery of the child, more particularly when the head has been displaced from the pelvic brim, there is a serious risk of the occurrence of severe hæmorrhage. It is, perhaps, a pity that Dr. Johnstone has given a diagram of the ammonia coefficient of the urine in different conditions, but has not stated that a great deal of doubt has been thrown by various observers upon the deductions originally drawn by Whitridge Williams from an estimation of this coefficient, more especially as the latter has in consequence somewhat modified his original views.

Although we have indicated a few points upon which we differ from Dr. Johnstone, yet this does not mean that we do not approve of the book as a whole; on the contrary, we regard it as a very excellent example of its kind, and one which we can certainly recommend to students.

Allen's Commercial Organic Analysis. Vol. VII. Fourth edition, entirely rewritten. Edited by W. A. DAVIS, B.Sc., A.C.G.I., and SAMUEL S. SADTLER, S.B. London: J. and A. Churchill. 1913. Pp. 563. Price 21*s.* net.

THE present volume, the last but one of the series, deals with the vegetable alkaloids, glucosides, non-glucosidal bitter principles, animal bases, animal acids, lactic acid, cyanogen and its derivatives, and hence it contains allusions of distinct medical interest. This is particularly obvious in the monograph on the animal acids by J. A. Mandel, D.Sc., in which the chemistry of the acids of urine, bile, and biliary pigments is considered. The title of this section may call for criticism, for, as the writer points out, the acids occurring in the animal kingdom are in many instances found also in plants, while a large proportion of them have been prepared by artificial means. But, as he continues, no sharp distinction can be drawn between substances of acid function found in animals and the organic acids from other sources, just as no distinction can be drawn between animal bases and vegetable alkaloids. There are, of course, other "animal acids," as, for example, the fatty acids, lactic acid, acids of the cyanogen group, but these are dealt with in other chapters, so that in reality the author in this section confines himself to a consideration of chemio-pathological products—viz., urinary and biliary acids. The analytical methods described are satisfactory, and for the most part represent recent work upon the subject. We are glad to note that the use of glucose instead of cane sugar is mentioned in the Pettenkofer test for biliary acids. It is a great advantage that glucose, unlike sucrose, does not char in strong cold sulphuric acid. The paragraphs on the examination of calculi are very good, but a misprint in the page heading has been overlooked where on two occasions we find "urinary balculi." In the chapter on vegetable alkaloids room has been made for what may be called "overmatter," for already these bodies have been considered under the same heading in a previous volume. But we are told that "there remain a number of vegetable bases which are of interest or importance from their employment in medicine (e.g., emetine, physostigmine, pilocarpine), their marked poisonous character (e.g., gelsemine, colchicine), or their occurrence in condiments (e.g., piperine)." This division of the subject, by which part of it is treated in one volume and part in another, is somewhat inconvenient in the matter of reference.

There is a valuable contribution on the glucosides by Dr. E. Frankland Armstrong, in which many important substances are described, the paragraphs showing references to recent work upon the subject. Salicin, mustard, digitalis, strophanthus, the saponins, jalap, and scammony are included in the group. The succeeding monograph on the non-glucosidal bitter principles furnishes also a good specimen of modern research. It includes the important substances, aloes, colocynth, cocculus indicus, and hops. In a short section on putrefaction bases (the ptomaines) the writer correctly points out that these bases are in general not poisonous. "Most so-called cases of ptomaine poisoning," he adds, "are in reality infections with a pathogenic organism."

The series provides a set of volumes of service not only to the analytical chemist, but also to the pathologist and the practitioner.

Headache: its Varieties, their Nature, Recognition, and Treatment. By Dr. SIEGMUND AUERBACH, Chief of the Polyclinic for Nervous Diseases in Frankfurt. Translated by ERNEST PLAYFAIR, M.B., M.R.C.P. Lond. London: Henry Frowde and Hodder and Stoughton. 1913. Pp. 208. Price 5*s.*

Le Mal de Tête. Par Dr. SIEGMUND AUERBACH. Traduction Française par le Dr. A. FRAÇNON. Paris: Vigot Frères. 1913. Pp. 220. Price 3.50 francs.

WE have received an English and a French translation of Dr. Siegmund Auerbach's work on headache. The full title reads, "Headache: its Varieties, their Nature, Recognition, and Treatment; a Theoretical and Practical Treatise for Students and Practitioners." This description fully indicates the nature of the work. Only those forms of pain are described which are referred by the patient to the interior of the cranium. The neuralgic pains which are referred to the exterior of the cranium in the course of the fifth and other nerves are not dealt with in detail, although reference is naturally made to them from the point of view of diagnosis.

Dr. Auerbach classifies the different forms of headache as follows: (*a*) The more independent forms of headache; (*b*) headaches associated with diseases of individual organs; (*c*) headache in general diseases; (*d*) combination of different forms of headache—so-called habitual headache. The remarks on the first group will be found the most interesting, as the author propounds some original views as regards the pathogenesis of the pain. Migraine is the first affection considered, and a good account is given of its symptomatology, stress being laid on the hereditary character of the disease, the periodicity of the pain, and its occurrence in attacks. In discussing the pathology, Dr. Auerbach arrives at the conclusion that the symptom-complex of migraine can most plausibly be explained if it is assumed that the predisposition depends upon a disproportion between cranial capacity and brain volume, and that the attacks are brought on by exciting causes which, through the action of the vaso-motor mechanism, are

calculated to exaggerate this disproportion. It is certainly difficult to find a satisfactory explanation of the pain in migraine, but we are not convinced by Dr. Auerbach's arguments; the view that the symptoms arise from stimulation of areas in the central nervous system, and that this stimulation may be provoked in many ways, has more evidence to support it. The symptomatology of the neurasthenic, or exhaustion, headache is clearly described, and the differential diagnosis discussed. "Nodular (rheumatic) or induration headache" is considered at some length, and Dr. Auerbach is of opinion that from one-fifth to one-fourth of all headaches are of this form. Attention is drawn to the hard, sometimes flattish, sometimes raised infiltrations which can be felt over the occipital bone and mastoid process. The most successful treatment, he considers, for this variety of headache is manual massage.

A good deal of interesting information not contained in ordinary text-books will be found in this volume, and we can recommend its perusal to those engaged in general practice. Dr. Playfair has performed his duties of translation into English in an eminently satisfactory manner.

Handbuch der Hygiene. Herausgegeben von Professor Dr. M. RUBNER, Geh. Medizinalrat, Berlin; Professor Dr. M. VON GRUBER, Obermedizinalrat, München; und Professor Dr. M. FICKER, Berlin. III. Band (1. Abteilung). Pp. 853, with 146 illustrations. Price, paper, 27 marks; bound, 30 marks. III. Band (2. Abteilung). Pp. 536, with 73 illustrations and 25 coloured plates. Price, paper, 24 marks; bound, 27 marks. IV. Band (1. Abteilung). Pp. 483, with 92 illustrations. Price, paper, 15 marks; bound, 18 marks. Leipzig: S. Hirzel. 1912 and 1913.

IN our issue of March 2nd, 1912, we gave a review of I. Band and II. Band (2. Abteilung) of this work. Since then three further volumes have been received. These volumes are apparently not being issued in regular sequence, as IV. Band (1. Abteilung) reached us in December, 1912. III. Band (2. Abteilung) in June, 1913, and III. Band (1. Abteilung) in August, 1913. Like the preceding volumes, those at present under review consist of contributions from numerous authors in the form of a series of articles on various branches of hygiene. The contributors seem to have been well chosen, and their position in the scientific world is sufficient guarantee of the general excellence of the text. It is of course impossible within the limits of a review to do more than touch on some of the salient features of a work of such magnitude, but we can in this way give a good idea of the subjects discussed in the present volumes.

III. Band (1. Abteilung) contains much that is of interest to the student of preventive medicine in the broadest sense of the term. It is prefaced by a historical survey of the chief discoveries and events in the world of research which have led up to our present knowledge of bacteriology and kindred subjects. Commencing in the early days of Egyptian history, the advancement in the science and art of medicine is traced in a fascinating manner by Professor Ficker, who is apparently well acquainted with the subject. The article concludes by pointing out that the rapid strides made by hygiene in recent years have, in no small manner, been due to the facts elucidated by the study of diseases of bacteriological origin. The next section, by Th. Muller, is devoted to a description of the general morphology of bacteria, moulds, yeasts, &c. The principle of the microscope suited to bacteriological work is briefly explained, and the ultramicroscope and other apparatus are alluded to. The preparation of microscopical specimens of bacteria, their staining, and the form and structure of micro-organisms are shortly put before the reader. The general biology of micro-organisms forms the subject of the following section, in which Professor Ficker describes the influence of nutriment, temperature, and other agencies on these low forms of life, whilst, among other matters, the part played by micro-organisms in the production of alcohol, the souring of milk, and so on, is touched upon. Qualitative and quantitative bacteriology is the heading of the next section, which seems somewhat misleading—at least to our conception of the term—as the entire section is devoted to a description of the different methods employed by the bacteriologist for the counting of bacteria. General epidemiology is next considered by Emil Gotschlich. This section is divided into two parts, the first of which deals with the modes of infection, and the second with the characteristics of different forms of epidemics. In the first part the subject is discussed under the following headings: (1) Source of Infection; (2) Manner in which it is Spread; (3) Mode of Entrance into the System; and (4) Results Produced. The factors which influence the spread or decline of epidemics are put forward in the second part, which also contains a tabular statement summarising the epidemiological characteristics of the different infectious diseases. The three concluding sections of this volume deal with prophylaxis, disinfection, and immunity.

III. Band (2. Abteilung) is devoted almost exclusively to the etiology of infectious diseases, and might fitly be described as a text-book on bacteriology. It is illustrated by many drawings in black and white, and by numerous coloured plates of the microscopical appearances of micro-organisms, their cultural characteristics when grown on artificial media, and dissections of experimental animals. These illustrations are good without being exceptionally so. There is a tendency in this volume, as is perhaps natural, to give prominence to the work done by German investigators. In the section dealing with yellow fever one would have expected that mention would have been made of Seidelin's yellow fever bodies. It is true that, excepting among his own pupils, their presence has not been confirmed, yet in a work of reference some allusion to them might at least have been expected. The article on plague is also surely incomplete without a detailed description of the epidemic in Manchuria during the winter of 1910–11. The excellent work done by English bacteriologists in elucidating the etiology of meat poisoning is not mentioned in the paragraph dealing with that subject. On the whole, however, this volume contains much useful information on the ever-widening field of bacteriology, and its value is enhanced by the addition of a well-selected list of references to the literature of the subject.

IV. Band (1. Abteilung), which relates to the hygiene of school life, hospitals, disposal of the dead, poverty, prisons, school hygiene, and the organisation of the public health service by the State and community, applies more particularly to conditions as they exist in Germany, and its interest therefore principally lies in its affording a means of comparison of German conditions with those of other countries. This volume is well illustrated, and contains some interesting plans of hospitals, schoolhouses, and institutions.

The Practitioner's Vade Mecum, or How to Cut the Drug Bill. By A. HERBERT HART, M.D., M.S. Durh. Third, or National Insurance, edition. London: John Bale, Sons, and Danielsson, Limited. 1913. Pp. 122. Price 2*s.* 6*d.*

IN this little volume numerous practical suggestions are made which will prove of value to the medical practitioner. That the book has been appreciated is demonstrated by the fact that a third edition has been found necessary.

One of the features indicated in this book is a systematic and universal adoption of abbreviations. The author strongly urges that initials should be adopted to indicate certain

prescriptions: for instance, M.A.C. would mean mistura ammonii chloridi. In hospital practice this principle is largely adopted, "Mist. gent. alk.," for example, indicating a certain combination of drugs, the reason for this practice being that when large numbers of patients have to be seen in a limited period much time and trouble is therefore saved, especially in the dispensary. The universal adoption of such a method would lead to rather a rule-of-thumb method of treatment, and it is certainly not advisable for students to learn the art of prescribing in that manner. Nevertheless, for minor maladies it has its advantages, but we doubt whether it would be wise for practitioners and pharmaceutical chemists to adopt the plan of "symbolism" in the wholesale manner suggested by Dr. Hart. Another object of this work is to lower the expenses of the drug bill for general practitioners by the institution of standardised liquid extracts for the spirits, tinctures, and wines of the British Pharmacopœia. Dr. Hart explains that in the preparation of the liquid extract the alkaloid is first extracted by means of alcohol, which is subsequently removed by exhaustive distillation. Those who have been occupied in general practice would be able to judge as to whether this recommendation is worthy of wide adoption.

The book contains a good amount of practical information as regards drugs and dispensing, and useful hints are given concerning invalid foods. We believe that it will be found useful in general practice.

Dysenteries: their Differentiation and Treatment. By Major LEONARD ROGERS, I.M.S., Professor of Pathology, Medical College, Calcutta. Illustrated. London: Henry Frowde and Hodder and Stoughton. 1913. Pp. 336. Price 10*s.* 6*d.* net.

Major Leonard Rogers's name as an investigator is well known in all medical and scientific circles. For ten years or more he has had exceptionally favourable opportunities for studying dysentery in Calcutta. The aim of this valuable work is to differentiate the two great classes of dysentery—amœbic and bacillary—in their pathological and clinical aspects, and to give the necessary indications for their successful treatment. In this connexion it deserves special mention that the author during his investigations was fortunate enough to discover the rapid specific action of the hypodermic injection of the soluble salts of emetine in the amœbic form of dysentery. There can be little doubt that this discovery enhances greatly the importance of distinguishing between the two varieties of the disease—namely, that caused by amœbæ and that by bacilli; and for this reason alone the publication of this volume would have been opportune. It has long been recognised how difficult it was to treat chronic amœbic dysentery by the use of ipecacuanha, but there are now reasons for believing that in the emetine treatment we have a permanent as well as a rapid means of curing this very serious disease.

The author first of all gives a history of the evolution of our knowledge of dysenteries, and then discusses the epidemiology of the malady. The dysenteric amœbæ and their differentiation from harmless intestinal forms are then considered, after which the pathological anatomy, the clinical symptoms, and the treatment of amœbic dysentery are fully dealt with. The chapter devoted to the consideration of the remote complications of amœbic dysentery occupies about one-third of the whole book, and deals more particularly with the very important subject of suppurative amœbic hepatitis or tropical abscess of the liver. This chapter, we understand, is really an article on amœbic abscess of the liver which appeared in the second edition of Major Rogers's work on "Fevers in the Tropics." This article has been revised for the volume now under review, and has been transferred permanently to it. In consequence it will be omitted from any future issue of "Fevers in the Tropics." It need hardly be stated that the author has dealt with the subject of liver abscess in a very complete manner, going fully into the diagnosis and treatment, operative and other, of this affection. In the succeeding chapters bacillary dysentery, its etiology, bacteriology, pathological anatomy, clinical characters, and treatment receive due attention, and other forms of the disease, including that due to balantidium coli and the relation of intestinal worms to dysentery, are discussed. Lastly, "hill diarrhœa" and "diarrhœa alba," or sprue, are described, and indications for treatment suggested.

The volume is altogether interesting; it is written in a clear and concise style which fixes the attention of the reader. We heartily recommend the book to all those who are seeking for information or guidance on the subject of dysentery.

Therapeutics of the Gastro-Intestinal Tract. By Dr. CARL WEGELE. Adapted and Edited, with Additions on the Diagnosis of the Diseases of the Œsophagus, Diagnosis of the Diseases of the Gastro-intestinal Tract, Duodenal Tube and its Uses, Diseases of the Pancreas, and X Ray Examinations of the Gastro-intestinal Tract, by MAURICE H. GROSS, M.D., Attending Gastro-Enterologist to the Har Moriah Hospital; and I. W. HELD, M.D., Attending Physician to the Har Moriah Hospital. With 52 illustrations in the text and 2 figures in colours on one plate. London: Rebman, Limited. Pp. 329. Price 12*s.* 6*d.* net.

THE reasons given by the editors for presenting Dr. Wegele's book in English guise are "because it comprises, in short systematic arrangement, many important facts which are scattered in specialised works too exhaustive for the busy practitioner; because, rightly according to the Editors' views, it lays main stress upon and consistently carries out the dietetic, physical, and hygienic treatment of gastro-intestinal diseases." We have already reviewed the original German edition in some detail in these columns,[1] and expressed the opinion that Dr. Wegele's book is an important addition to the literature of digestive diseases and a valuable work of reference. We said that it is thoroughly modern, and expressed our gratification that it contained more references to English and American monographs and papers than was usual in German text-books. We noted also the exhaustive and instructive manner in which the treatment of the conditions with which the book is concerned is dealt with, its recommendations having usually a personal basis. Naturally, these remarks apply also to the subject matter of the present work, in so far as it is a translation, and we may add that the translation appears to be well done and free from the disfigurement of foreign expressions dressed in English words, which is a not infrequent characteristic of translations.

As regards the editors' additions and condensations, they carry the *imprimatur* of Dr. Wegele himself in a brief prefatory note, and undoubtedly add to the value of the book. Our opinion of the original being so favourable we are naturally glad to welcome its appearance in an English dress.

Der Normale Menstruelle Zyklus der Uterusschleimhaut. With 25 figures in 20 plates. By Dr. med. ROBERT SCHROEDER, I. Assistenzarzt der Universitäts-Frauenklinik zu Rostock. Berlin: August Hirschwald. 1913. Pp. 15 text. Price M.16.

FOR the proper study of the pathological changes which may arise in the mucous membrane of the body and of the neck of the uterus it is obvious that we should have a very clear conception of the changes in the endometrium which normally occur in connexion with menstruation. A great deal

[1] THE LANCET, Dec. 2nd, 1911, p. 1561.

of the confusion which still prevails in the writings of many gynæcologists on the subject of so-called endometritis is due to the fact that they have not taken the trouble to control their pathological studies with observations on the certainly healthy endometrium. Recent observations have tended to throw a great deal of doubt on many cases of supposed endometritis, and a study of the very marked changes which the healthy mucosa undergoes during the varying phases of menstruation has served to show that they may very closely resemble apparently pathological states.

In this monograph Dr. Robert Schroeder has carried out a very painstaking study of a large amount of material with a view to determining the exact changes in the uterine mucosa during the varying phases of menstruation. He finds it possible to divide his cases into seven different stages—namely, those belonging to the beginning and the end of the premenstrual and postmenstrual periods respectively, and those corresponding not only to the beginning and end but also to the middle of the intermenstrual interval. His observations are of great interest, and particularly those concerned with the presence of round cells and plasma cells in the normal mucosa. He concludes that it is only when round cells are present in definite numbers and masses that they can be considered as evidence of an inflammatory process, and in the same way the presence of a few plasma cells is by no means proof of a precedent inflammation; to prove this they must be present in some numbers. The fact that at the end of the premenstrual period polynuclear leucocytes are often found in considerable numbers is very interesting in this connexion.

The work is illustrated by a fine series well reproduced of 25 coloured illustrations in 20 plates. The whole constitutes a valuable piece of research and should prove of great service as a series of control observations for those workers interested in the subject of endometritis.

Ueber Nervöse Erkrankungen nach Eisenbahnunfällen, mit Besonderer Berücksichtigung ihrer Beeinflussung durch Kapitalabfindung bezw. Rentenverfahren. By Dr. med. PAUL HORN in Bonn. Mit einem Vorwort von Dr. Th. RUMPF, geh. Med.-Rat und Professor an der Universität Bonn. Bonn: A. Marcus und E. Weber. 1913. Pp. 152. Price, paper, 4 marks; bound, 4.80 marks.

IN an unusually interesting and instructive brochure Dr. Horn has published the results of the investigation of some 173 cases of traumatic neurosis following on railway accidents. He has observed the cases over varying periods, and is in a position to state the results of treatment and of compensation or otherwise, in some cases a number of years after the accident. Details as to compensation have been supplied by the authorities of the railway system with which Dr. Horn is concerned. Of the 173 cases 136 received compensation by payment of a round sum down, while 31 are obtaining so much a week until they reach a certain age, or for a certain length of time. Analysis of these two classes leads to the following remarkable result: of the 136 whose compensation consisted in the payment of a round sum no fewer than 81 per cent. of such as were paid within one year after the accident are cured, while 45 per cent. of those who were paid a lump sum within two years are cured, and 25 per cent. of those who were paid within three years are also cured. Evidently the longer the interval between the accident and the settling of the compensation claims, the less high is the percentage of recoveries. But of the 31 in receipt of continuing weekly or monthly compensation only 2 have improved, while 27 remain absolutely *in statu quo*, and 2 are worse. These figures are very suggestive. Dr. Horn shows conclusively that between the two groups there are no material differences as to type of accident or nervous predisposition. Further, after an interval of six years from the accident only 11·7 per cent. of the first group show nervous symptoms, while no less than 77·5 per cent. of the second group still complain of typical traumatic neurosis.

There is much more of interest for the neurologist and medical jurist in this well-written brochure, and we commend it heartily to the notice of all who are concerned with the problems that are here discussed.

Outlines of Psychiatry. By WILLIAM A. WHITE, M.D., Superintendent, Government Hospital for the Insane, Washington, D.C., &c. Fourth edition, revised and enlarged. Nervous and Mental Monograph Series, No. 1. New York: The Journal of Nervous and Mental Disease Publishing Company. 1913. Pp. 318. Price 3.00.

WE have already favourably noticed previous editions of this textbook of psychiatry, which is now in a fourth edition and has been considerably enlarged, mostly by the addition of extracts from case records as illustrative of various mental diseases and syndromes. The whole forms a concise compendium of psychiatry, thoroughly modern in spirit and nomenclature, and we consider it eminently calculated to serve the purposes of student and practitioner. It does not pretend to be exhaustive or critical; at the same time it contains numerous references to the literature on any points that require fuller consideration than the scope of the book will allow. This new edition concludes with a chapter on the Binet-Simon scale for measuring intelligence, which will be found extremely useful.

LIBRARY TABLE.

Gout, its Etiology, Pathology, and Treatment. By JAMES LINDSAY, M.D. Edin., M.R.C.P. Lond., Honorary Physician, Royal Mineral Water Hospital, Bath. London: Henry Frowde and Hodder and Stoughton. 1913. Pp. 212. Price 5*s.*—In this small volume Dr. Lindsay records the results of his observations on about 600 cases of gout. He expresses himself in simple but explicit terms, and his views are interesting and suggestive. He lays considerable stress on the hereditary nature of gout, and believes it to be present in all who spring from a gouty stock. He thinks that this diathesis, if sufficiently strongly marked, may manifest itself in the form of gout without the aid of other factors, but that, on the other hand, it may lie dormant until such time as the accumulative forces of other factors are also brought into action. In considering the bacteriological theories of gout Dr. Lindsay discusses the present-day attitude of observers—namely, that gout is due to various toxins circulating in the blood and present in the fluids of the body, these toxins being the outcome of certain faults in metabolism originating in an altered condition of the gastro-intestinal digestive processes. He appears, however, disinclined to accept the evidence so far brought forward as to the rôle played by the streptococci which have been described as occurring in the large intestine in gouty individuals. The remarks on treatment are well worthy of perusal, especially those relating to mineral water and spa treatment.

Mental Self Help, a Practical Handbook. By EDWIN L. ASH, M.D. Lond. London: Mills and Boon. 1913. Pp. 170. Price 2*s.* 6*d.* net—This little book is intended to be put into the hands of the psychically ill, who will thereby, it is hoped, make use of psychic influences for themselves and work out their own salvation. Lengthy directions are given as to the use of auto-suggestion and self-mental development. No doubt much of the advice herein contained is excellent, but we feel that something more than an appeal to mere reason, something more than a cold "I will attain harmony of mind and body," is required if the sufferer is to be influenced in the desired direction. We miss any exposition of the

emotional or affective dynamic—that which makes an idea living and fertile—without which appeals to the intellect or reason are not calculated to attain any momentum.

A Survey of the Woman Movement. By ROSA MAYREDER Translated from the German by HERMAN SCHEFFHAUER. London: William Heinemann. 1913. Pp. 275. Price 5*s.* net.—This book is remarkable for its breadth of thought and impartial outlook, and were it not handicapped by the fact that it demands of its readers close and hard thinking it would be found in the hands of all who are interested in the Woman Movement, whether sympathetic, indifferent, or antagonistic. In the preface the author states that although she is not in sympathy with all the aspects of the Woman Movement she regards it as a phenomenon which distinguishes it from previous periods of history, and forms one of the finest manifestations of this epoch. She limits herself to the discussion of the ethico-psychological aspect of the subject. She realises at the outset that her presentation of the facts will not appeal to all, for people of radically different temperaments cannot come to any understanding by intellectual means. The first chapter contains numerous quotations from eminent writers exemplifying the complete discordance and contradictions of their published opinions and definitions of the essential factors of "woman" and "true womanliness." These pages form amusing and highly instructive reading. The chapter on masculinity deserves close study. The attributes of masculinity or primitive manhood are discussed in relation to the scope available for their exercise in a civilised community. It is shown how the gradual advance of civilisation has narrowed the sphere of the primitive masculinity until the paradoxical conclusion is reached "that through civilisation ..... man himself labours to bring about the destruction of his masculinity." The poignant condemnation of the deficient education of boys with its disastrous effects upon their future happiness merits the careful consideration of all teachers and parents (pp. 121–123). The various living types of women are described with considerable skill and contrasted with the ideal of womanhood as erected in literature. Although the chapter dealing with the various feminine personalities, and also that on the "Strong Hand," which analyses the types of men, demand very concentrated attention on the part of the reader, they will amply repay the trouble. "Nothing," says Rosa Mayreder, "is so significant as the air of infallible certainty which men assume in their generalisations about women, even those men who, in their attitudes to all other phenomena in the realm of experience, preserve the most careful and conscientious reticence of thought. ..... Woman and woman are no more alike than man and man. Unless this fundamental truth is recognised, the psychology of sex will remain a labyrinth of insoluble contradictions." The dissociation of the personality and the lack of harmony visible in both men and women whose temperaments clash with their experiences in love or other close association with the other sex are worked out in these chapters, and the conclusions arrived at are detailed in the succeeding pages, which deal with "the subjective fetich of sex" and "vistas of personality." Individuals are divided by the author into acratic and synthetic personalities—the former including the majority who are unable to pass beyond the barriers of sex, having no capacity to understand or enjoy the good fellowship and friendship which exist between the synthetic type of men and women. The ideal of the mate, the equal comradeship in love, is that to which human marriage is tending, as only in that form of love is possible the complete harmony of the individual, spiritual and physical. Both ancient and modern authors are quoted throughout the book in support of the thesis advanced as to the future harmony of the free man and the free woman. But the picture of the happy harmony dimly outlined in the concluding chapter of "The Woman Movement" has been portrayed with more vivid reality in many of George Meredith's books, but perhaps nowhere more prophetically than in "Diana of the Crossways": "With her ..... he understood the right union of men and women from the roots to the flowering heights of that rare graft. She gave him comprehension of the meaning of love—a word in many mouths, not often explained. With her, wound in his idea of her, he perceived it to signify a new start in existence, a finer shoot of the tree stoutly planted in good gross earth; the senses running their live sap, and the minds companioned, and the spirits made one by the whole-natured conjunction. In sooth, a happy prospect for the sons and daughters of Earth, divinely indicating more than happiness: the speeding of us, compact of what we are, between the ascetic rocks and the sensual whirlpools, to the creation of certain nobler races, now only dimly imagined."

Geburtshilfliches Vademekum fur Studierende und Aertze. By Professor Dr. A. DÜHRSSEN, Berlin. Tenth enlarged edition. With 43 illustrations. Berlin: S. Karger. 1913. Pp. 308. Price 5.60 marks.—There is little need to say more of Dr. Dührssen's work on obstetrics than that it has reached its tenth edition and is widely read by, and well known to, foreign students. The book has been translated into five languages. This edition has been carefully revised and considerable additions have been made to the sections dealing with incision of the cervix, vaginal Cæsarean section, and extraperitoneal Cæsarean section.

Labour Room Clinics. Being Aids to Midwifery Practice. By V. B. GREEN-ARMYTAGE, M.D., Captain, I.M.S., Resident Surgeon, Eden Hospital, Calcutta. Calcutta: Thacker, Spink, and Co. 1913. Pp. 67. Price 2*s.* 6*d.* net.—Captain Green-Armytage in his little book gives a *résumé* of the principles of the teaching and practice of obstetric medicine at the Eden Hospital, Calcutta. The contents consist mainly of a classified series of notes and of answers to questions. The teaching is such as is given in the best maternity hospitals in this country, modified to some extent so as to be of the greatest possible value to students and practitioners in India. The book should prove very useful to those for whom it is written. The text is well arranged and evidently based upon a considerable experience.

Maternity Nursing. By SARAH MACDONALD, Matron of the Salford Maternity Training School and Private Nursing Home. With 11 diagrams. London: Methuen and Co. Pp. 201. Price 3*s.* 6*d.* net.—Miss Macdonald has described very clearly and simply in her little book all the facts that should be in the possession of a monthly nurse. The book is a happy combination of theory and practice, and is full of sound common-sense and good advice. The breezy style of the authoress is well exemplified in the concluding paragraphs of the book, in which she points out to her readers her conception of their duties as nurses. "You are *out* to fight cancer. You are *out* for the cause of the great unborn. You are *out* for the cause of the women who go through the 'valley of the shadow.' You are *out* for the children who are to be the future citizens of our Empire." A book we can recommend.

DONATIONS AND BEQUESTS.—By the will of Mr. C. Taylor, of Brampton, Cumberland, the Cumberland Infirmary will receive £4000, the Home and Sanatorium for Consumptives, Threlkeld, £2000, and the Carlisle Home for Incurables and the Silloth Convalescent Institution £1000 each.

THE LANCET.

LONDON: SATURDAY, OCTOBER 4, 1913.

The Opening of the Medical Session.

THE medical schools of the country for the most part commenced their October session this week, and have done so in every case with a certainty that they are carrying on a more strenuous and, if possible, a more valuable work than they have hitherto done. The responsibilities of those in whose hands the training of our young men lies are now truly vast, and the association of medicine in every direction with daily life has notably increased these responsibilities. Medicine, on the one hand, sees to-day far greater chances of a practical outcome to its academic teaching; and the public, on the other hand, perceives more often and more justly how imperative it is that sound political economy and sound medicine should be in accord. The vast modern changes in medicine, whether we think of its scientific aspects, its social relations, or the material well-being of those who live by its practice, must all alike be reflected in the energies of the medical school, and these energies have consequently to be displayed to the accompaniment of an unusual stress of circumstances. Without entering upon a repetition, which would indeed be monotonous, of the various definite directions in which medicine (including in the word, of course, surgery) has taken famous strides forward, we must all be aware that such individual successes mean more than the cure or the relief of a certain number of sick. It would be quite possible to imagine a science which was making no substantial progress, even while here and there the elaboration of particular discoveries or the perfecting of some methods of diagnosis might give a contrary idea to the more or less casual observer. The great progress of our science is not confined to sporadic triumphs, however magnificent; it is taking place all along the line in a far more imposing and beneficent manner, by associating itself in every direction with the grand developments of natural philosophy which accompanied the dawn of the twentieth century. Chemistry is making promises of infinite value—and we share them; no one can set bounds to the developments that are indicated in physics—as they come we shall share them. The scientific history of the future will take note of the power exercised by medicine upon racial development; the records of all peoples will include the health statistics of the community as among their most important factors; the influence of disease upon the peaceful expansion and contraction of national possessions will be treated by historians with something of the respect hitherto bestowed upon Royal misalliances or battles of wholly unfruitful issue. The limitless range of medical acquisition which is thus indicated brings its difficulties to the medical school. It is no use for the practitioner to be sound on the ether of space but inexperienced in the significance of a temperature chart; and the bio-chemistry of the princes of pathology must not be studied with any disregard for the dosology of calomel. In other words, the scope of medical education is now infinitely large, but the daily routine of the medical school must continue to some extent as of old. The rudiments must be faithfully learned and the accepted knowledge must be accurately acquired; the difference in medical education will gradually appear in the full feeling among teachers and taught that they are engaged not in the study of a section of natural philosophy, but of natural philosophy itself.

This spirit is well reflected both in the addresses which have been delivered by certain of the orators at the opening of the schools and in the personalities of those orators themselves. There was a time when the introductory address at a medical school was largely of one pattern. Admirable examples of public speaking as many of them have been, they consisted for the most part in the expression of opinion by a member of a staff of a hospital that the new students, to whom he more or less confined his words, were to be congratulated upon their choice of a noble profession, and would find as a reward for any industry which they displayed the satisfaction of being able to do good work for the benefit of their generation. The ideas of the orators were bounded by the horizon of medicine at the time, and excellent words of wisdom were spoken by them. The new conceptions of medicine are well illustrated by such addresses as that of Director-General Sir PARDEY LUKIS at the London School of Medicine for Women, which we comment upon in another article, that of Sir JOHN PRESCOTT HEWETT, at the school of St. Mary's Hospital, and that of Mr. SAMPSON HANDLEY, at the school of the Middlesex Hospital. Professor ARTHUR KEITH, again, at the University of Birmingham, will be sure to display with emphasis and eloquence the study of anatomy as the key to the origin of the modern races of the world. The two high Indian officials, from different points of view, introduce the sanitary needs of the Indian empire to English medical schools as a matter that deeply concerns the medical work of the present and future; in other words, they recognise that it is in the power of the medical profession to influence enormously for good the national and political future of the whole empire. Mr. HANDLEY goes so far as to invite ambitious young men to qualify in medicine so as to fit themselves for political work and public service. We are not quite in accord with this extravagant suggestion—perhaps not seriously made—for it is not distinguished renegades that we want to cultivate, but medical men who, while having their professional knowledge at their fingers' tips, possess also the breadth of outlook enabling them to take full advantage of the proffers of coöperation and the requests for assistance that will reach them in increasing quantities from the public. All the three addresses which we publish in THE LANCET this week are directed to an audience interested in humanity at large, and not specially to the new students in medicine.

It is pertinent to ask whether the large and philosophic view

of the calling of medicine now taken by all who think deeply on the subject makes any alteration in the material prospects of the medical practitioner. In our opinion all the indications are towards the enjoyment by the medical profession of a greater prestige and a fuller power of expansion in the time ahead of us. We believe that the ranks of medicine will be recruited in the near future by men of as high scientific promise as ever, and possibly the recruiting will be larger; and we believe also that the whole level of general practice will be raised by the association of all its practitioners in some orderly manner with the developments of any branch of any science whence medical contributions are required. We are aware both of the bitterness of the struggle through which medical practitioners have recently passed, and, moreover, that that struggle is not yet past; but the fact that the material damage done to the medical profession has been counterbalanced by certain recognised advantages will prevent any disastrous numerical deficiency in our ranks, while all the signs of the times encourage us to believe that the approaching years will find the exponents of our knowledge, craft, and art in leading positions in the councils of the nations.

Malingering under the National Insurance Act and Medical Referees.

THE dissatisfaction of the Friendly Societies with the financial situation brought about by their expenditure upon medical benefits since the National Insurance Act has been in force took the form of a resolution at the National Conference of Friendly Societies[1] that the administration of medical benefits under the Act should be transferred to the Approved Societies. Apart from a transfer, which we think will not, and which we are certain ought not, to take place, the appointment of medical referees is the principal remedy suggested for the checking of an evil which no doubt exists, and which must at any rate contribute to the expenditure due to sickness to an extent which the Friendly Societies regard as unnecessary. The amount of malingering in existence is in question, and it is difficult to see how we can know the extent of the evil until some steps to remedy it are taken. Undoubtedly the checking of malingering presents grave difficulties, and the fearless and intelligent use of medical referees should do something to control it, but that it will restore the expenditure upon sickness to a point satisfactory to the managing bodies of Friendly Societies is not to be anticipated. They have always stood for thrift, but in the past their most obvious economy was at the expense of members of the medical profession, and the attitude of their own members towards the medical attendance and medical benefit provided by the Insurance Act is now the cause of the drain upon their funds of which they complain. It is not the fault of the medical men upon the panels that patients seek their aid, but it would be surprising that they should do so if that aid, when given, were of the character recited in one of the motions before the National Conference of Friendly Societies. Reference to it will show that it assumed "an excessive expenditure on medical benefit and the inadequate and unsatisfactory service obtained therefor," but in the discussion which took place this view was not accepted unanimously, and Brother STANTON, of the Rechabites, made an awkwardly unanswerable point when he observed that "whilst delegates in conference were saying one thing, their members were running to the doctors as fast as their legs could carry them. It was not the members who were saying that the medical service was unsatisfactory, but the officers of the society, because it was costing so much in proportion to what it did before." Brother STANTON'S words should be seriously considered by advocates of the administration of medical benefits by Approved Societies, who utter vague threats as to their power to restore the old order through the weight of the votes at their back. It is by no means certain that the votes of their own members would support them in their desire to restore medical attendance to its former position under the Friendly Societies.

What amount of malingering exists, as we have said, is doubtful, but the employment of medical referees seems a necessary preliminary for dealing with the question. Malingering is a form of fraudulent imposture which legislation for the benefit of the working classes has already increased through the Workmen's Compensation Acts, and which honest working men must desire to see detected and, if possible, punished. It must be conceded by all that the position of a medical referee appointed with the admitted object of checking expenditure upon sickness under the Insurance Act will be one of difficulty and of responsibility, and one which will only be adequately filled by a medical man who has the confidence of members of his own profession on account of his undoubted qualifications for the post which he will occupy. In the performance of his duties he will have to smooth his own way as well as that of others by the exercise of tact, but he will have at the same time to be a strong man occupying a strong position. These considerations have the double significance which is so eternally embarrassing. They point to the advisability of the medical referee being a whole-time official, remunerated by a salary which will attract a good man to the post, and employed under conditions which will ensure the independence of his actions and decisions. But they point to the necessity of selecting only a man who has first-hand knowledge of the difficulties of practice among the poor, and who is also a sound and seasoned clinician. Even then too much must not be expected from the medical referees, particularly as regards financial results. Their salaries and expenses will absorb an appreciable part of the economies which they will effect, if those salaries and expenses are to be defrayed from the funds which it is desired to protect. The public value of the appointments will depend, firstly, upon ascertaining how far malingering, justly so called, is responsible for the expenditure complained of. The expenditure on ailments formerly untreated (which is in some quarters particularly resented in the case of women) is not due to "malingering," even though no medical treatment was sought before the Act. And, again, though malingering may probably be the cause of a great deal of

[1] THE LANCET, Sept. 27th, 1913, p. 969.

unnecessary expenditure, it has yet to be ascertained that it can be brought so promptly and so generally to the notice of medical referees that they will be able to check it entirely, or almost entirely. Medical referees, moreover, will not be infallible in their judgments, any more than those medical men whose patients they may be called on to examine, and the temptation to malinger provided by the Act will remain as before.

A Women's Medical Service in India.

WE publish in another column the admirable address on the Medical Needs of India, which was delivered at the London School of Medicine for Women on the opening of the October session by Surgeon-General Sir CHARLES PARDEY LUKIS, Director-General of the Indian Medical Service. In the course of his address Sir PARDEY LUKIS, having dwelt upon the absolute necessity of the education of the Indian people in personal and domestic hygiene, as being the only way to lessen the dangers incidental to childbirth, to mitigate the horrors of a gross infantile mortality, and to remedy the sanitary defects owing to whose presence both plague and malaria are alike prevalent, comes to the essential fact that until the women of India are convinced as to the necessity of personal hygiene the root of all these evils cannot be reached. The only way at present of educating the people of India in the laws of personal hygiene is to rely on the magnificent efforts of the Indian Medical Service, of certain medical practitioners in India, of lecturers in association with the St. John Ambulance Association, and of missionaries. All these already discharge the duty of inculcating the principles of right sanitary living upon the populace, but unfortunately *purdah* intervenes, and only the male population of the empire can in this way be reached. Here Sir PARDEY LUKIS makes a significant statement, and one on which the whole of the scheme for a Women's Medical Service in India depends. He points out—and the information will be quite startling to many of us—that in the Indian home the wife and the mother are paramount authorities. So that, once let the women of the household be convinced that this, that, or the other proceeding is healthful and wise, reform will follow; but until this persuasion of the women can be achieved Sir PARDEY LUKIS thinks, speaking with an experience to which we willingly defer, that attempts to raise the standard of public health in India, to eradicate conditions leading to epidemic disasters, and to prevent the sacrifice of life now due to accidents of childbirth and infant mortality, will each and all be wasted to a considerable extent.

For the urgent needs of India at the present time an adequate supply of suitable and fully trained medical women is required, and Sir PARDEY LUKIS has exhibited to the London School of Medicine for Women the well-covered skeleton of a service designed to meet the existing position. The work both of missionary societies and of the Lady Dufferin Association, extraordinarily valuable and self-sacrificing as it has been, cannot pretend to cope with the conditions, and in particular the legitimate grievances of the medical women serving under the Lady Dufferin Association are admitted to require removal if recruiting for the association is to go on. The scheme outlined for a service to be called a Women's Medical Service in India shows in the first place careful provision for the selection of a small staff of 25 first-class medical women. Recruitment for the service will be made in two ways. In India a medical subcommittee of the Central Committee, including the Director-General of the Indian Medical Service, the surgeon to the Viceroy (who is *ex-officio* the honorary secretary to the Central Committee), and a first-class medical woman will select the candidates; in England a subcommittee consisting of a medical man and two medical women conversant with Indian conditions, to be nominated by the Home Committee of the Dufferin Association, will incur similar responsibility. In this way candidates will be properly examined for physical fitness, and it is provided that in the original constitution of the service duly qualified medical women who are already in the service of, or who have rendered approved service to, the Dufferin Association will have first claim to appointment; while thereafter special consideration will be paid to the claims of candidates who have qualified in local institutions and of those who are natives of India. The suggested terms of the new service are, we think, good. If it is objected that they do not err on the side of generosity, we have to remember two things: the first is that medical appointments, whether for men or for women, and whether at home or abroad, are seldom instituted on any but economical lines; the second is that the probationers of the new service will not be of any very great value to the scheme in its larger aspects during the early periods of their office. The whole service is instituted with the definite idea of getting into close touch with the domestic life of the native, and for this a knowledge of Indian ideas, standards, and traditions is absolutely required, and ability to converse adequately, if not fluently, in some of the languages of the country will be an advantage so extensive as to become almost a necessity. The terms of service are stated with considerable detail by Sir PARDEY LUKIS, and we refer our readers to them, but it will be seen that the salaries, which rise from R.350 per mensem to R.550 per mensem, will be supplemented by the provision of suitable quarters rent free, or by house rent in lieu, while travelling expenses at the usual rates can be drawn, and in addition to the usual privilege leave, eight months' furlough after four years' service will be granted, and study leave up to nine months. There will also be permission to engage in private practice so long as the performance of official duties is not encroached upon.

Lastly, there will be a provident fund as a provision for retirement. The rules of the provident fund are not yet formulated, but we are authorised to state that this fund will be contributed to separately from the pay of the members of the service, and not formed solely by deductions from salary. It may be taken for granted that whatever the members of the service put into the fund the Lady Dufferin Association will add an equal amount, and the whole will accumulate at compound interest until resignation. The proper amount of the contributions, the question of

their forfeiture in cases of discharge for misconduct, the rates of interest and other details remain to be settled; but in the meantime we may point out that such a provident fund presents a flexibility that no pension scheme would possess. This fact is worth noting in the case of young women, who in the event of marriage would be able, with a short reasonable notice, to obtain their accumulated dues.

Annotations.

"Ne quid nimis."

PASSENGER SHIPS AND SMALL-POX.

THE Corporation of the City of London have recently drawn the attention of the Local Government Board to the risks of introduction of small-pox into this country through the Port of London. Many vessels arrive in the port within 14 days of their departure from ports at which small-pox is known or suspected to be occurring, and the corporation asked that the medical officers of health of port sanitary authorities should be empowered to inspect all persons on such vessels, to require them to give their names and addresses, and to detain on board any person whose address was considered unsatisfactory, suitable penalties being prescribed for non-compliance. The Local Government Board are reported to have replied that they did not consider, on the evidence before them, that they would be justified in adopting the course suggested, and the corporation in expressing regret at this decision have stated that in their opinion a serious loophole exists by which it is possible for small-pox to be introduced into this country. The possible introduction of small-pox in these circumstances cannot be denied, and the zeal of the City authorities, which is doubtless to be attributed to their apprehension of the results of the increasing neglect of vaccination, is to be commended. But it must be admitted that there are serious practical objections to their proposals. Although port medical officers of health cannot examine and detain passengers simply because the ship has come from a port in which small-pox is believed to be present, they can already offer vaccination and put in force measures of isolation and disinfection when the ship has had a case of small-pox on board or during the voyage, and they can also in these circumstances apply various other powers possessed by a medical officer of health on shore. But if the proposed new duties are to be added, and the work is to be done thoroughly, a large expense must be incurred in providing additional officers to undertake an irksome form of medical service, while the travelling public would be subjected to an amount of interference and inconvenience which ought not to be imposed without very strong evidence of necessity. Those who would put their main reliance on frontier action for keeping out small-pox would do well to study the recent experience of small-pox in Australia. In that country, where strict measures of exclusion are applied, the ports are few, the distances which have been travelled by the incoming vessels are long, and the conditions for securing defence by quarantine are almost ideal.

A PUBLIC HEALTH DISPUTE AT ARBROATH.

AS a result of a considerable epidemic of scarlet fever in the town of Arbroath the hospital for infectious diseases became full, and the public health committee of the town council, in order to make some provision for the isolation and treatment of cases at their homes, decided to engage a visiting nurse or nurses who, when desired, were to undertake eucalyptus inunction and other proceedings adopted in what is known as the "Milne method." The medical officer of health, Dr. A. D. Yule, was instructed to circularise medical men in the district on the subject, but in the circular which he issued no reference was made to the "Milne method." His action in so doing was severely criticised at a meeting of the town council specially called to consider the matter, at which it was decided by large majorities that the intentions of the council should now be expressed to medical men and the public by the town clerk, and that the approval of the Local Government Board for Scotland should be asked to the nurse or nurses acting independently of the medical officer of health when requested by any medical practitioner in the town or by a guardian of a scarlet fever patient. A report in the *Dundee Advertiser*, from which our information is obtained, shows that Dr. Yule justified his refusal to carry out the wishes of the council on the grounds, first, that it was his duty to his medical friends not to attempt to impose any particular form of treatment on them; secondly, that the form of treatment to be offered was a medical question on which the town council had no right to dictate to him; and thirdly, that he was not willing to carry out the "Milne treatment" in Arbroath. The first of these arguments seems less strong than the other two. The public health committee does not seem to have wished him to do more than to supply facilities for treatment to such medical men as chose to avail themselves of them, and the committee may reasonably reply that medical officers of health make no such difficulties in other circumstances, such as the treatment of diphtheria by antitoxin, where facilities for treatment are afforded out of public funds. The root of the matter, however, seems to lie in the fact that the treatment which the committee desires to be supplied is one in the efficacy of which the medical officer of health disbelieves, and for which, on medical grounds, he feels unable to take responsibility. In these circumstances the town council has no more justification for objecting to his action than it would have if the town clerk advised that an agreement which it wished to make was illegal, or if its engineer reported that he considered the design of a bridge was unsafe. The views of the Local Government Board on the matter will be awaited with interest, and we would be surprised if that body were to give any decision which would discourage the expert officers of local authorities from fearlessly acting up to the opinions which they have formed, to the best of their ability, on the technical matters which fall within their province.

BOSSUET AS ANATOMIST AND PHYSIOLOGIST.

To the majority of our countrymen we fear that Bossuet is little more than a name, though most students of literature are probably acquainted with his Oraisons Funèbres as examples of "the grand style" in preaching, for which they were remarkable even in that century of sermons, the seventeenth. Few know, however, that amid the cares of the oversight of the diocese of Meaux he found time to write some 50 works chiefly dealing with philosophy, religion, the condition of the Church, and various controversial matters. One of his most noteworthy though little known treatises is that entitled "De la Connaissance de Dieu et de Soi-Même," written for the instruction of the Dauphin, afterwards Louis XV., an interesting critique and epitome of which has recently appeared from the pen of Dr. A.-F. Le Double of Tours.[1] The thesis which Bossuet set himself to defend was to show that the knowledge of God must be preceded by a knowledge of ourselves. To know ourselves we must grasp the fact that there are two parts in man, the soul and the body. These must first be considered singly and then as united.

[1] Bossuet, Anatomiste et Physiologiste. Par M. le Professeur A.-F. Le Double. Paris: Vigot Frères. 1913. Pp. 301. Price 5 francs.

From the consideration of soul and body we rise to the consideration of God, who is the cause and end of both. The treatise concludes with a chapter on the difference between man and beast. In his chapter on the body Bossuet gives a very fairly complete account of the anatomy and physiology of the different organs, though naturally the errors prevalent at the time appear in his descriptions. On the whole, however, the account is worthy of his teachers and friends, Duverney, Stenon, and Winslow. Dr. Le Double, despite his admiration for Bossuet's treatise, has no hesitation in pointing out the errors, and a large portion of his first chapter is devoted to them, and is illustrated by historical notes. The remainder of the work is mostly occupied by an examination of Bossuet's psycho-physiological views. As regards the general problem of his thesis Bossuet was naturally a teleologist; he says, for example, in his fourth chapter, "Whoever shall understand man will see that he is a work of noble design which could neither be conceived nor carried out other than by a profound intelligence." His end, says Dr. Le Double, was to reconcile dogma, reason, and science, to grasp the Infinite and the eternal by the study of the Finite and the mortal which come under the apprehension of the senses. Whether or no he attained the goal which he had set himself to reach matters little in his opinion. "Every effort of the mind towards the unknown, or even the unknowable, is praiseworthy, whatever may be the result. The beauty of the dream is none the less because unrealised; none the less are the nobility and usefulness of the emprise." Dr. Le Double's eloquent and instructive book should tempt many towards a further study of Bossuet's original work.

PREGNANCY AND CANCER OF THE CERVIX UTERI.

CARCINOMA of the cervix complicating pregnancy is naturally a somewhat rare disease, and its frequency has been estimated at about 1 case in 2000 cases of labour. When the conditions existing in an advanced case of this kind are taken into account it is not surprising that such cases are infrequent; indeed, it is strange that pregnancy should ever occur. As might be expected, the patients on the average are of a younger age than those in whom carcinoma alone is present, but that it may occur in a patient as old as 40 is shown by the interesting case of this kind recorded in THE LANCET of Sept. 27th, p. 930, by Mr. H. B. Mylvaganam. This case is particularly interesting because the uterus was the seat of a twin pregnancy, and evidently conception had taken place after the onset of the growth. The age of the fœtuses was probably 3 months, and there was a history of a blood-stained discharge extending over a period of some eight months with several hæmorrhages from the uterus during the last three months. When pregnancy does complicate the course of a case of carcinoma of the cervix, in about 30 per cent. of the cases premature expulsion of the ovum takes place, and in only some 40 per cent. is a living child born. If pregnancy proceeds to full term there are many accidents which may occur during labour. Extensive tears of the cervix are likely to ensue, possibly involving the bladder or rectum, and rupture of the uterus has been reported in a considerable number of the cases. Even if the patient escapes the immediate dangers of delivery her death from septic poisoning is a very likely sequel. In one curious case recorded by Menzies and mentioned by Cullen, missed labour occurred, the patient finally dying some 17 months after the commencement of the pregnancy; the fœtus was found to be in a condition of fœtus compressus, the liquor amnii having been absorbed, but showed no signs of maceration. As might be anticipated, a carcinomatous growth complicating pregnancy grows with great rapidity, no doubt as a result of the marked vascularity of the uterine tissues. In the operative treatment of these cases there is still some difference of opinion, not as to the advisability of immediate operation—most obstetricians are agreed as to that—but as to the best route by which to remove the uterus. Not many years ago the operation of choice in the early months, at any rate when the growth was removable, was vaginal hysterectomy. The immediate results were much better than those of abdominal hysterectomy, and the ultimate results recorded by Olshausen were remarkably good. At the present time, however, most operators, whether the pregnancy was in the early or the later months, would prefer to remove the uterus by the extended radical operation, and the same arguments which are adduced in favour of this operation would, of course, hold good with even greater force in a case of pregnancy complicating a carcinoma of the cervix. Obviously nothing is to be gained by a preliminary emptying of the uterus if the abdominal route is followed, and the loosening of the cellular tissues which is present during pregnancy and the ease with which the ureters can be isolated in these conditions is only counterbalanced by the extra vascularity of the tissues. Among the first 500 cases of carcinoma of the cervix operated upon by Wertheim by the extended abdominal operation there were 8 cases of pregnancy, including 1 of tubal pregnancy. Of these 5 were alive and free from any recurrence five years after the operation. One died from pulmonary embolism, and 2 had a recurrence of the growth. Mr. Mylvaganam is to be congratulated upon the successful result of his operation, and a record of the ultimate fate of the patient would be of much interest.

MEDICINE IN THE ITALIAN PARLIAMENT.

THE Third Italy (writes an Italian correspondent) is agitated by an impending general election—an ordeal trying to any old constitutional country, but peculiarly so to one whose "risorgimento" is comparatively recent, with the additional aggravation of an abrupt lowering of the suffrage to include every adult who can read and write. The polling, on a day not yet officially fixed, takes place in October, and many are the forecasts as to which of the numerous parties, or rather "chiesole" (cliques), into which Italy is divided, will emerge victorious. The anticipation preponderatingly held, however, seems to be that the astute Premier, Giolitti, will retain his working majority—master as he is of electioneering tactics in which the influence of the local prefect, ever loyal to the party in power, is a factor far from negligible. One feature of the contest already in progress is the greatly increased number of candidates drawn from the medical profession. Hitherto it has been the legal calling that has furnished the majority of aspirants to a Parliamentary career. Indeed, the "avvocati," or, as a sarcastic public is fain to call them, "avvocatucci," have outnumbered all other professions in seeking and obtaining the coveted distinction of deputy. But the country has become a little weary of these loquacious gentlemen of the toga, whose eloquence has hitherto proved expensive in the inverse ratio of their experience or knowledge of public interests. It is this that explains the really remarkable number of physicians and surgeons, in consultant or in general practice, who have entered the field, cognisant as they are of the country's real desiderata, which may be summed up in Disraeli's memorable watchword in 1874, "Sanitas sanitatum omnia sanitas." Significant in this sense is the fact that it is precisely in those regions of the kingdom where the sick-rate and mortality are highest, where popular superstition invariably rises in antagonism to hygienic law, particularly in view, or in presence, of epidemic visitation, where physical degeneracy is most pronounced, causing rejection of

40 per cent. at the periodical military levy, that the medical candidatures in question are most numerous and most actively promoted. Southern Italy, notably the Neapolitan provinces and Calabria, are the regions indicated, no fewer than five medical candidates courting as many of their constituencies. Some of these gentlemen hold university chairs, besides being in consultant practice, and the question arises, How can they possibly find time to do justice to their pupils or their patients, on the one hand, and to their constituents, on the other? The answer is that what would be next to impossible in England is quite possible in Italy, where attendance in the House is by no means so frequently required, so prolonged, or so exacting as in the Mother of Parliaments. The Chamber of Deputies in Rome does not commence business till late in the afternoon, seldom before 3 P.M., and its business is invariably over in what in England would be regarded as the early evening, between 6 and 7. As a matter of fact, there have been physicians and surgeons enough in the Italian Chamber who have combined the two rôles, that of practitioner and that of Parliamentarian, to justify each and all of the many medical candidates now before the constituencies in embarking on the twofold career. Lanza, a Piedmontese consultant, honourably refused all official salary as Prime Minister on the ground that his professional honoraria sufficed for all his wants, while he found time not only to earn the said honoraria, but to lead up to the events which brought his illustrious client King Victor Emanuel in 1870 to Rome. Guido Baccelli is another of the consultants who hold a university chair and a seat in Parliament with conspicuous efficiency in both capacities. The eminent patriot and sanitary reformer, Agostino Bertani, surgeon-general in Garibaldi's revolutionary force, is yet another exemplar of the compatibility of the medical with the political career; while as to the senators who have been promoted from the Lower to the Upper House while keeping in touch as teachers and practitioners with medical science and practice their name is legion. Italy, indeed, has everything to gain by the presence in her legislature of public-spirited consultants and practitioners, who, with no ambition for office, are yet prepared to give their thought and experience to the body politic, claiming as that body does, a serious, a systematic rehabilitation, in the sanitary sense, to which no Italian with any sense of citizenship can now remain indifferent.

DEFORMITY OBSERVED TEN YEARS AFTER AN ACCIDENT.

IN the *Australasian Medical Gazette* of June 21st Dr. Max Herz has reported a remarkable case in which deformity was not observed until many years after the injury which produced it. A boy, aged 15 years, discovered one day that his left hand did not run in the long axis of the forearm but had grown at an angle towards the thumb. On examination he was well built and healthy. The left wrist was in the position of manus valga, the hand forming an angle with the forearm opening on the radial side. There was no pain or discomfort or disability. The left forearm measured ¾ inch less than the right. A history of an accident 10 years before was obtained. During a game he jumped from the roof of a shed and fell on his left hand. The wrist became slightly swollen and was painful for a few days. A skiagram revealed the cause of the deformity. The outer side of the radial epiphyseal zone had ossified prematurely, retarding growth; the ulnar side had developed into a spur, the growth of which pushed the hand into a valgus position. A disturbance of growth with resulting deformity due to injury of one side of an epiphyseal zone is not uncommon. The peculiarity in this case is the interval of ten years between the injury and the observation of the deformity. Both the boy and his parents were persons of high intelligence.

DIABETES IN INFANCY.

IT is well recognised that diabetes may occur in infancy, even at the age of a few days, but the cases are very rare. Of 6496 fatal cases of diabetes which occurred in England and Wales in the decade 1861–1870 the age was under one year in only 8. The following case, which is recorded in the *Johns Hopkins Hospital Bulletin* for September by Dr. J. H. M. Knox, is therefore of interest. A highly strung nervous woman gave birth, after a normal labour, to a female child. Two years before she had a severe attack of jaundice. The father, though in good health, limped from healed tuberculosis of the hip. There were an elder sister, aged 4 years, in good health and a brother who died at 4 months from some gastro-intestinal disorder. There was no history of malignant disease, syphilis, or diabetes in the family. The child was breast-fed but also given diluted cows' milk. At four months she had a severe attack of bronchitis, during which the urine was found to contain pus cells, which disappeared under urotropin. Several examinations during the following months showed not a trace of sugar in the urine. At five months the child was put on a malt soup mixture for some digestive disturbance. She thrived for a time and rapidly gained in weight. She was first seen by Dr. Knox at the age of seven months, when she appeared to be perfectly well, but she was taking an unusually large amount of malt soup. This was discontinued, and a simple milk mixture, containing two-thirds milk and 4 per cent. dextrimaltose, was substituted. She did well for a month and then was seen on May 26th, 1912, because she was not gaining weight. She was bright but rather irritable. Her weight was 19¾ lb. On May 30th, at the age of 8 months, she was found to have a temperature of 101° F. and a fruity odour in the breath. The urine contained between 4 and 5 per cent. of glucose and acetone. On May 31st she was put on "eiweiss" milk. Her weight had fallen to 18 lb. and her temperature was 99·4°. Under this diet the sugar in the urine fell to 1·5 per cent., but the general condition was not satisfactory, and on June 7th she was admitted into the Johns Hopkins Hospital. She apparently tired of the "eiweiss" milk, and was put on a mixture of 32 per cent. cream, albumin, and water (the mixture having a composition of 3 per cent. fat, 4 per cent. sugar, and 2 per cent. proteid). The amount of sugar in the urine rose, and a week after admission she became drowsy and increased amounts of acetone and diacetic acid were found. Sodium bicarbonate was administered, but she became more and more drowsy, comatose, and died 11 days after admission, having shown signs of pulmonary involvement. The necropsy revealed broncho-pneumonia and cloudy swelling of viscera. The pancreas was of normal size and of an iron-grey colour. The lobules were homogeneous in appearance, and here and there were small spots, apparently islands of Langerhans. On microscopic examination the lobules were seen to be separated by rather broad septa. In the interstitial tissue were many small round cells, which in some places seemed to replace the acini. The connective tissue and the islands of Langerhans were diminished in size and number. The capsule was thickened. The diabetes, therefore, appeared to be of pancreatic origin. In this case it is noteworthy that thirst and appetite were not greatly increased and that polyuria was moderate. Dr. Knox has collected 16 recorded cases of diabetes in children under the age of one year (including his own). In 3

cases the disease was noticed within a few days of birth. In half of the cases a statement was made as to the family history. In 3 it was good throughout, in 3 a grandparent or great aunt had diabetes. In 6 cases the disease seemed to have followed an injury to the nervous system. In 2 of these the infants sustained a severe fall on the head. In 2 other cases the symptoms may have been associated with injury at birth, as the labours were difficult. In 3 cases there was increased cerebral pressure from hydrocephalus, and in 1 malformation of the brain (anencephalus). In 3 cases the disease began after the giving of an unusual amount of sugar. One baby was fed on condensed milk; another was given 150 grammes of sugar and a litre of milk daily; and in the present case a litre of milk was given containing 10 per cent. of malt infusion. The majority of the cases showed the following symptoms in common. At first restlessness was noticed. This was followed by increased thirst, hunger, and secretion of urine. Loss of weight was a prominent symptom. Multiple abscesses were present in 2 cases, gangrene of the lung in 1, and a sore over the sacrum in another. At least 3 cases ended in coma. Three of the patients recovered. The majority of the more rapid cases terminated in three weeks. The prognosis is grave but not hopeless, unless the condition is present in a severe form. Treatment should be begun early and follow the lines of the treatment in adults. The carbohydrate tolerance should be determined and the sugar-content of the diet correspondingly reduced. An "oatmeal day" or days should be given at frequent intervals.

THE SANITARY INSTRUCTION OF THE PUBLIC.

ACCORDING to Dr. James Kerr, whose report as the Medical Officer for Education of the London County Council was published in our columns on April 12th, schools play only a minor part under present conditions in the dissemination of infectious diseases. Nevertheless, it must be recognised that children coming from infected homes are possible bearers of infection, even although they themselves may not be ill. The desirability of complete coöperation of parents and teachers, as well as of the general profession, with the school medical officers, therefore, is undoubtedly to be desired. But to attain this end the dissemination of knowledge is necessary, and in this we may learn something, perhaps, from Transatlantic methods. The Department of Health of Chicago distributes weekly a circular leaflet entitled the *Bulletin of the Chicago School of Sanitary Instruction*, which deals with such sanitary and hygienic matters as are for the time being of pressing import, the wording being brief, plain, forcible, and to the point, as is fitting in circulars intended for public reading. In the *Bulletin* for August 30th now before us the approaching reopening of the schools after the summer vacation has directed the attention of the Health Department to the importance of safeguarding the health of the children against infectious diseases when they reassemble, and the advice given seems sane and sound. The active assistance of all school principals and teachers is called for in the work of segregating possible infection bearers, and it is suggested that this should be the first and all-important work of the first school day. Principals are therefore recommended to see that, prior to the assembling of classes, the rooms are well aired, every window throughout the building being thrown wide open for hours before the children enter it. Reference to the health department's records of contagious diseases, which are kept on file in Chicago in the office of every school principal, is recommended, with a view to ascertaining whether any families from which pupils come have had recently reported cases of infectious disease. It is further recommended that the teacher should carefully observe each child, and should order all suspicious cases at once to an isolation room or out of doors, to await inspection by the school doctor, all cases of sore throat, eruptions of any kind, desquamation, congested watery eyes, snuffles, visibly enlarged glands or coughs being reckoned as suspicious. As an additional precaution, when the pupils have taken their seats, all those who now have, or have recently had, any sickness in their homes should be asked to stand up, when a little judicious questioning will probably make it clear whether any suspicion attaches to them as possibly coming from infected places. The coöperation of the medical profession in immediately reporting all suspicious cases, and insisting upon strict isolation until absolutely sure that all danger of infection is past, is called for; while parents are urged to comply strictly with the requirements of the sanitary authority by never sending an ailing child to school or permitting even healthy children from an infected house to mingle with other children, inasmuch as, even though themselves well, they may carry infection to others. "If," says the circular, "there be a proper measure of coöperation between the medical profession and the health department, there will be fewer small coffins to buy this fall and winter." Such circulars may indeed prove a fruitful source of public education in hygienic and sanitary matters, and in the last resort the people must be their own saviours in these matters, and to act intelligently it is essential that they should be instructed in what they ought to do. The *Bulletin* does not in its instructions fit in with any possible routine in our schools, but the principles which it has in view are those upon which our system of school inspection relies.

THE EMETIC ACTION OF DIGITALIS.

MUCH of the recent research into the action of digitalis and allied bodies has been provoked by the fact that the emetic action of the former has appeared to constitute a serious obstacle to its continued use, and many have sought diligently for some preparation of the drug which might be innocent of those baneful effects, or for an alternative medicament possessing all the virtues of digitalis but none of its vices. Most of these investigators have accepted without question the belief that digitalis is a gastric irritant, and therefore an emetic. One of the most interesting and valuable of the data revealed by the researches of Dr. R. A. Hatcher, of New York, and his colleagues was that experimental administration of the drug to animals by the intravenous method provoked vomiting, and that this effect of the drug was due to its action on the medulla, not to any direct irritation of the gastric mucosa. One of Dr. Hatcher's fellow workers, Dr. Cory Eggleston, has investigated the same matter from a clinical standpoint. Eleven cases of cardiac disease exhibiting auricular fibrillation, and four cases of chronic valvular disease with regular rhythm, received digitalis either as a tincture or as an infusion, and its emetic action was carefully studied with especial reference to its connexion with the cardiac effects of the drug (slowing of the pulse, alteration of the rhythm, and definite clinical improvement). Case records from the literature were examined along the same lines. The result of these observations is remarkably uniform. In 106 courses of digitalis treatment marked by nausea or vomiting there was clear evidence in 100, or 94 per cent., that the drug had been absorbed in quantities sufficient to produce a definite cardiac action before vomiting occurred. Another fact which is strongly antagonistic to the gastric irritant theory is brought forward by Dr. Eggleston; he quotes a number of cases in which very large single doses of digitalis (in one case 2 drachms of the tincture) were given without provoking any gastric symptoms whatever. In view of these facts he

argues that it is impossible to regard digitalis as emetic by virtue of an irritant action on the gastric mucosa; it is one of those drugs which cause vomiting by stimulation of the "vomiting centre" in the medulla. If general clinical experience should confirm this, it is a deduction of considerable importance; vomiting will be regarded not so much as an unfortunate check to the further administration of digitalis as an indication that the drug has been absorbed in adequate quantities. In the discussion which ensued upon the reading of Dr. Eggleston's paper at the Minneapolis annual meeting of the American Medical Association, Dr. Hatcher remarked that strophanthus is less emetic than digitalis for two reasons: first, it is less readily absorbed than the latter, and secondly, it possesses a smaller proportion of the emetic principle in relation to its cardiac activity.

THE RESEARCHES OF DANIEL HANBURY.

THE seventy-second session of the School of Pharmacy was inaugurated on Oct. 1st in the lecture theatre of the Pharmaceutical Society. The address was delivered by Dr. F. B. Power, Ph.D., LL.D., director of the Wellcome Research Laboratories, to whom during the proceedings Mr. E. White, President of the Pharmaceutical Society, who presided over the meeting, presented the Hanbury gold medal. Appropriately enough, Dr. Power chose as the theme of his discourse "The Influence and Development of Some of the Researches of Daniel Hanbury," for Hanbury was one of the earliest and most brilliant of the students of the school, and it is to perpetuate his memory that the medal is awarded biennially for high excellence in the prosecution and promotion of original research in the chemistry and natural history of drugs. The researches of Hanbury himself, as Dr. Power pointed out, did not include a great deal pertaining to the chemistry of drugs, but, on the other hand, historical and botanical studies had a special attraction for him, particularly in their bearing upon the history and source of drugs. The first communication made by Daniel Hanbury to the Pharmaceutical Society was entitled "On Turnsole," a product obtained from a plant indigenous to Southern Europe and the Orient. The expressed juice of this plant is at first of a dark green colour, but it speedily assumes a purple hue on exposure to the air; since Hanbury's investigations it has been shown that turnsole is used in Holland for the purpose of giving Dutch cheeses their characteristic red colour, and Dr. Power suggested that the chemistry of this product is a suitable subject for investigation, since it has been asserted that it possesses toxic properties. Other researches of Hanbury to which reference was made were those on the resin of the Norway spruce fir, on otto of rose, and on Chinese drugs. His contributions to Chinese materia medica were conducted 50 years ago and naturally involved very great difficulties on account of the little-known language and the limited facilities at that time for securing accurate information. Dr. Power made no reference to his own researches into the chemistry of drugs, the records of which form extremely valuable additions to pharmaceutical literature. He pointed out to the assembled students, however, that notwithstanding all the recorded facts and observations and the wonderful progress that had been made in recent years, the boundaries of science are constantly becoming enlarged, and with the broader view that is thus obtained the scope for effort and achievement expands. "The vast continents of Africa and Asia and the forests of South America, as well as the islands of the sea, doubtless contain among their natural resources," he said, "many thousands of plants which have never yet been touched by human hands, and a still larger number which have not as yet been named or classified. This wealth of material which Nature has provided will be sufficient to engage the attention of both the botanist and the chemist for a period of time so remotely distant that it cannot be forecast. There can, furthermore, be no doubt that the chemical study of the countless number of plants or plant products whose constituents are as yet completely unknown, will not only reveal much of scientific interest, but also principles of medicinal value which may be capable of alleviating some of the ills of mankind." The field of research is, in fact, practically unlimited, and the new Hanbury medallist is doing his share in the work of exploration.

THE HISTORICAL MEDICAL MUSEUM.

THE history of medicine is a subject which has of late years, in this country at any rate, attracted far more attention than formerly. The Royal Society of Medicine has organised a section of the History of Medicine, a section which held its first meeting on Nov. 20th, 1912, and in addition, also for the first time, a section in the same subject has formed part of the proceedings of the International Congress of Medicine which has just concluded its deliberations in London.

The history of medicine is a study of very many, and at first sight of widely divergent, matters, and the ideal medical historian would be a man of encyclopædic knowledge. He should know Greek, Latin, and Arabic, to mention only the three principal languages, as well as his own tongue. He should have a knowledge of palæography, be an accomplished physician and surgeon, have a knowledge of ecclesiastical history and the lives of the saints, and in addition be no stranger to anthropology and folklore; for the history of medicine is a part, and no mean part, of the history of human intellect and of search into the two great mysteries of life and death. Primitive medicine was, and is still among the few primitive races who are left, mainly concerned with amulets, charms, and incantations, i.e., songs. So in the Odyssey, when Odysseus's thigh had been ripped up by the boar, his father and brothers stanched the blood with a song, though with that practical wisdom which distinguishes the Homeric Greek they put a bandage on first:

> ὡτειλὴν δ' Ὀδυσῆος ἀμύμονος ἀντιθέοιο
> δῆσαν ἐπισταμένως, ἐπαοιδῇ δ' αἷμα κελαινὸν
> ἔσχεθον *Od. XIX. 456–8.*

Just as the study of medicine, surgery, and pathology is aided by the magnificent collection known to all as the Hunterian Museum, so a collection of articles bearing on the history of medicine is an aid to the study of that subject, and such a collection is now on view in London at 54A, Wigmore-street, a collection organised by Mr. Henry S. Wellcome and the result of some years' hard work. The museum was formally opened on June 24th, the proceedings commencing with an admirable address from Dr. Norman Moore, President of the Section of the History of Medicine in the International Congress, and attracted considerable attention from visitors to the International Medical Congress; indeed, the visitors' book would be an enviable possession for a medical autograph hunter. We have already given a short account of some of the exhibits in our issue of July 5th, but the field covered by the exhibition is so wide that we think it well to speak at greater length concerning some of the more interesting and somewhat recondite exhibits than was possible in the former article. Primitive medicine is well represented in the entrance hall by a collection of charms, fetishes, and professional dresses of medicine men from Africa. Here also are a very interesting collection of skulls showing early and prehistoric trephining. The peculiar characters of the trephine holes are noticeable for comparison with results in another case obtained by Dr. T. Wilson Parry, who trephined a number of modern skulls with prehistoric flint instruments. The correspondence of the results in the two cases is striking. There are also specimens showing the large percentage of bone disease and the prevalence of gall-stones and other

conditions among the remains found in a prehistoric Ethiopian burying ground now being excavated for Mr. Wellcome at Gebel Moya in the Sudan, as well as the method adopted for preserving the specimens.

In the central hall or Hall of Statuary (Fig. 3) are statues of deities of healing such as Ixlilton, the Mexican god of healing, Apollo, Æsculapius, Hygeia and Cheiron for Greece, Shen-Nung of China, Dhanwantari of India, Ed, Gula, Adapa and Marduk of Chaldea and Babylonia, and Thoth, I-em-Hotep and Ptah of Egypt. On the staircase leading to the gallery are three pictures of St. Luke, St. Cosmas, and St. Damian respectively. These saints are three of those connected with medicine, and tradition has it were all medical men, the first being the subject of a most interesting paper read by Miss M. Stawell at the Congress, upon which we commented in our issue of August 16th. The two latter saints are not so well known, for they were in the main Eastern saints, though as patrons of the great Medici family they obtained a certain vogue in Florence, where they are represented in numberless pictures in their doctorial robes. It is said that the medical year beginning on Oct. 1st has its origin in the fact that that is their feast day. Other saints connected with medicine and invoked especially against the plague were St. Roche and St. Sebastian, the latter being specially venerated in Umbria and Tuscany, the former in Venice. All round the gallery are hung a series of water-colour copies of illustrations from manuscripts dating from the fifth to the seventeenth century, and in the gallery itself are cases containing charms and amulets, many of them collected in the East-End of London or in country places in our own day. Belief in charms is by no means extinct even among educated persons in the present day. Thus, as Dr. Norman Moore mentioned in his address at the opening of the museum, he once met a lady who carried a potato in her pocket as a cure for rheumatism, and we ourselves have had a similar experience, only in that instance the complaint was neuritis.

In the central hall also are cases showing surgical and obstetrical instruments, Oriental, African, and Græco-Roman; and the probable source of inspiration of the speculum now known as Ferguson's is shown in a case which presents one of these instruments in juxtaposition with a speculum constructed, according to a description in the Talmud, from bamboo, and another formed from the stem and lower part of a gourd. The origin of the term speculum, which really means a mirror, is suggested in a drawing from a Flemish print of the sixteenth century, in which the method of examination of the internal passages is shown. A medical cleric is seated with his back to a woman in whom a three-bladed dilator (of which several specimens are shown) has been introduced into the anus. He holds a mirror (speculum) high up in front of him to catch over his shoulder the reflection of the rectum thus opened up. It is possible that reasons of propriety suggested this use of the mirror in place of direct inspection, and that when the mirror was discarded the name speculum was transferred to the dilator itself. This method of inspection by mirror and dilator is mentioned in a MS. by Bernard de Gordon (1301) and by Avicenna.

The illustrations from manuscripts are a most valuable and instructive series, and we should much like to see them reproduced on a smaller scale and published as a collection in book form, for they represent a scattered treasury of information that is mostly otherwise inaccessible. There are delightful pictures of the collection of mandrakes, of surgical operations, of scenes in hospital, of botanical drawings, from Dioscorides and ancient herbals, of St. Apollonia being tortured by having her teeth pulled out, of birth scenes of the Cæsarean operation, of physicians and nurses, of post-mortem examinations, and many others. One picture of great interest shows the Emperor Valerius, as he is called in the catalogue, but who is better known as Maximin Daza, being eaten by worms. This picture is numbered 45, and we fancy that No. 291, which is described in the catalogue as "King Suffering from a Parasitic Disease" is really another picture of Maximin, though it might be the Herod who suffered the same or a similar fate. Another Emperor, Galerius, traditionally died in the same manner. Those anxious to know more of this subject will find it treated at length in Dr. Richard Mead's "Medica Sacra" under the title of The Disease of King Herod.

Another section of the museum is devoted to pictures and engravings of medical scenes and to portraits and busts of medical men, prominent among which is a magnificent series of portraits of Harvey, in addition to a copy of his bust as it stands upon his tomb in Hempstead Church, Essex. These copies were made to the order of the late Sir George Paget, and the one in the museum is lent by MI. C. E. Paget. In the alcove is another equally interesting collection of portraits and relics of Jenner.

In the next room is a collection of MSS. and early printed books relating to medicine and surgery. A number of these were printed in English about the time of Queen Elizabeth, and deal mainly with surgery, for physicians at that period almost invariably wrote in Latin, and had, as a rule, a far better general education than surgeons. Some surgeons, however, knew Latin, for the author of a book called the "Key to Unknown Knowledge, or a Shop of Fine Windows," printed in 1599, deals in his first chapter with the judgment of urines, and says in a preliminary note that he has gathered together rules for the judgment of urine from divers authors for the benefit of his fellow chirurgians "which have not the Latine tongue."

Among the ancient MSS. of special interest are: Livre de Medécine d'Histoire Naturelle, by Huges de Salve, in French, dated 1390; MS. on Astrology, in Latin, Canones Super Tabulas, author unknown, dated 1296; MS. Inventory of the Hospital of St. John of Florence, dated 1397 to 1427; MS. Antidotarium, and other treatises, by Nicolaus Praepositus, in Latin, thirteenth and fourteenth centuries; MS. De Arte Medicine, with Ysagoge Johannicii, in Latin, fourteenth century; MS. Chirurgia, by Guglielmo di Saliceto, in Italian, fourteenth century; MS. A Treatis of Urines and Medicynes, in English, dated 1320. Among the more important Incunabula are: Practica de Medicinis, by Johannes Mesue, first edition, 1471; De Fructibus Vescendis, by Baptista Massa de Agenta, ca. 1471; Tractatus de Arte Cognoscendi Venena, by Arnoldus de Villanova, ca. 1473; De Medicina, by Cornelius Celsus, first edition, 1478; Tractatus de Regimine Sanitatis, Dominicus de Lapide, 1477; Liber Canonis, Gerard of Cremona, 1479; Herbarius zu Teutsch, Augsburg, 1496, the first German Herbal; De Morbo quem Gallicus vocatur, Coradinus Gilmus, 1497 (probably the earliest printed book on syphilis).

Here, also, in a glass show-case are an interesting collection of curious anatomical manikins, 15 in number, carved out of ivory, and showing the internal organs, the fœtus in utero, &c., in removable parts, which were probably used for instruction in midwifery in the fifteenth and sixteenth centuries; while in the basement below is a leather female manikin with dilated vulva and movable model of the fœtus and placenta, used in the seventeenth century for demonstrating the process of parturition to students in the old Hospital Pistoia.

In a gallery are a number of diplomas. Many of these from Italian Universities are beautifully illuminated. Harvey, it will be remembered, graduated at Padua, and a facsimile of his diploma was published in 1908 by the Royal College of Physicians. A copy of this facsimile is exhibited together with the portraits of Harvey. It was fully described in our columns at the time of publication. Among the diplomas may be specially referred to those granted to Joseph Serra in 1734 by the Medical College of Bologna, to Bernado José de Cavalho in 1777 by Mary, Queen of Portugal, to William Forester in 1608 by the University of Caen, and to Francis Henry in 1655 by the University of Montpelier. In the same section are a fifteenth century Italian manuscript document referring to a miraculous cure of pestilence which occurred in Venice in 1464, and a free pass in time of pestilence issued in 1713 at Riana, Tuscany, the only one known to be in existence. Another very interesting exhibit in this section is a facsimile Greek Drug Order of the first century, warning the vendor against selling stale or adulterated drugs. A demand from the rector and council of the University of Pavia to the Inquisitor of Witches, asking him to deliver for anatomical purposes the body of a woman who had been sentenced to be burnt alive indicates the pressure in the early sixteenth century in the problem of the supply of anatomical subjects.

The basement of the museum is mainly devoted to pharmacy. There is a reconstruction of John Bell's shop as many of us can remember it in Oxford-street. Bell was the founder of the Pharmaceutical Society, and the shop was

built in 1798. Another reconstruction shows a seventeenth century apothecary's shop which used to stand in the Old Bailey, and yet another, an alchemist's laboratory, *circa* sixteenth century, with original apparatus; also reconstructions of a barber-surgeon's shop (Fig. 1) and an accouchement room (Fig. 2), both of the sixteenth century, and of a Roman surgery in Pompeii. In this room also is a very fine collection of Italian and Flemish drug jars. Further along is a section devoted to nursing, with a number of portraits of Florence Nightingale.

We have reserved to the last some exhibits illustrating the more recent history of medicine. In the entrance hall is a collection illustrative of the progress of research in a matter that of late years has come greatly to the front—viz., pellagra. Dr. L. Sambon's theory is that the disease is due to the bite of the female simulium fly, of which insect specimens, both male and female, are shown under the microscope. Charts of regions where pellagra is endemic are shown, indicating that the distribution of the disease in all countries follows the course of swift-running streams in the high lands midway between the plains and the mountains. The distribution is, in fact, inverse to that of malaria, for the anopheles lays its eggs in the stagnant waters of the lowlands, while the simulium finds its most favourable environment for development in the rippling streams and freshets. The simulia have only a brief life in the torrential streams of the mountains, and are scarcely found in the sluggish streams of the low-lying lands. There is also a seasonal prevalence of the fly in the spring when freshets are abundant. This proof of the correspondence of the distribution of the disease with that of the simulium is displayed in charts of the Provinces of Urbino, Pavia, Brescia, Udine, and Venezia in Italy, as well as in charts of Northern Italy, Roumania, the Tyrol, and particularly the province of Bucharest. The outstanding fact in the province of Bucharest particularly is that the peasants live under similar conditions, including the use of the same maize diet in both districts; yet those in the plains are free from pellagra, while the disease abounds in the hilly districts where simulia are abundant. There are also coloured plates of the recent cases in England and pictures showing that the places where these cases have been found are similar in character to those in other lands where the disease is endemic. Further, there is a tube containing simulium larvæ found at Catford.

We have by no means exhausted the contents of this museum, the organisation of which must have involved an immense amount of enthusiasm and hard work, but Mr. Wellcome deserves the thanks of the whole medical profession, not only for having collected all the objects which he has (and in this matter we must associate Mr. C. J. S. Thompson who has arranged them), but also for his intention of making the present museum the foundation of a permanent historical medical museum in London. The museum will close this year on Oct. 31st, but we are informed that it will be reopened as a permanent museum some time in 1914. During October the museum will be open from 10 A.M. to 6 P.M. daily, and from 10 A.M. to 1 P.M. on Saturdays.

THE INTERNATIONAL CONGRESS OF PHARMACY.

SINCE the Tenth International Congress of Pharmacy was held in Brussels in 1910,[1] a permanent International Pharmaceutical Federation has been established, with the result that the eleventh congress, which was organised by the Federation and held at the Hague during the third week in September this year, was the most successful of the whole series. It was truly representative in character, since it was attended by delegates of 18 different nationalities. The British representatives were Mr. Edmund White, President of the Pharmaceutical Society, who was the delegate of the British Government; Mr. W. J. U. Woolcock, secretary of the Pharmaceutical Society; Professor H. G. Greenish, joint editor of the British Pharmacopœia; Mr. E. S. Peck, and Mr. H. Finnemore. The delegate from the United States was Professor J. P. Remington, editor of the United States Pharmacopœia, while many other countries sent their most distinguished pharmaceutical professors. The President was Professor L. van Itallie of the University of Leyden.

[1] THE LANCET, Sept. 17th, 1910, p. 909.

Proposed International Pharmacopœial Bureau.—Unification of Nomenclature.

As is usually the case with international meetings the papers were very numerous, and time did not permit of the adequate discussion of the majority of them. The most important subject from the international point of view was the proposal to establish an international pharmacopœial bureau for the purpose of examining, abstracting, and sifting all literature relating to pharmacopœial work. As so many of the delegates are members of the revision committees of their national pharmacopœias the matter was discussed with much earnestness, and it was decided to appoint a commission of seven members to consider whether the formation of such a bureau is desirable, and to report to the federation; the British representative on the commission is Professor Greenish and the American Professor Remington. Should the bureau be formed not only would the work of revision committees be simplified, but each national pharmacopœia committee would profit by the experiences of all the others. It is, therefore, to be hoped that the commission will see its way to reporting favourably on the proposal. Another subject of discussion well suited to the purpose of an international meeting was that of the unification of pharmaceutical nomenclature. The general opinion was that a universal nomenclature was desirable, and it was left to the federation to consider the matter in detail. M. C. Rousseau, who brought the proposal forward, suggested that in pharmacopœias an international name should be printed in brackets after the national name, and that where Latin words were not employed the international name should be in Esperanto.

Trade Marks, Synthesis of Glucosides, &c.

The application of trade marks to chemical products used in medicine was the subject of another interesting discussion. The president of the Pharmaceutical Society, who made a valuable contribution to the discussion, suggested among other things that brand names should not be applied to substances which were not originated by the owners of the trade marks. The Congress passed a resolution embodying the recommendation that every medicinal substance bearing a trade mark name should also bear an ordinary name from the use of which the owner of the trade mark would suffer no loss of rights. A lecture on the Synthesis of Glucosides by means of Ferments by Professor Bourquelot of Paris was probably the most important feature of the Congress. Professor Bourquelot is the most eminent worker in this special field of research, and he and his collaborators have succeeded in synthesising many glucosides by means of enzymes. He gave a most interesting account of his work, and made, for the first time, the extremely important announcement that he had recently discovered that the action of enzymes is synthetic as well as analytical. Up to a point the action of a ferment is to break up a glucoside, but at this point the synthetic action begins. The decomposing process ceases when a certain proportion of the product of decomposition is present. Hitherto it has been supposed that the action of ferments is a decomposing one only, and this discovery opens up a new field of research. Professor Tschirch, of Berne, another distinguished research chemist, gave an address on the Importance of Enzymes in Pharmacognosy; he drew attention to the fact that parts of living plants change considerably after they have been removed from the plant, and showed that these changes are in some cases due to enzyme action and are preventable by the destruction of the enzyme. Whether or not the changes are beneficial depends upon the purpose for which the drug is intended, and in view of this consideration Professor Tschirch discussed the question of the advisability of sterilising fresh vegetable substances used in medicine. The value of the cinematograph in pharmaceutical lectures was demonstrated by Professor Wijsman, of Utrecht, whose paper on the Cultivation of Drugs in the Dutch Colonies was illustrated by moving pictures showing how cinchona bark is cultivated in Java. The next congress is to be held in Berne in 1915.

A GERMAN GIFT FOR THE PURCHASE OF RADIUM.—A Würtemberg manufacturer has given to the Ministry of Education the sum of 50,000 marks (£2500) for the purchase of radium and mesothorium.

LOCAL GOVERNMENT BOARD FOR IRELAND: ANNUAL REPORT FOR 1912–13.

THE forty-first annual report of the Irish Local Government Board has just reached us. It relates to the Board's proceedings during the year ending Lady Day, 1913, and contains evidence of satisfactory progress in sanitary administration in that division of the United Kingdom. From a medical standpoint it is important to note that sanitary operations in Ireland are regulated by a staff of medical inspectors, to each of whom is committed the charge of a definite area of the country. The reports of these officers form the source from which the present summary is derived. Particulars of the mortality from various causes in Ireland are cited from the report of the Registrar-General, to which reference has already been made in THE LANCET.[1] At the period covered by this report the provisions of the Infectious Diseases (Notification) Act had been adopted in 145 rural and 86 urban districts. In the first-named areas 3082 and in the last-named 6196 cases of infectious diseases were notified in the course of the year.

Typhus Fever.

Happily, this pestilence occurs rarely in England, and few of the rising generation of medical practitioners have ever seen a case. But in several parts of Ireland it seems to be practically endemic. In the year under notice 126 cases of typhus were notified in Ireland, but this number by no means represents the total incidence of the disease—partly because notification is not yet universally compulsory, but more especially because of the notorious fact that the initial cases of outbreaks frequently escape recognition. None of the outbreaks assumed alarming proportions last year, but a considerable number of attacks were reported from Galway and Dublin. Dr. Brian O'Brien gives an account of an epidemic visitation of typhus fever of an atypical character in the Stranorlar rural district, the origin of which was traced with much probability to infection conveyed in second-hand clothes. The Board refer with regret to the death of Mr. E. L. Aherin from typhus contracted in the course of his official duties in the Newcastle Dispensary district. In the county borough of Cork, where the disease has been of frequent occurrence in past years, only one case of typhus occurred in the period under review. Belfast also is stated to have been free from this fever.

Enteric Fever.

Throughout Ireland a gratifying reduction is reported in the incidence of enteric fever last year, when the number of notified cases was the lowest on record. Dr. T. J. Browne, the district medical inspector, reports that in Dublin the notifications were less than half as numerous as in the preceding year. Sir J. Acheson McCullagh, medical inspector for the Oughterard rural district, reports that enteric fever is more or less endemic in that locality. The water-supply is bad, mainly from wells, or rather holes in the field, and is liable to pollution in every form. The housing conditions also are insanitary. The fever in these cases was not of a pronounced type as regards the characteristics either of typhus or of enteric fever. "It was more of the 'mongrel type,' which is found so often on the western seaboard."

Tuberculosis.

Commenting on the circumstance that hitherto the notification of tuberculosis, under the Act of 1908, has been adopted in 41 districts only, the Local Government Board express the hope that before long steps will be taken to make notification compulsory, at any rate in all large urban districts. This is especially necessary as regards the boroughs of Cork and Waterford, where the incidence of phthisis is particularly heavy. In Dublin and in Belfast the notifications fall short of the recorded deaths from pulmonary tuberculosis; they cannot, therefore, be regarded as even an approximate index of the prevalence of the disease. In the interest alike of the patients themselves and of the community, the Board insist on the importance of securing notification of attacks before the disease has reached an advanced stage, and they impress upon sanitary authorities the necessity of acting on this principle.

The Board show considerable energy in supporting measures for the detection, prevention, and treatment of tuberculosis. Particulars are given of the progress already achieved, and of the advice and assistance rendered by the Board's expert advisers to local authorities who are responsible under the Tuberculosis Prevention Act.

The reports of the Board's medical inspectors contain accounts of their action in regard to the sanitation of their districts, together with statistics of diseases prevalent, and of the steps locally taken for its prevention. To these reports the attention of those interested in the health and well-being of Ireland may usefully be directed.

[1] THE LANCET, Sept. 27th, 1913, p. 947.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

Borough of Leicester.—The information given by Dr. C. K. Millard in his last report shows that the year 1912 was notable in various ways in the sanitary history of Leicester. The great Derwent Valley water undertaking was completed, and this source of supply was made available in September. The water is soft and organically pure, but has a brownish colour, due to its peaty origin, which at first was very pronounced. At present the new supply is being used in conjunction with the old service obtained from Charnwood Forest. During the year "sanatorium benefit" came into operation, and owing to the borough being already comparatively well equipped for the purpose, not only in respect of hospital accommodation but also by means of the tuberculosis dispensary which had been established in 1911, little difficulty was experienced in administering it. In order that the medical officer of health might act as administrative tuberculosis officer and medical adviser to the Insurance Committee a new arrangement was made by which the posts of medical officer and public analyst have been dissociated. Another noteworthy feature of the year was the virtual non-appearance of an autumnal diarrhœa epidemic. In past years these epidemics were a conspicuous feature of Leicester, which had the reputation of being a "diarrhœa town"; since the period 1898 to 1902, in which over 5000 pail closets were converted into water-closets, and other efforts made on a large scale to secure cleanly surroundings of dwellings, these annual outbreaks have been of much less intensity. The five years 1894–98 had an average diarrhœa mortality rate per 1000 births of 50·6; in the next five years 1899–1903 the rate was 39·7, for 1904–08 it was 34·5, and in the four years 1909–12 it has been as low as 18·7. In 1912 itself, a year meteorologically unfavourable to diarrhœa prevalence, the rate was only 6·5. The rate of infantile mortality from all causes has shown a corresponding decline, and it is noteworthy that this has taken place in a town which has not adopted the system of compulsory notification of births. It is possible that the objection to the latter measure may in part result from the high proportion of illegitimate births in Leicester; for 1912 such births were 5·1 per cent. of the whole. The municipal infants' milk depôt, unlike those in some other cities, has prospered. It is increasingly used, and is now said to be paying its way. Dried milk is exclusively used, the prices charged during the summer per pound being 1*s.* for full cream milk, 10*d.* for "three-quarters cream," and 9*d.* for half cream. Reduced charges have been made in special cases, while the payments for the milk in some instances have been made by the Charity Organisation Society and by the Leicester guardians. The number of infants taken on the books, for longer or shorter periods, was 898 during the year. Infant consultations are held in connexion with the work of the depôt. About half the births in Leicester are computed to be attended by certified midwives, of whom there are 29. Dr. Millard does not consider the number to be inadequate. Some of the Leicester midwives are said to attend 150 or even more confinements a year. A small outbreak of enteric fever during August was traced to the consumption of a particular batch of ice cream, made on premises on which an ambulant case of the disease was at work. Appended to the report are a number of useful statistical tables relating to infectious diseases, hospital treatment, and other matters. We are

glad to note that Leicester is taking part in the investigations of atmospheric pollution which are being made by the committee, of which Dr. W. N. Shaw, of the Meteorological Office, is chairman.[1]

County of Ross and Cromarty.—Dr. William Bruce gives an interesting report on the conditions which obtain in the scattered communities in this large area of the Highlands and in the Island of Lewis. He lays particular stress on the value of the school as a means of hygienic teaching, which he considers is not sufficiently utilised. He urges also, in the interests of growing children, that they should be allowed a respite from mental work as far as possible about the age of 12, and commends the old system of the children going to school in winter and being set free during the summer months, an arrangement to which, it is understood, the Scottish Education Department is not unfavourable. To make this plan successful, however, it would, of course, be necessary to extend the present age of compulsory attendance. The county possesses a sanatorium for early cases of tuberculosis, established by private munificence. The limited experience of notification of pulmonary tuberculosis suggests that about 200 cases will in future have to be dealt with in the whole county. Of these perhaps 100 will be cases on the mainland, and Dr. Bruce computes that here hospital accommodation would be required for at least 20. The bulk of the treatment of tuberculosis must be carried out at the homes, and for this purpose the prospect of the establishment of a satisfactory system of parish nursing, held out by the report of the recent Committee on the Medical Services of the Highlands and Islands, is greatly welcomed. The essence of sanitary improvement in many parts of this district lies in the solution of the housing problem, and Dr. Bruce urges that although the outlay of better houses may for the time being be unremunerative, it cannot fail to give ultimately an invaluable return. The Island of Lewis furnishes nearly 26,000 of the total inhabitants of the country who are estimated at 61,751, and special prominence is given to the report made on this area by Dr. D. Murray of Stornoway. In recent years a great deal of public attention has been given to the insanitary conditions of Lewis, but it is satisfactory to find evidence that considerable activity in sanitary work is now taking place. There is a considerable demand for new houses, while the objections to the "black houses" of the old type have been so much insisted upon that many of the islanders consider it useless to attempt any improvement of their older dwellings, and prefer to wait for new houses. The "black houses" in question are those in which the dwelling and the byre are under a single roof, with a vitiated atmosphere, and interiors that are damp, smoky, and sunless. Dr. Murray urges that those who are able to make a complete separation between the dwelling and the byre should at once be forced to do so. There is a hospital at Stornoway, but it is reported to be too far removed from many parts of the districts to be of much practical value. The record of the island for infectious diseases during the year appears to have been favourable; only three cases of enteric fever occurred, and an outbreak which followed importation of measles from the mainland was promptly checked. On previous occasions a very serious mortality from measles has resulted from its introduction in this way. The death-rate from all causes during the year was 13·56 per 1000 of the population, and the infantile mortality was distinctly low, not exceeding 49 per 1000 births.

The Island of Guernsey.—The population of this island is now estimated at 41,854, and in 1912 the natural increase of births over deaths was 431. Emigration is, however, actively going on, and Dr. Draper Bishop lays stress upon the fact that the emigrants are people of a desirable class and that it is a matter for regret that the prospects of life in newer countries cause them to leave Guernsey. On the other hand, immigration of aliens is also active, and it appears that they are not considered to be equally desirable persons. Dr. Bishop states that the immigrants are answerable for an altogether undue amount of crime and drunkenness, and that as a class they live in such conditions of overcrowding and insanitation as to constitute a great danger to the bodily health of the community in general. The immigrant population of which he principally complains appears to be of French rather than of British origin. The death-rate for 1912 was a low one 13·1 per 1000, as compared with 14·9, the average for the previous ten years. This circumstance in Guernsey, as on the mainland, is largely to be attributed to the cool and wet summer which favoured a low rate of infantile mortality. There was not a single death in 1912 from epidemic enteritis, which had caused 60 deaths in the previous year, and there were only two deaths from measles and none from whooping-cough, as compared with 18 and 11 respectively in the previous year. On the other hand, diphtheria seems to be considerably prevalent, 139 cases of this disease being included among the total of 270 cases of notifiable infectious diseases admitted to the King Edward Sanatorium during the year. As this sanatorium is only designed for the accommodation of 22 patients, its capacity has often been taxed to the limit, and at times it has been greatly overcrowded. In the parts of the island remote from the town Dr. Bishop considers that the belief in "witchcraft" and "overlooking" which still obtains has much to do with the spread of diphtheria. He also points out that the prevalence of infectious diseases generally is often maintained through the reluctance of the class termed "stranger poor" to make application to the proper authorities for medical relief. The system by which the poorer classes of the island can receive medical treatment, indeed, appears to be very deficient on account of the requirement that the patient, no matter where he lives, can only be attended by the doctor of his original parish. Although notification of pulmonary tuberculosis was made compulsory in the early part of 1912, and a certain number of cases were notified, no practical steps appear to have been taken to deal with this disease beyond the routine disinfection of rooms which have been occupied by consumptive persons. Dr. Bishop rightly points to many of the natural advantages of the island from the public health point of view, such as its abundant sunshine and its tubercle-free milk, but he also indicates that there are serious deficiencies in its sanitary organisation which cannot fail to be detrimental both to residents and visitors. While he considers that it would be unadvisable to cumber the local statutes by the inclusion of the many Acts and Regulations at present in force in England, he points out that the powers of the Board of Health need to be expanded so as to form one working sanitary authority for the whole island. Such an authority should devote its first attention to the improvement of the water-supply, the extension of the system of drainage in certain congested areas, the efficient collection and disposal of household refuse, the provision of suitable sanitary dwellings for the working classes, and the medical inspection of the school children.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns, with populations exceeding 50,000 persons at the last Census and whose aggregate population at the middle of this year is estimated at 17,852,766 persons, 8475 births and 4936 deaths were registered during the week ended Saturday, Sept. 27th. The annual rate of mortality in these towns, which had been 13·8, 14·5, and 14·3 per 1000 in the three preceding weeks, slightly rose to 14·4 per 1000 in the week under notice. During the thirteen weeks of the quarter just ended the annual death-rate in these towns averaged 12·7, against 11·8 per 1000 in London during the same period. Among the several towns the death-rate last week ranged from 5·4 in Ilford, 6·5 in Hornsey, 6·7 in Gillingham, 7·3 in Willesden, and 7·9 in Carlisle, to 21·8 in Rochdale, 22·0 in Bury, 22·6 in South Shields, 23·6 in Stockport, and 24·0 in Sunderland.

The 4936 deaths from all causes were 38 in excess of the number in the previous week, and included 1081 which were referred to the principal epidemic diseases, against 1242 and 1118 in the two preceding weeks. Of these 1081 deaths, 927 resulted from infantile diarrhœal diseases, 49 from whooping-cough, 38 from diphtheria, 31 from measles, 19 from scarlet fever, and 17 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 3·2, against 3·6 and 3·3 per 1000 in the two preceding weeks. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had been 960, 1104, and 983 in the three preceding weeks, further declined to 927 last week; of this number 191 were recorded in London, 65 in Birmingham,

64 in Liverpool, 36 in Manchester, 32 in Hull, 24 in Leeds, in Sheffield, and in Sunderland, 22 in West Ham, and 21 in Bradford. The deaths referred to whooping-cough, which had been 31, 38, and 44 in the three preceding weeks, further rose to 49 last week, and included 11 in London, 5 in Sheffield, 4 in Manchester, and 3 in Norwich. The fatal cases of measles, which had steadily declined from 77 to 20 in the nine preceding weeks, rose to 31 last week; 4 deaths occurred in London, in Oldham, and in Sheffield, 3 in Stoke-on-Trent, 3 in Dudley, 2 in Manchester, and 2 in Sunderland. The deaths attributed to diphtheria, which had been 45, 36, and 40 in the three preceding weeks, declined to 38 last week, and included 7 in London, 3 in Leeds, and 2 each in Bristol, in Birmingham, and in Birkenhead. The deaths referred to scarlet fever, which had been 17, 28, and 18 in the three preceding weeks, were 19 last week, of which number 5 were registered in Birmingham, 3 in Manchester, 3 in Sheffield, and 2 in London. The fatal cases of enteric fever, which had been 13, 10, and 13 in the three preceding weeks, rose to 17 last week, and included 4 in London, 2 in Manchester, and 2 in Hull.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had been 2112, 2211, and 2355 at the end of the three preceding weeks, had further risen to 2570 on Saturday last; 508 new cases were admitted during the week, against 298, 346, and 473 in the three preceding weeks. These hospitals also contained on Saturday last 913 cases of diphtheria, 198 of whooping-cough, 79 of measles, and 57 of enteric fever, but not one of small-pox. The 1167 deaths from all causes in London were 20 fewer than the number in the previous week, and were equal to an annual death-rate of 13·5 per 1000. The deaths referred to diseases of the respiratory system, which had been 132, 132, and 125 in the three preceding weeks, rose to 134 last week, but were 35 below the number in the corresponding week of last year.

Of the 4936 deaths from all causes in the 96 towns, 157 resulted from various forms of violence and 331 were the subject of coroners' inquests. The causes of 30, or 0·6 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Sheffield, Leeds, Bristol, West Ham, Bradford, Hull, Newcastle-on-Tyne, and in 72 other smaller towns. Of the 30 uncertified causes of death, 5 were registered in Birmingham, 4 in Liverpool, 3 in Stoke-on-Trent, 3 in Sunderland, and 2 each in Bury, in Burnley, and in Gateshead.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns, with an aggregate population estimated at 2,259,600 persons at the middle of this year, 1075 births and 653 deaths were registered during the week ended Saturday, Sept. 27th. The annual rate of mortality in these towns, which had been 16·7, 16·4, and 14·4 per 1000 in the three preceding weeks, rose to 15·1 per 1000 in the week under notice. During the thirteen weeks of the quarter just ended the mean annual death-rate in these towns averaged 14·3, against a corresponding rate of 12·7 per 1000 in the 96 large English towns. Among the several towns the death-rate last week ranged from 7·2 in Coatbridge, 8·5 in Clydebank, and 9·7 in Paisley, to 19·5 in Dundee, 19·9 in Ayr, and 20·3 in Hamilton.

The 653 deaths from all causes were 28 in excess of the number in the previous week, and included 90 which were referred to the principal epidemic diseases, against 126 and 94 in the two preceding weeks. Of these 90 deaths, 55 resulted from infantile diarrhœal diseases, 10 from measles, 10 from diphtheria, 6 from whooping-cough, 5 from scarlet fever, and 4 from enteric fever, but not one from small-pox. These 90 deaths from the principal epidemic diseases were equal to an annual death-rate of 2·1, against 3·2 per 1000 in the 96 large English towns. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had been 89, 96, and 62 in the three preceding weeks, further declined to 55 last week, and included 25 in Glasgow, 9 in Dundee, 5 in Paisley, and 3 in Aberdeen. The deaths referred to measles, which had been 14, 12, and 9 in the three preceding weeks, were 10 last week, and comprised 7 in Glasgow, 2 in Hamilton, and 1 in Leith. The fatal cases of diphtheria, which had been 6, 7, and 8 in the three preceding weeks, further rose to 10 last week, of which 4 occurred in Glasgow and 2 in Aberdeen. The deaths attributed to whooping-cough, which had been 6, 5, and 9 in the three preceding weeks, fell to 6 last week, and included 4 in Glasgow. The 5 deaths referred to scarlet fever, of which 3 were recorded in Glasgow, were equal to the average in the five preceding weeks. The 4 fatal cases of enteric fever, comprising 2 in Perth, 1 in Glasgow, and 1 in Falkirk, were slightly above the average in the earlier weeks of the quarter.

The deaths referred to diseases of the respiratory system, which had been 86, 65, and 63 in the three preceding weeks, slightly rose to 66 in the week under notice; 26 deaths resulted from various forms of violence, against 25 and 17 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,199,180 persons at the middle of this year, 665 births and 483 deaths were registered during the week ended Saturday, Sept. 27th. The annual rate of mortality in these towns, which had been 19·9, 21·1, and 19·8 per 1000 in the three preceding weeks, rose to 21·0 per 1000 in the week under notice. During the 13 weeks of the quarter just ended the mean annual death-rate in these Irish towns averaged 18·2 per 1000; in the 96 large English towns the corresponding rate did not exceed 12·7, while in the 16 Scotch towns it was equal to 14·3 per 1000. The annual death-rate last week was equal to 21·2 in Dublin (against 13·5 in London and 16·2 in Glasgow), 19·5 in Belfast, 24·5 in Cork, 22·9 in Londonderry, 17·6 in Limerick, and 26·6 in Waterford, while in the 21 remaining smaller towns the mean death-rate was equal to 21·6 per 1000.

The 483 deaths from all causes were 28 in excess of the number in the previous week, and included 103 which were referred to the principal epidemic diseases, against 132 and 120 in the two preceding weeks. Of these 103 deaths, 84 resulted from infantile diarrhœal diseases, 9 from whooping-cough, 5 from measles, 3 from scarlet fever, 1 from enteric fever, and 1 from diphtheria, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 4·5 per 1000; in the 96 large English towns the corresponding rate was 3·2, while in the 16 Scotch towns it did not exceed 2·1 per 1000. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had been 92, 111, and 98 in the three preceding weeks, further declined to 84 last week, and included 33 in Dublin, 22 in Belfast, 8 in Cork, 5 in Londonderry, 3 in Waterford, and 3 in Dundalk. The deaths referred to whooping-cough, which had been 6, 6, and 2 in the three preceding weeks, rose to 9 last week, all of which occurred in Galway. The fatal cases of measles, which had been 10, 2, and 7 in the three preceding weeks, were 5 last week, and comprised 4 in Galway and 1 in Waterford. The 3 deaths attributed to scarlet fever and the fatal cases of enteric fever and diphtheria were all recorded in Belfast.

The deaths referred to diseases of the respiratory system, which had been 42, 41, and 56 in the three preceding weeks, rose to 60 in the week under notice. Of the 483 deaths from all causes, 128, or 27 per cent., occurred in public institutions, and 9 resulted from various forms of violence. The causes of 6, or 1·2 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 96 large English towns the proportion of uncertified causes of death last week did not exceed 0·6 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeons: E. D. J. O'Malley to the *Temeraire* on recommissioning; W. K. Hopkins to the *Vivid*, additional, for the *Fearless*, and on commissioning; J. H. Stenhouse to Bermuda Hospital and Dockyard; W. A. Whitelegge to the *Queen*; F. Fedarb to the *Hibernia*; F. Bradshaw to the *Princess Royal*; E. H. Hodnet de Courtmacsherry to Chatham Dockyard; and E. G. E. O'Leary to the *Indefatigable*,

Staff-Surgeons: M. Cameron to the *President*, additional, for Queensferry Sick Quarters, temporarily; and H. J. Chater and J. MacDonald to the *Calypse* and the *Adventure* respectively. Surgeons: C. H. Symons to Malta Hospital and J. G. Boal to the *Temeraire*, on recommissioning.

ROYAL ARMY MEDICAL CORPS.

Captain Douglas P. Watson is seconded for service under the Colonial Office (dated Sept. 10th, 1913).

Lieutenant-Colonel H. M. Adamson has been placed under orders for a tour of service in India, embarking from Southampton on Oct. 22nd, and on arrival will be appointed to the Southern Army. Lieutenant-Colonel T. B. Winter has taken up duty as officiating Assistant-Director of Medical Services to the Colchester District during the absence on special duty of Colonel F. J. Jencken. Approval has been given by the Director-General for an exchange on the roster for service abroad between Brevet-Colonel and Lieutenant-Colonel C. H. Melville, in charge of the Military Hospital at Lucknow Cantonment, and Lieutenant-Colonel J. M. F. Shine, in charge of the Military Hospital at Belfast. Lieutenant-Colonel C. C. Reilly has been transferred from the Military Hospital at Colaba, Bombay, to the Presidency Brigade and appointed to hold charge of the Military Hospital at Darjeeling Cantonment. Lieutenant-Colonel H. D. Rowan has been appointed to hold charge of King George V. Military Hospital at Dublin in succession to Lieutenant-Colonel W. C. Beevor, C.M.G. Lieutenant-Colonel H. J. Pocock has been transferred from the Military Hospital at Campbellpore to Murree Cantonment. Lieutenant-Colonel R. J. W. Mawhinny has taken up duty as Senior Medical Officer at Jullunder Cantonment. Lieutenant-Colonel W. T. Mould has been appointed to hold charge of the Military Hospital at Fyzabad Cantonment.

Major P. H. Collingwood has been transferred from medical charge at Honiton Camp to the Military Hospital at Devonport. Major W. S. Crosthwait has taken over charge of the Military Hospital at Upper Topa, Murree Hills District, on transfer from Ambala Cantonment. Major F. Harvey has been placed under orders to embark for a tour of service in India on Oct. 9th, and on arrival will be appointed to the Southern Army. Major B. F. Wingate has taken over charge of the Military Hospital at Bellary Cantonment, Madras Presidency. Major J. H. Brunskill has been transferred from the Military Hospital at the Curragh Camp to the Dublin District, and appointed Specialist Sanitary Officer in succession to Major D. J. Collins, who has embarked for a tour of service in India. Major H. K. Palmer has been appointed to officiate in medical charge of 18th Regiment of Native Infantry, Indian Army, at Aden. Major J. G. Gill has joined for duty at Maymyo. Major E. F. Q. L'Estrange has taken over charge of the Military Hospital at Cannanore Cantonment. Major F. W. Begbie has been appointed Specialist in Operative Surgery to the Fifth (Mhow) Division of the Southern Army in India. Major H. O. B. Browne-Mason has been appointed to officiate as Deputy Assistant Director of Medical Services to the Sixth (Poona) Division. Major A. W. N. Bowen has taken over charge of the Military Hospital at Kirkee Cantonment.

Captain J. W. S. Seccombe has been transferred from the Royal Army Medical Corps Camp of Instruction at Tidworth Park, Salisbury Plain, to the Military Hospital at Topsham. Captain J. B. Meldon has taken up duty at Eastbourne on transfer from the Military Hospital at Shorncliffe. Captain G. W. G. Hughes has been appointed to the Military Hospital at Devonport on conclusion of the course of instruction for promotion to the rank of major at the Royal Army Medical College, Grosvenor-road, S.W. Captain P. J. Hanafin has been transferred from King George V. Military Hospital, Dublin, and appointed to hold medical charge at Rogerstown Camp. Captain N. Low has been selected for appointment as Specialist in State Medicine at the recent promotion examination held at the Royal Army Medical College. Captain H. W. Russell has been placed under orders to embark at Southampton on Oct. 9th for a tour of service in India, and on arrival will be appointed to the Northern Army for duty. Captain C. P. O'Brien-Butler has been granted one month's extension of general leave of absence home from India. Captain J. C. Sproule has been transferred from the Military Hospital at Devonport to Crown Hill. Captain M. J. Cromie has joined at Chatham. Captain R. H. L. Cordner has been appointed Specialist in Physical Training. Captain J. E. M. Boyd has been allowed to extend his Indian tour of service for one year. Captain M. Keane has joined at Warwick. Captain J. H. Foster has been granted general leave of absence home from India until Feb. 3rd next, with permission to revert to the Home establishment at its expiration. Captain C. J. Coppinger has been selected for appointment as Specialist in Bacteriology. Captain J. G. Bell has been placed under orders to proceed to the Straits Settlements for a tour of service. Captain J. W. Lane has been granted six and a half months' general leave of absence home from the Indian establishment. Captain J. E. Hoar has been appointed Specialist in Dermatology and Venereal Diseases. Captain R. E. U. Newman has been transferred from the Military Hospital at Chatham and appointed to hold medical charge at Landguard Fort. Captain J. W. L. Scott has been appointed to the staff at the Royal Victoria Hospital, Netley, on transfer from Durrington Camp, Salisbury Plain. Captain V. H. Symons has joined for duty at Seaforth. Captain G. E. Ferguson has been selected for appointment as Specialist. Captain P. Power has embarked for a tour of service with the Southern Army in India. Captain C. T. Edmunds has been transferred from the Military Hospital at Bulford Camp, Salisbury Plain, to Sonning-on-Thames. Captain J. A. Renshaw has taken up duty at the Military Hospital, Secunderabad Cantonment, on transfer from the Bangalore Brigade of the Southern Army. Captain R. A. Bryden has been appointed to the Military Hospital at Preston.

Lieutenant C. J. H. Little has been appointed to the Northern Command for duty. Orders have been issued for Lieutenant H. R. L'Estrange, attached to the Military Hospital at Newbridge, to be held in readiness to embark for service in Mauritius on Nov. 1st next. Lieutenant J. B. A. Wigmore has been appointed to the Aldershot Command for duty. Lieutenant E. B. Allnutt has been placed under orders to embark from Southampton for a tour of duty in India on Oct. 9th, and on arrival will be appointed to the Southern Army. Lieutenant N. W. Stevens has been transferred from Shorncliffe to the Military Hospital at Dover. Lieutenant E. P. A. Smith has taken up duty in the Aldershot Command. Lieutenant R. B. Phillips has been transferred from the Military Hospital at Cork and appointed to hold medical charge at Ballcannon Camp. Lieutenant E. A. Strachan has joined at Barry. Lieutenant C. C. Jones has been appointed to the London District. Lieutenant H. Beddingfield has joined the Eastern Command for a tour of duty. Lieutenant W. J. Webster has been placed under orders to embark for a tour of service at Malta. Lieutenant G. H. Dive has joined at Pekin. Lieutenant A. A. M. Davies has been appointed to the Northern Command. Lieutenant T. J. Hallinan has been transferred from the Military Hospital at Lucknow Cantonment to the Presidency Brigade and appointed to the Military Hospital at Fort William, Calcutta. Lieutenant L. Dunbar has been appointed to the Southern Command.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel J. Davison, D.S.O., has arrived home on leave of absence from India. Lieutenant-Colonel W. R. Edwards, C.M.G., has been selected for appointment as Agency Surgeon of the First Class under the Foreign Department of the Government of India, consequent on the retirement from the service of Lieutenant-Colonel H. R. Woolbert. Lieutenant-Colonel C. H. James, C.I.E., has been confirmed in the appointment of Civil Surgeon at Simla (West).

Major R. F. Baird, civil surgeon to the Gonda District, has been transferred to Benares. Major J. Husband has been selected for appointment to hold civil medical charge at Dera Ismail Khan. Major H. M. Mackenzie has been granted leave of absence home from India, combined with furlough, for one year and seven months. The services of Major W. H. Kenrick have been placed at the disposal of the Sanitary Commissioner of the Central Provinces for employment on Malaria Survey duty. Major D. McCay, professor of physiology at the Government Medical College, Calcutta, has been appointed Second Physician to the College Hospital, Calcutta, during the absence on special duty of Lieutenant-Colonel B. H. Deare. Major G. Hutcheson, civil surgeon at Aligarh, has been granted leave of absence home from India for one year and eight months. Major F. W. Sumner, on completion of special duty at the Central

Research Institute, Kasauli Cantonment, has been appointed to hold civil medical charge at Farrukhabad.

Captain M. J. Quirke has been appointed permanently to the Civil Medical Department of the Government of Madras Presidency. Captain R. H. Bott has been appointed to officiate as Professor of Surgery at the Government Medical College, Lahore, during the absence on leave of Lieutenant-Colonel E. V. Hugo. Captain P. S. Milis has arrived home on leave of absence from India. The services of Captain C. H. Reinhold have been placed at the disposal of the Government of the United Provinces of Agra and Oudh for officiating civil medical employment. Captain M. R. C. MacWatters, officiating civil surgeon, on completion of special duty, has been appointed to officiate as Chemical Examiner, Government Analyst, and Bacteriologist to the United Provinces of Agra and Oudh and to the Central Provinces Administration, in succession to Captain V. B. Nesfield. Captain H. H. Thorburn, agency surgeon to the Foreign Department of the Government of India, has been granted privilege leave of absence for two and a half months. Captain J. F. Crawley has embarked on medical charge of troops on board the transport s.s. *Barjora* for the Persian Gulf. Captain H. P. Cook has been transferred from the Foreign Department of the Government of India for duty under the Education Department. Captain H. Broome has been granted an extension of his leave of absence home from India. The services of Captain L. Hirsch have been placed permanently at the disposal of the Government of Madras for civil medical employment.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Henry Colwell Rook, late Cadet Staff Sergeant, University of London Contingent, Officers Training Corps, to be Lieutenant (on probation) (dated Sept. 4th, 1913).

TERRITORIAL FORCE.

Royal Army Medical Corps.

2nd Highland Field Ambulance, Royal Army Medical Corps: Captain John Innes resigns his commission (dated Sept. 27th, 1913).

Attached to Units other than Medical Units.—Charles Ernest Anderson to be Lieutenant (dated July 2nd, 1913).

DEATHS IN THE SERVICES.

Surgeon-Major David Woods, late A.M.S., at Camberley, in his 84th year. He formerly served as a surgeon in the Royal Artillery.

THE MEDICAL DEPARTMENT OF THE RUSSIAN ARMY.

The medical service of the Russian Army has made a great advance. In 1912 hospital commandants were abolished and the senior medical officer was made responsible for the whole of the management of his hospital. There was a mutiny in the Imperial Medical Academy in March, says the *Journal of the Royal United Service Institution*, but the school has been reorganised, and the students are now under military discipline. Of students there are 850, of whom 523 receive their education free. In the field there are four hospital beds with each battalion, and the battalion provides the first dressing station in action, the collecting station is equipped by the brigade or divisional hospital, which hands the sick and wounded over to the ambulance companies for conveyance to the base. The new ambulance cart is two-wheeled with springs and a hood, holding two stretchers and seats besides. It weighs 560 lb. empty, half-a-ton when loaded, and is drawn by a single led horse. A special class of reservists is designated for service in the Red Cross Society's hospitals.

BULLETIN OF THE NAVAL MEDICAL ASSOCIATION OF JAPAN.

The May issue of this well illustrated publication, for the most part printed in the Japanese character, contains a summary in English of its contents, which includes three cases of lymphatic leukæmia; a rare sequela of gastro-enterostomy; and on solitary tuberculosis of the iris and its treatment. In a paper on the von Pirquet's and Calmette's reaction and some clinical observations on tuberculosis the author, Staff-Surgeon R. Takamiya, referring to a report that a large number of tubercular patients have decayed teeth owing to waste of calcium, says that 101 out of 135 patients with this disease observed by him had decayed teeth.

MEDICAL PRACTICE UNDER THE INSURANCE ACT.

(BY OUR SPECIAL COMMISSIONER.)

(*Continued from p. 955.*)

XXII. (*continued*).—HULL: UNSOLVED DIFFICULTIES.

AT Hull, as in so many other places, the general impression is that "a better fight will be put up next time, for the profession has learnt a lesson." Thus is defeat acknowledged, the necessity of union and discipline proclaimed, and the belief expressed that other contests are likely to occur at no very distant date. When I inquired what was the nearest danger in sight, the general opinion was that a dispute would surely arise if the insurance fund is made to pay for medical attendance for insured persons who are temporarily absent from their own area. At Hull the Medical Committee has passed a resolution refusing to consent to, and protesting against, any deduction being made from the insurance fund so as to form a central fund for such a purpose. Nor will the Medical Committee hear any mention of what is called case values. These vary far too much, and some might represent large sums. It is maintained that there is no power to enforce reductions of the amount the panel doctor is to receive, because some of the insured persons on his list go off in different directions for their holidays. If they can afford holidays, it was said, they can afford to pay the usual fees to the local practitioners at their holiday resorts. None of these plans, nor any other plan to make deductions from the 7*s.* for this purpose, it is thought, could be enforced by law. In any case, this is one of the questions about which it may be necessary to "put up a good fight." Then there are a number of small questions that must be decided in one way or another and over which disputes may well arise. Thus, if a midwife sends an emergency call to a medical man in a maternity case, however complicated the accouchement may prove, he cannot charge more than 15*s.* Last March protests were made, but the Insurance Committee insisted that not more than 15*s.* could be allowed, even if it happened that two or three medical men had been called to one patient. Then even this small fee has to be claimed within 24 hours. In many cases the lowest amount that could be considered adequate remuneration was 2 guineas, for when such emergency cases occur it means that the medical attendant may have to make many calls after the child is born, and the 15*s.* never suffices for these subsequent visits. Therefore, the question arises whether the receiving of 15*s.* from the maternity benefit debars the medical attendant from claiming the rest of his account from the mother. Many medical men know nothing about the regulations, therefore they fail to send in their account within the 24 hours, and thus lose the 15*s.* No regulations had ever been sent to them. The Commissioners have been applied to in regard to these matters and some measures must be taken, for it is quite certain that exceptionally difficult maternity cases cannot be undertaken for a fee of only 15*s.*

Socialist Practitioners and the Act.

In regard to the Act itself, the profession at Hull were absolutely united on the economic basis of resistance to the proposed 4*s.* 6*d.* But when this offer was raised to 8*s.* 6*d.* the opposition weakened. Such as it was, it concentrated in the hands of the British Medical Association, and some practitioners who had left the Association because further struggle seemed useless rejoined it in the idea that it was about to become a fighting trades union. When, however, the larger sum was offered, several practitioners began to favour the Act, and the fact that they were strong Liberals, in some cases, suggested that party politics were now playing a part. But, on the whole, politics did not interfere with their loyalty to the majority of the British Medical Association division, which includes the East Riding of Yorkshire. Two well-known general practitioners at Hull are active Socialists, and it was interesting to note their attitude. They were opposed to the Act, considering that it must tend to weaken trades unions. They object to it because the Act interferes with the power of the trades unions to borrow, on behalf of their strike funds, money subscribed for their benefit funds. Then they regard the Act as reducing the status of the

medical practitioner; it interferes with his freedom, makes a sort of servant of him, and yet does not give him the status of being a State servant. The panel doctor is tied down to stated hours, a semi-State service having been instituted with all the disadvantages and none of the advantages of a genuine State service. Even in the time of year when, as an independent practitioner, it was possible to make arrangements and absent himself occasionally, the panel doctor is to-day obliged to remain at his post, though there is little or nothing for him to do. In its dealing with the people they consider that the Act tends rather in the direction of giving doles to the poor instead of raising the worker by teaching and encouraging him to organise. The insured workers are separated by the Act from the rest of the community. They are labelled and docketed. To the Socialist practitioners the Act appears as a disintegrating measure which, in practice, will tend to weaken the force of those labour organisations, especially the trades unions, that are best able to defend the cause of the workers.

How the Profession Accepted the Act at Hull.

Up to December, 1912, the profession at Hull were quite united in opposing the Act, but at the end of the year when at a meeting a vote was put there were 38 practitioners who voted for and 83 against the Act. Thus it was evident that quite a large minority had been won over and favoured the measure. There were signs of weakening in all parts of the country, particularly as the importation of whole-time men appeared to be more practicable than had been believed possible. Many practitioners who felt they would certainly lose nearly all their practice began to waver, and the remnants of resistance entirely disappeared when, at Christmas, the misunderstanding arose concerning the proposition to negotiate directly with the Friendly Societies. Everyone felt most keenly in regard to the emancipation of the profession from the control of the Friendly Societies and medical aid clubs. No one understood that it had not been proposed to negotiate with the Friendly Societies, but only to entrust them with the collection of subscriptions, while everyone in Hull remembered well what had been meant by subservience to the Friendly Societies.

An amusing episode now occurred. It having been ascertained by the vote recorded above that there were 38 practitioners in favour of the Act, an attempt was made to gather them together, but no one knew all their addresses. Therefore, an advertisement was inserted in the papers; but the printer removed a comma, so that it appeared as if all the members of the profession were invited to the meeting instead of only those who were in favour of the Act. The resulting discussion, as may be imagined, was at first somewhat heated, but eventually those present had a quiet talk, which ended harmoniously by those against the Act passing a vote of thanks to those in favour of the Act for having convoked the meeting. The supporters of the Act pointed out that before the local division of the British Medical Association had decided to oppose it they had passed by a large majority a resolution that "this division would not refuse to work the Act." Thus, instead of refusing, they then left the matter open. By the time other meetings were held the feeling of antagonism to the Act had developed and continued till the end of 1912, but then the decision to fight the Act was reversed. A big majority are now thoroughly in favour of the Act and hope that the terms will be made better step by step as opportunity arises. For instance, the question of mileage round and about Hull has to be settled, for some practitioners have suffered considerable loss through long-distance visits. Still, when in April, 1913, after three months' trial, the question was raised whether the Hull medical men would continue working the Act, not a hand was held up against it.

Need of Meetings and Discussion.

Though the main issue is thus settled, there should, nevertheless, be frequent meetings of the profession. Some months of experience have been acquired concerning the working of the Act, and its difficulties and remaining defects could now be discussed with advantage. Amendments and improvements are still needed, and something must be done to give articulate expression to what is desirable and desired. This is all the more easy, as, after making several inquiries, I think it may be said that there does not remain in the ranks of the local profession any resentment or bitterness of feeling. Correspondence in the lay papers shows that such feeling is not dead everywhere—and I am not wholly surprised that this should be the case—but Hull is spared the troubles of abiding rancour. Though some practitioners have suffered a little by losing patients, the great majority are at present enjoying an increase of income, and this tends towards friendliness. But one grievance which I have noticed in so many towns occurs at Hull as elsewhere. There are many sons and grandsons of wealthy persons who, because they are employed, are insured and claim medical attendance at the contract rate where formerly they paid, and could well afford to pay, full fees.

The Poorest Panel Practice.

A great deal remains to be done to endeavour to equalise the conditions of panel work. Thus, at Hull, I was informed that a practitioner has on his list about 800 picked lives belonging to a very decent class. As a result, there is so little illness among them that, dividing the 800 annual 7*s.* by the number of consultations given, he received 3*s.* 6*d.* per consultation. On the other hand, another practitioner has 1600 to 1700 insured persons on his list. They are not, however, specially selected, but, on the contrary, belong to the worst class, and he calculates that he only obtains 1*s.* 6*d.* per consultation or item. If the system of payment was according to the work done, the poorer the class of insured persons the larger might be the income. Thus the contract system may provide proportionally the largest incomes to those who do the least work. This anomaly prevails all over the country. Then—and this concerns more especially very poor practice—there is the altered attitude observed at the hospitals or infirmaries. In many such establishments help is refused to those who can be treated by a panel doctor. Very few medical cases are taken at Hull unless they are admitted as indoor patients; small wounds may be dressed for the first time at the hospital, but after this first care the injured person is told to go to his panel doctor. The result is that, in the poor practice mentioned above, there are a large number of insured persons, notably dock labourers, who need treatment for minor injuries, such as cut hands, sprained ankles, &c., stitches have to be removed, and new dressings put on. There is no difficulty in such work, but it takes a great deal of time. There are not many panel doctors who can afford the services of a nurse; and then, instead of merely writing out a prescription, it is necessary to get hot water, a basin, bandages, antiseptics, &c.; thus a good 15 minutes may well be spent over the dressing of some small injury, especially if this is done in an inadequately equipped surgery with no nurse to help. Previously to the Act, in the days of club practice, all such patients went to the nearest hospital. But there are also some more serious cases that come to the panel doctor. Thus the practitioner, with the large panel practice I have mentioned, had on his list of injured persons two cases of broken legs and a fractured collar-bone. For the latter he had given, out of his own pocket, 10*s.* 6*d.* to get a suitable strap and buckle arrangement. Of course, he was not obliged to spend this money, but it would have been difficult otherwise to treat this particular patient. Then there were two men who had fractured ankles. Few such cases came as club patients before the passage of the Insurance Act. It is just this difference, not between one practice and another, but between the different panel practices, that will need better adjustment. In all the great and poor panel practices there are many slum dwellers, dock labourers, factory girls, casual labourers—underpaid, half-starved, badly housed men and women. The majority of these people do not think either of what is being done for them or of what used to be done. They grumble because they have to pay their share of the insurance money, yet the Act is proving to be of great medical advantage to them. Among this very poor section of the community there are not many who used to belong to Friendly Societies or medical aid clubs. Therefore, for the first time in their lives, they are paying for medical attendance. When to what they themselves give are added the employers' and the State's contributions, it will be seen that some medical men are receiving payment to-day from sections of the community which formerly were attended for nothing or went to charitable institutions. As often as not, these people had no medical attendance at all, whereas now they are receiving competent advice and treatment.

This, in time, must bring about a considerable improvement in the condition of the lowest and the poorest.

Wages and the Act.

At Hull, as elsewhere, there is of course the problem of malingering, and the desire for the establishment of a medical referee was expressed in several quarters. The panel doctor has not the time to play the part of a detective, especially if he has a large list and his waiting-room is crowded with impatient sufferers. The man with the pain in the back who says he cannot stoop or carry would have to be stripped and examined and put through a great variety of tests before it could be ascertained whether he was malingering or not. It stands to reason that sometimes, if the practitioner is over-worked, his story being probable, is believed without much testing. The greatest difficulty is with women and girls, because their wages are so low. For instance, I came across a charwoman who never earns more than 1*s.* 6*d.* a day and a little food, but as she is not employed every day her income hardly exceeds the 7*s.* 6*d.* a week she would receive as sick allowance under the Act. It often happens with badly paid women and girls that life is more enjoyable on their sick allowance with nothing to do than when working hard to earn about the same sum. Then, as these unfortunate women are very susceptible to illness as a natural consequence of the hard lives they lead, it requires very little malingering, a mere exaggeration of symptoms, to get on the sick-list. Thus better wages become an essential condition to the successful working of the Act. Also, it must be borne in mind that the general standard of health will decrease as less robust persons come into the scope of the Act, so that there will be more to do, and yet there is to be no increase in the payment. The profession is insisting on adequate terms for dependents, so that there should be a good precedent to work upon should an attempt be made to bring them into an enlarged insurance scheme. To-day the profession is undoubtedly receiving more money than was the case before the Act, but will this continue if other sections of the community are also forced to insure?

(To be continued.)

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Housing Acts in Scotland.

SOME valuable hints on the provision of houses by local authorities have been published by the Local Government Board of Scotland. They have not been formally issued to the local authorities, but can be obtained from the Board on application. It is pointed out that either common lodging-houses or separate dwellings (including cottages and gardens) may be provided within or without the district of the local authority, and that there is no statutory restriction upon the class of house that may be erected, provided that it is for habitation by the working classes. But a local authority should first satisfy themselves that there is an unsatisfied demand for working-class houses, and that such are not likely to be provided by private enterprise, and should also consider whether they can do anything to stimulate private enterprise by drawing attention to the scarcity of houses, by feuing municipal land at a cheap rate, or by developing this land by forming roads and laying sewers and gas and water mains in advance. No selected site should be purchased until the Board's consent has been obtained to borrowing, and urban or built up sites should be avoided on the score of expense. Discretion is given to a local authority to acquire land either by agreement or by compulsory powers under Section 2 of the 1909 Act. In the preparation of plans a careful regard should be had to local conditions and to the requirements and means of the prospective tenants, while studied attention should be given to the "Memorandum of the Local Government Board on the Provision and Arrangement of Houses for the Working Classes." It is recommended that sketch plans should be submitted informally to the Board's architectural inspector before they are finally adopted by the local authority. The consent of the Board is required to loans for building purposes, and the maximum periods of repayment advised by the Board are (1) 60 years for houses (with shorter terms for roads, drains, fences, &c.) and (2) 80 years for land. Either the annuity or instalment system of repayment may be adopted. If feasible, housing schemes should be on a self-supporting basis, though the Board do not make this a condition of their consent to borrowing.

Glasgow Parish Council and the Treatment of Phthisis.

For some years there has been a considerable diversity of opinion in Glasgow as to the relative responsibility of the parish council and the corporation in the matter of dealing with patients suffering from tuberculosis of the lungs. At a conference held in 1906 the corporation and the parish council were agreed that phthisis should be included as a notifiable disease under the Public Health Act, but little was done until the year 1908. At that time the Local Government Board drew attention to the respective obligations of local authorities and parish councils, and indicated that the local authority should bear the whole expense, even if, until other arrangements were made, the parish council hospitals were utilised. In 1909 the corporation adopted the principle of compulsory notification, but since then they have done little to carry out their responsibilities. The parish council some time ago proposed to take a test case to the Court of Session, but this was deprecated by the Local Government Board, and further efforts were made to get the corporation to assume the burden of costs. At the present time there are over 400 patients suffering from phthisis in the institutions of the parish council, costing about £30 per year each, equivalent to an annual expenditure of £12,000. All this has to be borne by Glasgow ratepayers, whereas if the corporation or public health authority paid this annual cost the sum of £6000 would be saved to the city, because under the new tuberculosis maintenance grant one-half of the expenditure by the local authority on tuberculosis would be repaid out of Government funds. On the other hand, as things exist at present, no contribution is made to parochial authorities. The parish council naturally feel that money is being lost in this way to the city ratepayers, and they are making another effort to force the local authority to take up the question. The corporation also have apparently decided that the time has come for them to move in the matter, and it is a step in the right direction that was taken when last week the health committee of the corporation recommended the purchase by the corporation of Bellefield Sanatorium. This sanatorium was opened in 1904, and conducted by the Glasgow and District Branch of the National Association for the Prevention of Consumption. The sanatorium, situated in Lanarkshire, provides accommodation for 52 patients. The suggested purchase price is £7500 to £10,000 for the sanatorium with all fittings as it stands, and to this suggested agreement certain conditions are to be attached by the corporation as to the money being used directly or indirectly by the association in behalf of persons residing in the city of Glasgow suffering from tuberculosis. At the present time also an extension is being made by the corporation to Ruchill Fever Hospital for the treatment of phthisical patients, and it has been arranged that the small-pox hospital at Robroyston, when occasion permits, shall be used for the same purpose.

Memorial Portrait to a Dundee Practitioner.

On Sept. 24th a memorial portrait to the late Dr. George Lawrence, who died last year, was unveiled at the Dundee Art Gallery. The portrait has been painted by Mr. W. B. Lamond, and bears the following inscription:—

George Lawrence, M.B., C.M. Born 1871; died 1912. Presented to Dundee Permanent Collection by grateful patients and friends to mark their appreciation of valuable services to the community. September, 1913.

Sept. 30th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Health of Belfast during 1912.

THE report of the medical officer of health of Belfast for the year 1912 is fuller, more complete, and more satisfactory than any of its predecessors. The statistics in the report are based on a population of 391,974, as estimated by the Registrar-General in the middle of the year. In 1912 the birth-rate was 27·8 per 1000, being 0·6 less than in 1911, and it was, as might be expected, highest among the inhabitants of working-class districts, and lowest among those resident in the better class areas. The death-rate per

1000 was 18·1, which is 0·9 higher than in 1911, but 1·5 lower than the average rate for 1902–11. Of the total deaths (7111) there were 1408 in children under 1 year of age from all causes. Respiratory diseases, including pneumonia and pulmonary tuberculosis, caused 2592 deaths—i.e., 802 from pulmonary tuberculosis, 799 from pneumonia, and 991 from other diseases of the respiratory system. 338 deaths were from forms of tuberculosis other than pulmonary, 317 from cancer, 217 from whooping-cough, 171 from measles, 159 from diarrhœal diseases, 48 from scarlet fever, 37 from diphtheria, and 17 from typhoid fever. If, as Dr. Arthur Newsholme teaches, "infant mortality is the most sensitive index we possess of social welfare and of sanitary administration, especially under urban conditions," then the rate in Belfast—129 per 1000 births in 1912—demands some consideration. Mr. H. W. Bailie, the medical superintendent officer of health, seems to hit the great cause when, on p. 54 of his report, he says: "There can be no doubt that the removal of all insanitary conditions improves public health generally, but more particularly that among infants, by the prevention of accumulation of refuse, the breeding places for flies." In Belfast house refuse is removed only once a fortnight. Mr. Bailie suggests in his report "that more frequent removals of house refuse be undertaken, particularly during the summer and autumn months," and he draws special attention to "the existence of hundreds of back passages which require to be paved, drained, and completed, as in their present condition they are a menace to public health." If the plan in use in so many Scotch and English cities were adopted in Belfast—that is, the compulsory use of house-bins and their frequent emptying—the infantile mortality would in all likelihood decrease. It takes those carriers of disease—the flies—a week to come to maturity in their growth, and this pest would be combated by the prompt removal of house refuse. As in many other cities, the death-rate from pneumonia in Belfast keeps very high; in 1912 there were 799 deaths from this disease, being 331 in excess of the number in 1911. Is it not time that a campaign was started against this modern urban cause of mortality? One of the special facts brought out in the report is the continued prevalence of scarlet fever, which commenced in an epidemic form in Belfast in the middle of October, 1909. In 1910 there were notified 734 cases of scarlet fever, in 1911 the number was 766, while in 1912 it has risen to 916 (an attack rate of 2·3 per 1000). That is, in three years (1910–11–12) in Belfast 2416 cases have been notified. In 1912 the disease was prevalent during the entire year, but most so in the last four months. There were 48 deaths, which gives a mortality-rate of 5·2 per cent. of those attacked—a fact indicating that in a number of cases the type of the fever was virulent. It is regrettable to find that the epidemic has remained during 1913.[1] In the epidemicity of scarlet fever Belfast is having the same experience as many English cities, and the problem of such a long-continued epidemic has not yet been solved. This medical report of Mr. Bailie is a most welcome one, indicating, as it has done, that the public health department of the City of Belfast has in recent years been greatly improved; and any friendly criticisms made are simply in the direction of trying to improve the public health of the great industrial and commercial city of Ireland, of which its inhabitants are justly so proud.

Medical Advisers to Insurance Committees.

The secretary of the Irish Medical Committee has sent a circular to the members of the medical profession in Ireland drawing their particular attention to the following resolution which was passed at the last meeting of the Irish Medical Committee:—

> That every consultant should ask the medical man who calls him in if he be a "medical adviser," and in case of doubt should confer with the local secretary of the district, so that the consultant may exercise his option of refusing to meet such a man in consultation.

There is no doubt whatever that in some quarters the feeling against the institution of these appointments is very strong.

King Edward VII. Memorial, Belfast.

At a meeting of the executive committee of the King Edward VII. memorial, which is to take the form of a new block at the Royal Victoria Hospital for X ray and vaccine therapy, held in the City Hall, Belfast, on Sept. 23rd, the contract for the building was given to the same firm which built the new hospital. The contract will amount to about £14,000, and there is an additional £4000 in reserve for furnishing.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

A Suggested Cause of Appendicitis.

A THEORY has recently been advanced which attributes to drinking water a causative rôle in certain obscure cases of appendicitis. It is a remarkable fact that in a family of 16, six who drank only water had to be operated on while the rest escaped. Appendicitis has certainly notably increased, especially in the well-to-do classes, since water-drinking became fashionable—i.e., within the past 25 years. Is this to be ascribed solely to an increased precision of diagnosis? Does water contain a hitherto unrecognised microbe of appendicitis? Since many of the patients drank only mineral water or germ-free fluids, it must be a question not of what water supplies, but rather of what it does not remove or destroy. The researches of Professor Sabrazès and others have shown that unsophisticated wine may be regarded as a good antiseptic—as also may cider, beer, and soured milk—in the absence of which the intestinal microbes germinate freely. Appendicitis might be the occasional result of this free germination. Professor Jalaguier, whose statistics are numerous, maintains an open mind, for his operation cases are divided equally between the two classes. But it must not be overlooked that there are many kinds of appendicitis, even tuberculous and cancerous, and that these arise from a variety of causes. In any case the hypothesis in question, based as it is on a wide collection of facts, appears not without point and calculated to assist in the rehabilitation of wine to its proper place.

Tuberculosis of the Aged.

Dr. Baudet seeks to show that tuberculosis of the aged is much more frequent than is commonly supposed, a fact of importance from both a family and a social point of view. In the Department of the Seine in ten years 12,293 aged persons died from tuberculosis, so that 5·53 per cent. of old people in Paris who died must have been tuberculous. The danger to society from this frequency is greater because the aged subject of tuberculosis usually presents the open form with cavities, and because in such subjects the tuberculosis is very often unrecognised. Dr. Baudet adduces examples of these sluggish pulmonary infections, progressing silently without either the patient or the medical man suspecting it. This frequency of unrecognised tuberculosis affords an explanation of cases frequently observed by medical men in which families seem particularly predisposed to phthisis. Dwelling with an aged relative in apparent good health, children of all ages one after another fall victims of the infection, or if they do not die are attacked with Pott's disease, a white tumour, or a bacillary orchi-epididymitis. This aged relative, sharing the overcrowded miserable lodging, goes out but little, fearing to catch cold, but spares neither kisses nor caresses to the little ones, and often sleeps in the same room with them. It is not to be wondered at that she coughs somewhat, easily gets out of breath, and "catches cold" from time to time, without the least suspicion arising as to her connexion with the recurring deaths. These facts show that the measures of disinfection ordained after a death should not be restricted, as is the case under the present law, to the cases of those who died between 2 and 60 years of age. Aged or not, known or unknown, such tuberculous subjects disseminate contagion much more than those actually sick, and those about them do not take precautions against a condition which does not appear serious or the nature of which is unrecognised. Finally, it must be remembered that even though the child is not born tuberculous he is born particularly "tuberculisable," and it is contrary to the interests of society not to remove the newly born from such a serious menace to disease and death.

The Treatment of Burns by Heliotherapy.

Dr. Aimes has had remarkable success in the treatment of burns, recent or otherwise, by the action of the sun. The sun acts on burns bactericidally, destroying the germs by

causing active vaso-dilatation which creates a focus of vitality highly favourable to tissue repair and obnoxious to micro-organisms, by its analgetic action, by the formation of a protective pellicle, and by promoting cicatrisation. The technique is easy. Heliotherapy may be purely local or regional, it may be direct without the interposition of glass, of gauze, or of fatty bodies. Insolation should be administered in progressive doses, the head being always protected from the rays.

The Treatment of Hydrocele by Formol.

M. Morestin has again directed the attention of the Société de Chirurgie to a mode of treatment already advocated by him, and one which seems likely to replace the use of iodine injection. Take the case, for instance, of a one-sided ordinary hydrocele of medium size, with walls supple and uniformly thinned, and containing a completely translucent fluid. The subject lies on his back and the scrotum is lightly painted with tincture of iodine where the puncture is to be made. Anæsthesia, either local or general, is unnecessary, and, moreover, there is no occasion to remove the hair. Taking up the tumour in one hand, M. Morestin inserts in its upper part the needle of a Pravaz syringe. When the needle is fully inserted, its mobility in the cavity is made sure of. A little lower down a trocar is quickly inserted, and nearly the whole of the fluid is evacuated. When the cavity is almost entirely emptied the trocar is withdrawn, and through the Pravaz needle M. Morestin injects 2, 3, or even 4 c.c. of a mixture of equal parts of formol, glycerine, and alcohol. The needle is then withdrawn, and the fluid is caused by light massage of the scrotum to penetrate the recesses of the cavity. No dressing is necessary. The patient remains in bed or not as he pleases. The injection is hardly painful, and the consequent reaction causes very little pain, often none at all, although it is considerable; for the scrotum swells and becomes œdematous, without, however, showing any of the inflammatory reddening usually seen after the injection of iodine. After two or three days the swelling reaches its height. The greater part of the time the patient can get up without experiencing anything worse than weariness. The general health does not suffer, and the patient is deprived of neither appetite nor sleep. In three or four days retrogression begins and takes place rapidly, being finished in from three to five weeks. Long before this time the patient can resume his ordinary life.

Sept. 29th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The International Congress on First Aid and Ambulance Work.

THE month of September, 1913, will be long remembered in Vienna as the month of scientific congresses, the two most important, from a medical point of view, being the Congress of German Naturalists and Medical Men and the International Congress on First Aid and Ambulance Work. With the first-mentioned one, which was also the larger of the two, were combined the annual meetings of the German Dermatological, Pædiatric, Psychiatric, and Laryngo-Otological Societies. The International Congress on First Aid and Ambulance Work was held here from Sept. 9th to 13th. The number of enrolled members was over 1200, and no speaker was allowed more than 15 minutes, in order to enable the business to be completed within the stipulated four days. The Congress was an interesting manifestation of the achievements of the modern spirit of pity for those who may be in danger or distress, and Austrians might justly feel patriotic satisfaction on finding that their country was foremost in many respects as regards this subject. Apart from the social entertainments, which the representatives of the inviting city and country seem to regard as indispensable, the actual work done in the sections was extensive enough. The papers read before the Congress had to be presented under one of the following ten heads: first-aid in accidents, instruction of non-medical persons in first-aid, first-aid in towns and in country places, first-aid in travelling (with subsections devoted to automobiles, railways, and aeronautics), first-aid on the seashore and on the high seas, first-aid in mining industries, first-aid in conflagrations, in mountaineering, and in sport, and finally the prevention of accidents generally.

Practical Demonstrations in First-aid.

An interesting practical demonstration on first-aid on a large scale was presented to the Congress and the population generally by the Vienna Rettungsgesellschaft (Ambulance Corps). A test alarm was given to the effect that an accident had happened at the racecourse, that some 40 or 50 persons required immediate help because a wooden platform had given way under a mass of spectators, and that many victims had also been trampled on by horses and a panic-stricken crowd. A few minutes after the message arrived an ambulance detachment, consisting of 20 cars, with one medical man and one male nurse on each of them, made its appearance at the scene of the supposed disaster. Boy scouts acted the part of the injured. The methods of first-aid, the bandages ready for use for such cases, as well as the method of distributing the patients to the nearest hospitals, were demonstrated. To each supposed injured person a small board was attached giving information to the hospital staff of the nature of the injury and the treatment adopted, thus enabling the case to be promptly dealt with at the surgical station. A very similar demonstration of life-saving in the water was given a little later, when the methods of bringing out of the water a person unable to swim and of resuscitation of the apparently drowned were practised. The British Royal Humane Society served here as a model for the establishment of a society for first-aid in shipwreck, floods, attempted suicide by drowning, &c. As a matter of fact, it happened by a curious coincidence that just at the time of the demonstration a candidate for self-destruction wanted to drown himself at the scene of the proceedings. Needless to say, his attempt was promptly frustrated.

Exotic Diseases.—Life-saving at Sea.

The Transactions of the Congress contain many interesting papers. The danger of diseases epidemic in Asia being imported into Europe by the continuous stream of Mahomedan pilgrims returning from the hotbeds of plague, cholera, and small-pox in Arabia, was discussed by Dr. Kobler, the head of the Board of Health of Bosnia and Herzegovina. Since the completion of the railway between the Mahomedan holy places and Damascus the quarantine formerly provided by the caravan journey of a week's duration has been lost.[1] The journey now lasts only a few days, and European countries with Mahomedan populations must be on the alert and must provide special pilgrim stations on the frontier for all suspicious cases.—The prevention of loss of life in sea voyages was discussed in a paper by Professor Flamm, who said that watertight compartments should be constructed in the long axis as well as in the cross section of a modern ship, the stability of the vessel being of paramount importance. The number and capacity of the life-boats should be in direct relation to the number of persons on board the ship, and not to the tonnage of the vessel. A modern passenger steamer must have apparatus for wireless telegraphy, must be carefully ballasted by proper storing of the cargo and trimming of the fuel, and must have the fuel stored in fireproof compartments. Medical aid must be provided for each 300 or 500 souls, one medical man and a ship's hospital or ward, with at least six beds, being available. Cork belts must be within easy reach in the berths and on deck.

First-aid in Mountaineering and Aeronautics.

The organisation for first-aid in mountaineering is interesting, and for it thanks are due to the German and Austrian Alpine Society. The paper by the representative of this society gave particulars of the network of ambulance stations spread over the mountains of these countries (mostly the Alps). There are over 200 first-aid outfits distributed amongst them for emergency cases, and the services of a large number of voluntary helpers, as well as of paid officials, have been secured. They chiefly form rescue or search parties, and are supplied with ropes, ladders, and hammocks. Each station contains a first-aid chest, with splints, medicines, stretchers, bandages, and several small first-aid outfits for the authorised mountain guides. These latter have to attend Samaritan classes, where medical knowledge necessary for them is obtained. The Alpine danger signal is now adopted as an international signal, and the recognised guides are trained to deal with the ordinary accidents met with in the mountains, such as snow-blindness, frost-bites,

[1] THE LANCET, 1908, vol. i., p. 1799; vol. ii., pp. 971, 1104, 1248, 1405.

and fractures. Thanks to the efforts of the above-mentioned society many lives have been saved within the last decade by the activity of these courageous mountaineers.—Aeronautics have received much attention of late from the medical standpoint on account of the great danger to life or health. Mr. Hinterstoisser, of the Army Aeronauts, stated in his paper that first of all smoking near an airship or aeroplane was distinctly criminal. Nobody should rush to the place where any air craft was preparing to descend. Medical attendance should be obtainable within an easy distance of an aerodrome, and a portable first-aid outfit should be ready at hand, as well as fire-extinguishing apparatus. Persons with an unstable circulatory or respiratory system should not meddle with aeronautics, and perfect hearing was also necessary for a would-be airman.

First-aid in Alcoholic Intoxication.

A good paper was devoted to first-aid in cases of serious alcoholic intoxication. Hitherto the majority of such persons have been dealt with by the police in a decidedly offhand fashion, the attendance of a qualified medical man being deemed unnecessary. Serious mishaps, however, have occurred now and then, with disastrous results to the patient, when bodily illness or injury has been mistaken for alcoholism and treated as such. Every person found helpless in the streets and suspected of alcoholic intoxication should therefore be put in special "awakening wards" and examined by the police surgeon. The coma of alcoholic intoxication was not less dangerous, it was explained, than coma due to any other cause, and responded better to correct treatment.

First-aid after Explosions in Mines and at Fires.

First-aid after explosions in mines was the subject of another interesting paper. The composition of the explosives used for blasting purposes was said to have a direct relation to the vitiation of the air in mines. Harmless by-products are formed in the combustion of several of the newer explosives, which in Austria are a monopoly of the Government, and are not allowed to be extensively employed. Various unfortunate incidents have led to very elaborate life-saving appliances being constructed and kept in readiness for use in this country. An exhibition of smoke-caps, electric search-lights to be carried on the head, and similar first-aid apparatus for mining disasters, including a fireproof suit of clothes, with airtight headpieces, an air reservoir, and chemicals for the removal of carbon dioxide from air which was to be breathed again, was much admired. A similar exhibit of the Vienna fire brigade attracted much attention. The latter comprised fireproof ladders, ventilators, and electric lights for use in buildings filled with dense smoke, whilst the Vienna Rettungsgesellschaft showed its portable kitchen for feeding people left without resources after great conflagrations and similar calamities. This kitchen outfit did excellent service at the scene of the memorable earthquake of Messina, when thousands of destitute survivors were dependent upon it for their daily meals.

I intend to send you a further account of this interesting meeting.

Sept. 29th.

ROYAL ALBERT INSTITUTION, LANCASTER.—The ninth quinquennial festival will be held on Tuesday, Oct. 21st. The annual general meeting will be held in the De Vitré Hall at 11.30 A.M., under the presidency of Lord Richard Cavendish, chairman of the central committee. The institution, with the schools and workshops, will be open for inspection from 10.30 to 12.30. The presentation of long-service medals will be made by the Lady Moyra Cavendish at 12 o'clock. The medical superintendent, Mr. Archibald R. Douglas, will receive a gold medal for 17 years' service. The Countess of Derby will open the new Farm Colony Building at 12.30 P.M., and an address will be given by Mr. A. H. Trevor, Commissioner in Lunacy. A public meeting will be held in the De Vitré Hall at 2.15 P.M. under the presidency of the Earl of Derby, G.C.V.O. Addresses will be given on The Feeble-minded: Historical Retrospect, by Sir T. Clifford Allbutt, Regius Professor of Physic, Cambridge University; on the Future of the Royal Albert Institution, by Sir James Crichton-Browne, Lord Chancellor's Visitor in Lunacy; and on the After-care of the Feeble-minded, by Dr. C. Hubert Bond, Commissioner in Lunacy.

Correspondence.

"Audi alteram partem."

THE LATE DR. FRANK BUSZARD.

To the Editor of THE LANCET.

SIR,—For 40 years Dr. Frank Buszard undoubtedly held the premier position amongst the medical men of the South Midlands, and his death has left a blank which it will take a long time to fill. I should like to add a few words to the brief obituary notice which appeared in THE LANCET of Sept. 20th. Dr. Buszard was born at Lutterworth 74 years ago, the son of Marston Buszard, who practised in that town for many years, and whose father before him had also been a medical man, so Dr. Buszard in a way was steeped in medical tradition. He was educated at Rugby School, afterwards joined Guy's Hospital, where he had a distinguished career, and there is little doubt that if he had remained in London he would have taken a very prominent place in medical circles. Fortunately for Northampton, he decided to enter for the post of house surgeon at the Northampton General Infirmary, as it was then called, and after a strenuous contest (for one had to canvass all the governors) he was elected, and for some six years he filled the post. In those days there was no assistant house surgeon; he singlehanded had to look after the surgical and medical wards, and as one or two of the honorary staff were aged he had a very considerable share in the treatment of the patients. He rapidly won the confidence of the public, and when at the termination of his house surgeonship he started in practice in Northampton he soon achieved success, and his position was an assured one. In 1876 Mr. Mash, the senior surgeon, retired, and Dr. Buszard was elected to the vacant post. In those days he was a bold and skilful surgeon, and took a very keen interest in ophthalmic surgery, in which he had had special training at Moorfields. In 1878 Dr. Francis, the senior physician, retired, and Dr. Buszard resigned the office of surgeon and became physician to the hospital, a position which he held till his retirement about a year ago, when he was appointed consulting physician. In these days of specialism I suppose it will be a long time before we shall come across a medical man who had such a wide and varied knowledge of disease. Added to this—and assuredly a tremendous advantage—was a fine presence, a most kindly way in treating patients, and an invincible optimism which often helped to tide patients over the most critical periods. Dr. Buszard was a gentleman in the truest sense of the word, and for some 30 years he had the cream of the consultative work in Northampton and some 20 miles round. When it was suggested by either the patient or his friends that Dr. Buszard should be called in, one always welcomed the wish, as the medical man felt that he was certain to be helped in every way. I do not know if I am right, but I always thought that Dr. Buszard had gained a great deal of his tact and judgment in treating patients from Sir William Gull, who, I believe, always regarded Dr. Buszard as one of his most distinguished pupils.

His interests were not confined simply to medicine; he was elected an alderman in 1881, retired from that position after a short time to fight a ward, when he was defeated, but shortly afterwards he was elected to another ward, and he held the position for 18 years. For the greater part of this time he was chairman of the public health committee, and most valuable services he rendered to Northampton in eradicating slums and improving the health of the people. He was very strong in his opinion that medical men should attempt to enter into public life, and always encouraged the younger men in their efforts to do so. He was a fluent speaker and a most capable debater, and I feel sure that I am stating a fact that when he left the Northampton town council it lost its most distinguished member. He was an ardent Conservative, often spoke at political meetings, and, though a strong partisan, his opponents always appreciated his keen and vigorous thrusts at their weak spots. For many years he was churchwarden of Dallington Church, and in the evening read the lessons. When I came to the town 30 years ago he was very devoted to lawn tennis and a very skilful player; this he kept up until osteo-arthritis crippled him

and prevented him from joining in a four-handed game. As a young man, when at Guy's and the Infirmary, he was an excellent cricketer, excelling as a bat, and in later years we were glad to see him often up at the county ground watching the performances of the county cricket team. In 1911 it was suggested that it would be an appropriate acknowledgment of his many services to present him with his portrait. The idea was taken up very eagerly by all classes, some 200 subscribed to the fund, and Mr. Harris Brown was chosen to paint the portrait and a replica. One hangs in the board room of the hospital, the other was presented to Mrs. Buszard at a gathering of the subscribers in a highly congratulatory speech by the late Marquis of Northampton.

Dr. Buszard's health failed very much during the past year, and in June he finally retired from medical work. About ten days before his death he was seized with gastric symptoms, renal complications occurred, and he passed away on Sept. 14th. He touched life at many points, and he will be long and sincerely mourned by all those who had the privilege of knowing him.

I am, Sir, yours faithfully,

Northampton, Sept. 29th, 1913. R. A. MILLIGAN.

THE NECESSITY FOR ACCURATE REGISTRATION.

To the Editor of THE LANCET.

SIR,—May I once more ask you for your valuable assistance in reminding members of the profession that, unless their names appear in the Medical Register, they are not "legally qualified medical practitioners" (Medical Act, 1858, Section 34), and that the duty of notifying changes of address rests with them. No person can—

hold any appointment as a physician, surgeon, or other medica officer either in the military or naval service, or in emigrant or other vessels, or in any hospital, infirmary, dispensary, or lying-in hospital, not supported wholly by voluntary contributions, or in any lunatic asylum, gaol, penitentiary, house of correction, house of industry, parochial or union workhouse or poorhouse, parish union, or other public establishment, body, or institution, or to any friendly or other society for affording mutual relief in sickness, infirmity, or old age, or as a medical officer of health, unless he be registered (Section 36).

And—

no certificate required by any Act now in force, or that may hereafter be passed, from any physician, surgeon, or licentiate in medicine and surgery, or other medical practitioner, shall be valid unless the person signing the same be registered (Section 37).

The Medical Register is the only official publication, and it should not be confused with any of the various directories which issue circulars annually. No one who is not familiar with the work of this office would believe the amount of trouble which is taken to keep in touch with practitioners, and to find them when touch has been lost, but, unless we are assisted by members of the profession themselves, our efforts are often fruitless.

In consequence of cases which have recently occurred, it becomes increasingly important every year that the Registrar should carry out the duty laid upon him under Section 14 of removing from the Register the names of practitioners with whom he cannot communicate. It is done with reluctance, but only by this means can the public and the profession be protected against impostors. No doubt cases of hardship do sometimes arise in consequence of this removal of names, but every possible source of information is made use of to save practitioners from the results of their own forgetfulness, and, if they are inconvenienced by finding that their names are off the Register, the blame does not rest with this office. The duty of notifying changes of address rests with practitioners; the registrar is obliged to send communications to registered addresses only, but the practice is to make use of every available source of information.

I therefore hope that all practitioners who have any doubt as to the accuracy of their address in the Register will communicate with this office without delay, and, if they will give their full names and qualifications in legible writing, it will be of great assistance to us. All communications will be duly acknowledged. Perhaps I may add that by a recent Regulation practitioners possessing medical and dental qualifications, if already on the Medical Register, may register in the Dentists Register, or *vice versâ*, for a reduced fee of £2 1*s*. instead of £5 1*s*.

I should like to take the opportunity of drawing attention to the following resolution adopted by the Council on Nov. 30th, 1911. It cannot be too strongly urged upon practitioners that in giving certificates they are recognised by law as members of a trusted profession, and that it behoves them to exercise the greatest possible care in the matter.

Whereas registered medical practitioners are in certain cases bound by law to give, or may be from time to time called upon or requested to give, certificates signed by them in their professional capacity, for subsequent use either in courts of justice or for administrative purposes: And whereas such certificates include, amongst others:—

Certificates:—

(*a*) Under any statute relating to births, deaths, or disposal of the dead;
(*b*) Under the Lunacy Acts;
(*c*) Under the Vaccination Acts;
(*d*) Under the Factory Acts;
(*e*) In relation to children or to excusing school attendance;
(*f*) In connexion with Sick Benefit, Insurance, and Friendly Societies;
(*g*) In connexion with workmen's compensation;
(*h*) In connexion with naval or merchant shipping;
(*i*) For procuring the issue of Foreign Office passports;
(*j*) For excusing attendance in courts of justice, in the public services, in public offices, or at ordinary employments;

And whereas it has been made to appear to the General Council from time to time that some registered medical practitioners have given and signed untrue, misleading or improper certificates of the above specified or other descriptions:

Now, therefore, the General Medical Council hereby give notice that any registered medical practitioner who shall be shown to have given any untrue, misleading, or improper certificate, whether relating to the several matters above specified or otherwise, is liable to be adjudged by them to be guilty of "infamous conduct in a professional respect" and to have his name erased from the Medical Register under Section 29 of the Medical Act, 1858.

I am, Sir, yours faithfully,

NORMAN C. KING, Registrar.

299, Oxford-street, London, W., Sept. 26th, 1913.

LORD KELVIN AND THE ETHER OF SPACE.

To the Editor of THE LANCET.

SIR,—In the restful radiance of these southern waters I have been reading in THE LANCET of Sept. 13th your comments on the ether of space in Sir Oliver Lodge's recent address to the British Association, and you have awakened a vivid recollection of an interesting conversation on the genesis and evolution of matter and kindred interests which I had with Lord Kelvin shortly before his death. I had at that time been speaking on the significance of radium emanation and helium, &c., in relation to solar energy, and time, and time estimates, in an address at the centenary meeting of the Geological Society on behalf of the College of Physicians, and on the occasion of our meeting Kelvin brought me an advance copy of a short but very interesting paper, entitled "Gravitational Matter," which may or may not have been published subsequently.

He explained that the first word "*given* a definite quantity" in the opening sentence, though a mathematical commonplace, was also applicable in the creative sense, and it was in response to my quotation from Milton, "Hard thou knowest it to exclude ethereal substance with corporeal bar," which led to the expression of his views on the interstellar medium. Kelvin considered the ether as an all-pervading agent, possessing certain definite attributes of which radiation and gravitation were evidence, and held that any theory of evolution or condensation of ether into gravitational matter would mathematically conflict with the condition precedent that such a medium should exercise no restraint on the perfect mobility of the matter immersed in it. He shrank from asserting that the ether had no "influence" on matter, and deprecated any objections to generally received views on the subject as "whimsical."

Lord Kelvin at that time seemed to stand sceptical or with suspended judgment at the assertion of elementary instability or transformation, and frankly resented the illogical notion of dissecting an atom, but nevertheless in the vast progress since established in our knowledge of matter and of the ebb and flow in universal attenuation and condensation he would surely have taken a leading part, especially perhaps assisting our understanding in the corpuscular character we are inclining to superimpose upon undulatory light, and perhaps imparting a new significance to the ether of space itself.

I am, Sir, yours faithfully,

MICHAEL GRABHAM.

THE CORRELATION OF BIRTH-RATES AND DEATH-RATES.

To the Editor of THE LANCET.

SIR,—In THE LANCET of July 19th last there appears a letter by Dr. Binnie Dunlop under the above heading. I desire to draw the attention of Dr. Dunlop to the birth- and death-rates of British Guiana for the last 30 years, since in this colony his contention appears completely wrong:—

Year.	Birth-rate.	Death-rate.	Year.	Birth-rate.	Death-rate.
1883	31·4	30·2	1898	29·6	33·9
1884	29·8	30·6	1899	28·7	29·1
1885	31·6	29·5	1900	37·8	26·1
1886	35·2	25·5	1901	35·9	23·6
1887	32·3	32·4	1902	33·4	28·1
1888	30·8	29·2	1903	29·1	28·9
1889	36·1	28·1	1904	30·3	28·8
1890	30·9	39·8	1905	33·6	27·4
1891	27·0	37·0	1906	32·9	28·8
1892	28·0	39·0	1907	28·3	36·9
1893	27·3	35·4	1908	27·3	30·8
1894	24·9	33·5	1909	29·3	30·0
1895	28·0	29·6	1910	27·5	34·4
1896	32·6	26·4	1911	28·8	31·7
1897	33·2	27·5	1912	33·1	29·2

I am, Sir, yours faithfully,

K. S. WISE,
Government Medical Officer of Health.

Government Public Health Department, Georgetown, Demerara, August 29th, 1913.

LOW-PRICED CLINICAL THERMOMETERS: A WARNING.

To the Editor of THE LANCET.

SIR,—The experiences hereinafter set out may serve as a warning to all who are interested in the purchase of clinical thermometers for use in institutions, where, owing to the large number of breakages, there is a natural desire to reduce the cost of these articles as much as possible.

On August 29th three dozen clinical thermometers, at 10*s.* 6*d.* a dozen, were received from a well-known firm of surgical instrument makers. In order to be tested they were all placed together in an upright position and were totally immersed in warm water. After five minutes, during which time the water was continuously agitated, the temperature indicated by each was recorded. The following are the readings in order of removal from the water: 99·4, 98·2, 99, 101·6, 101, 101·2, 98·8, 99·6, 101·6, 100·6, 99·2, 99, 100, 101·6, 99, 99·6, 98·2, 100, 100·2, 99·8, 98·4, 98·6, 99, 98·6, 99·8, 96·4, 99, 98·2, 100·8, 96·8, 98, 98·6, 101·6, 98·8, 99, 100.

These were, of course, returned to the vendors, who replied that they could not guarantee the accuracy of such low-priced articles, but they stated that they could supply really reliable thermometers at 18*s.* per dozen, which they would guarantee to one-fifth of a degree. Three dozen of these were accordingly ordered, and when delivered they were submitted to a similar test. For a given temperature the readings were as follows: 100·2, 100·8, 102·4, 102·6, 102, 101, 101·2, 105, 100·8, 101·6, 100·6, 102·2, 104·4, 104·2, 103·8, 105, 102·8, 104·8, 102, 98, 98·2, 99·6, 100·8, 103·6, 100·4, 102·2, 103, 103·6, 100·2, 99·2, 105·4, 99·4, 100·4, 102·8, 102, 102.

These in turn were rejected, and a third batch (of 18) were supplied. This time a representative of the firm, armed with two thermometers with Kew certificates, attended to witness the testing. As before, the thermometers were placed in warm water, and in addition the two certificated thermometers were also immersed. The latter indicated that the temperature of the water was 98·4. The other thermometers gave the following readings: 97, 95·8, 96·5, 95·7, 96, 96·2, 95·8, 96·5, 96, 95·6, 97, 96·2, 95·4, 97·2, 96·8, 97, 96·9, 97.

The test was then repeated with water that was rather warmer, the Kew-tested thermometers indicating a temperature of 105·2. The others gave the following readings: 102, 102, 101·5, 101·5, 102·2, 101·3, 103, 103, 103·6, 103, 103, 103·4, 102·6, 103·4, 101·4, 103·2, 101, 101·4.

The firm's representative retired crestfallen taking his thermometers with him. Up to the time of writing no further consignment has been received.

I am, Sir, yours faithfully,

J. BASIL COOK,
Medical Superintendent to the St. Giles Infirmary, Cleveland-street, W.

Sept. 24th, 1913.

THE SCOPE FOR POST-GRADUATE TEACHING.

To the Editor of THE LANCET.

SIR,—Some months ago there was published in the supplement to the *British Medical Journal* a list of minor operations which, in the opinion of the committee that had compiled the table, were all beyond the competence of the general practitioner to perform. The list occupied about three-quarters of a column, enumerating about 50 or 60 operations, and it undoubtedly constituted a damning indictment of the inefficiency of the general practitioner. Incidentally, it is also a fierce slur upon the schools which turn out uncompleted practitioners in such vast numbers every year to make good the waste caused by death and other causes. The general body of inefficient general practitioners is recruited by the qualified but incompetent graduate. That list was published in all good faith in the belief that a doctor in general practice had neither the skill nor the knowledge with which to undertake these operations—that he never had the competence, even at the moment of his graduation, nor had since then had the energy or the field on which to acquire such proficiency. The object of the committee in publishing this list was to support its claim for special fees under the scheme it was pressing upon the acceptance of the Government, but it stands in all its nakedness as the deliberate judgment of the heads of the Association upon the proficiency of the general practitioner. It cannot be supposed that the committee had the cold-blooded intention of wantonly insulting the general practitioner—as far as my reading goes no protest has ever been published in the journal—indeed, the schedule seems to have been received with general acquiescence as comprising pretty well everything in the surgical line that he is unable to perform with efficiency. It seems also to be commonly accepted as true that the general practitioner is not conversant with the developments that have attended the progress of medicine in late years. The technical methods employed nowadays in diagnosis and treatment, the investigations pursued in the modern laboratory, are all assumed to be beyond the ken of the doctor in general practice. It has become almost a habit to believe that he is as a rule inefficient both in his practice of surgery, his knowledge of medicine, and his skill in gynæcology. It would appear to be a case of judgment by default.

I believe the general practitioner is fully alive to his limitations, and is keenly anxious to remove the slur that attaches to the position he occupies in the profession. He does not lay blame on the school for turning him out incompletely equipped for the work he has to perform, but he looks round for a way by which he can proceed to make himself sufficient. Dr. C. O. Hawthorne, in his admirable address at the International Conference on Post-Graduate Medical Education,[1] indicates several paths by which the general practitioner in pursuit of this object may wend his way. Doctors practising in London and the provincial cities provided with schools seem to have abundant means within their reach for "the cultivation of efficiency," though Dr. Hawthorne regrets to find that these means "exercise but little influence on the local profession." It may be that the system of post-graduate education in existence at these centres does not meet the needs or the opportunities of the local profession. In my opinion the practitioner stands most in want of clinical experience—it is essential that he should see and handle cases, see applied the latest methods in diagnosis and treatment, witness operations, and have a short exposition on each case by the demonstrator. Set lectures are in my humble judgment a mistake as they take up too much time. The busy practitioner must have his instruction potted.

Whatever is being done for the city practitioner it will scarcely be denied that the country practitioner, exposed as he is to influences that all tend to mental stagnation and deterioration, has been left much to himself and

[1] THE LANCET, Sept. 6th, 1913, p. 707.

that he can rarely avail himself of the resources for the cultivation of efficiency which are said to be within reach of his more favoured brother in the city. Deprived as the great majority of practitioners is by the system of hospital staffing now in vogue of equal means by which practical knowledge of disease, its course and treatment, may be kept alive and developed, is it any wonder that some of us lag behind in our journey along the road of science? Post-graduate courses serve a useful purpose as occasional refreshers, but they cannot supply the pabulum which the practitioner not on the staff stands in lack of. The stimulus should not be applied at long intervals, but should be continuous and constant. There is no dearth of books and journals by which he can make himself acquainted with all that is being said and written, but he cannot see what is being done. He must be put in the way of actually seeing the practical application of all the newest methods of research and treatment; he must be given access to the practice of the local hospital. It may be said that he is free now to see the practice of the hospital of his town, but it must be admitted that there is no system or method in vogue by which the "local professor" can really derive instruction from the large amount of clinical material that is at present positively running to waste. A casual walk round the wards with the visiting staff does not fulfil the necessities of the situation. I am in full accord with Dr. Hawthorne in his plea that "the local hospital should take its part in the process of post-graduate education"; it should be a school to the doctors practising within its range of service. No doubt there are various ways in which this proposal could be put into action, but as a beginning I advocate the weekly demonstration. Each member of the staff should in turn undertake to give an hour of his time on a fixed day to a demonstration of cases, an *exposé* of some new method of treatment or diagnosis, or, indeed, anything he considers calculated to interest and instruct his audience of fellow practitioners. As Dr. Hawthorne points out, such a scheme would be of great value, not less to the giver than the recipient, and the former might consider that the intellectual benefit accruing to himself a sufficient recompense for his trouble, though I am inclined to think that the payment of a moderate annual fee would remove from the mind of the latter a possible feeling of pressure under obligation. Fees, I am confident, there should be, and if the objections of the staff to receive them could not be overcome the hospital funds should take them.

I have good grounds for believing that the general practitioner is to-day desirous of making himself thoroughly competent in his work, both for his own sake and for the good of his patients, and there is good reason to expect that he will greedily seize upon any suitable opportunities that may be put before him. A teacher is made, not born, and though no doubt some provincial hospital men will receive my suggestion with doubt and diffidence as to their ability to carry it out in their own sphere, I am sanguine in my belief that as practice brings confidence their efforts to rise to the situation will result in their achievement of the desired object.

I am, Sir, yours faithfully,

West Mersea, Colchester, Sept. 24th, 1913. B. HALL.

THE HONYMAN-GILLESPIE TRUST.

To the Editor of THE LANCET.

SIR,—I have reason to know that there is a good deal of misunderstanding in the medical profession with regard to the object and working of this trust, and I hope you will allow me, through the medium of THE LANCET, to make the whole position clear.

The late Mrs. Honyman-Gillespie, of Torbane Hill, Scotland, left in 1886 a certain sum of money wherewith to build a medical school where homœopaths could study with regular practitioners, and she added a clause in her will that no vivisectors should benefit by her money. As the first condition presented many difficulties, and also as the legacy was not large enough to found the new school, the judges in court decided that the trustees should allot two-thirds of the income to the foundation of a chair in orthodox medicine and one-third to the foundation of a chair in homœopathy, the provision against vivisection being carried out. The trustees consequently decided to create a lectureship in the regular practice in tropical diseases and to allow the homœopaths to choose their own subject.

The clause with regard to vivisection forbade the trustees to accede to any demands made by the universities or existing medical schools that the lectureship should be attached to them, and it was resolved that some religious institution should be asked to add courses of tropical lectures to their educational syllabus. The Central Body of the Young Men's Christian Association, at 186, Aldersgate-street, was accordingly chosen, and since 1908 courses of lectures upon tropical medicine have been delivered there every Tuesday afternoon during the winter.

I was asked by the trustees, as I had travelled extensively in the Tropics and had verified the discovery of Laveran's parasite of malarial fever in the Mauritius,[1] to relinquish my practice in Paris and take up this lectureship, to which is also attached a scholarship in tropical diseases research. The income is about £400 a year, £300 sure and another £100 to defray expenses. I am bound to deliver 40 lectures a year and to devote four hours a day to original research.

In order to reach missionary students in Oxford, Mansfield College has appointed me lecturer there, and every two years I deliver a short course of lectures to all who wish to come. The missionary students both in London and in Oxford are admitted free, and all others pay £1 1*s*. There are generally about 20 to 25 students at the London class; they are principally missionary students and missionaries on furlough, but we always have a few travellers or explorers and prospectors. Professor Cantlie, Professor Daniels, and Professor Newham have lectured to these students, and Sir Ronald Ross is going to take the chair at the opening of this winter session.

My desire to do original research in return for the scholarship led me last winter to Chile, Peru, Panama, and the West Indies. I found a new oestrus larva in the sheep's brain in Chile, I studied the verruga and the uta in Peru, and gathered specimens in the West Indies. Next January I hope to proceed to India to study plague and cholera *in situ*.

I mention all these things not with any intent to magnify my own work, but solely with the desire to make plain to the medical profession what the trust is, and to show that within the restrictions enjoined by the testamentary conditions scientific work of a useful and eminently practical kind is being done.

I am, Sir, yours faithfully,

D. E. ANDERSON, M.D., B.Sc. Lond, M.D. Paris, &c.

THE GOVERNMENT OPHTHALMIC HOSPITAL, MADRAS.

To the Editor of THE LANCET.

SIR,—During the recent meetings of the Oxford Ophthalmological Society, of the British Medical Association, and of the International Congress a number of medical men asked if they might visit Madras for the purpose of seeing the work at the Government Ophthalmic Hospital there. I had at that time every intention of returning to Madras at the end of this year, and I told them that I should be glad to welcome them at my clinic. In the meantime my plans have been changed and I am not returning to India for the present at least. Unfortunately, I have not got the names or addresses of a number of those who thus approached me, and am therefore unable to communicate with them direct. I should be extremely sorry if owing to my inadvertence in not taking the names of all such any inconvenience or disappointment arose to a visitor after so long a journey as that to Madras. I shall therefore be greatly obliged if you will give me this opportunity of letting the matter be known. As a number of those who wished to visit Madras came from India, America, and the continent, I shall be greatly obliged if foreign papers would reproduce this letter. The officer who is acting for me in the Madras Hospital will extend a hearty welcome to any who still care to go there. I can only again express my regret if my own unavoidable change of plans has caused inconvenience to others, and my hope that by giving as early notice as possible I have been able to minimise such inconvenience.

I am, Sir, yours faithfully,

R. H. ELLIOT, Lieut.-Col. I.M.S.,

London, W., Sept. 30th, 1913. Superintendent of the Hospital.

[1] THE LANCET, August 23rd, 1890, p. 391.

MEDICAL ADVISERS.

To the Editor of THE LANCET.

SIR,—The profession should be deeply indebted to Dr. Bertram Rogers, medical adviser to the Insurance Committee, Bristol, for his very interesting letters in the *British Medical Journal* on the subject of "Medical Advisers," also to Dr. Ellwood, referee of the L.N.W. Railway Providence and Insurance Societies.

The important point brought out in their letters is that malingering not only is increasing, but is most likely to further increase unless there be very careful selection of proper men of experience for referees (for if there is a tendency for malingering to increase under the above acknowledged men of experience, how much more so will it increase under less experienced referees).

To attract the proper referee, who must be a man of long experience in dealing with these cases, the terms offered are inadequate, for not many would care to give up their present certainty on such terms.

I am, Sir, yours faithfully,

Harrogate, Sept. 24th, 1913. SHEPHERD BOYD.

THE CASE OF MR. H. T. HAMILTON.

To the Editor of THE LANCET.

SIR,—May I ask your indulgence in placing before the members of the profession a suggestion that help should be offered to Mr. H. T. Hamilton to defray the heavy legal expenses (about £800) which were incurred in his successful defence of the recent action brought against him in the Central Criminal Court for offences against the Lunacy Act? I think that all who followed the evidence and read the remarks of the judge will feel that the action was one that should never have been brought, while the proceedings clearly showed that no medical man is ever safe from malicious or groundless charges. Many people, both lay and medical, have written expressing their sympathy, and in some cases suggesting that a fund should be started, in others expressing the hope that proceedings will be taken against the discredited witnesses. One can scarcely see the Public Prosecutor taking action against those who were practically his own witnesses, and Mr. Hamilton himself is not likely to incur more expense.

The following would be pleased to act on a committee for starting a fund to recoup Mr. Hamilton for his heavy losses: Peter Daniel, F.R.C.S., 1A, Upper Wimpole-street, W.; Mrs. Moran, Mill Hill House, Barnes, S.W.; S. R. Deane, Scothorne Villa, Lincoln; C. N. F. Poole, 5, Huguenot-place, Wandsworth, S.W.; and W. H. Gimblett, 86, Sutherland-avenue, W.

Thanking you in anticipation for publishing this letter,

I am, Sir, yours faithfully,

Sept. 30th, 1913. W. H. GIMBLETT, M.D. Durh.

THE MINUTE BOOKS OF THE HARVEIAN SOCIETY.

To the Editor of THE LANCET.

SIR,—I am endeavouring to trace the past minute books of the above society, some of which are, unfortunately, missing—namely, the council minute books from 1852 to 1878 and the proceedings' minute books from 1873 to 1889. I have already written to a great many of the past officers of the society in the hope of getting information as to the missing volumes, and I should feel much obliged if you will insert this letter in the hope that some past officer or member who may see it may have some knowledge as to the whereabouts of these books. Any communication on the subject had better be addressed to me.—I am, Sir, yours faithfully,

G. DE B. TURTLE,
Secretary.

81, Cambridge-terrace, Hyde Park, W.

CONSUMPTION AND ITS TREATMENT 50 YEARS AGO.

To the Editor of THE LANCET.

SIR,—Looking over a volume of THE LANCET for 1860, p. 413, I was surprised to find that most modern "discoveries" in consumption were then known. THE LANCET quotes Professor Hughes Bennett as having established from researches in the dead-house and in the hospital "the arrest and curability of phthisis, not as an exceptional but as an ordinary result of judicious treatment, or even of the unassisted efforts of nature." The indication of treatment, according to Dr. Hughes Bennett, is "plenty of fresh air, to secure which windows should be open during the night," with good diet. I am, Sir, yours faithfully,

Dublin, Sept. 30th, 1913. J. C. MCWALTER, M.D.

*** See the Harveian Oration on Old and New Views on the Treatment of Consumption, by the late Dr. Theodore Williams, published in THE LANCET, Oct. 21st, 1911.—ED. L.

ORAL PROPHYLAXIS.

To the Editor of THE LANCET.

SIR,—In a letter in THE LANCET of Sept. 27th Mr. P. Furnivall concisely puts the doctrine that "a clean tooth will not decay," and its corollary, "How can we attain that cleanliness?" As he says, the difficulty of cleansing between closely set teeth, and to the bottom of grooves or pits, still more the reaching of the recesses between tooth and gums, with or without tooth powders, is manifestly beyond the power of the ordinary unaided bristle tooth brush, which can at best only scour certain outside convexities and produce an illusive outside polish. His inference that we should supplement it by the use of sterilised water and antiseptic solutions seems to me to be vitiated by the well-known fact that the mouth is not, and cannot be made, a sterile place. It is the normal habitation of various microbes, and must always remain so in the nature of things. How the application of sterile water with antiseptics once, twice, or thrice a day for a few seconds can materially affect a medium in which for the remaining 23 odd hours per diem the natural flora have unlimited powers of growth under a perfect system of incubation passes my comprehension. Given any harmful bacterial growth, it seems inevitable that the bristle brush, as often as it is applied, offers opportunity for inoculation into the gums, especially if they are spongy or diseased. Our real object should be, as Mr. Furnivall clearly sees, the fullest possible removal of food débris, which afford the special nidus for germs. For this purpose I do not think there is any better method than the use of a rubber brush, supplemented by a dental syringe.

The rubber brush, it is true, does not reach the recesses, but it removes surface impurities without the slightest risk to the enamel; and it has the important advantage that it can be applied firmly and vigorously to the gums themselves without the slightest risk of inoculation, and with a powerful effect in *squeezing out* all matter, food or pus, in the recesses between tooth and gum; an excellent and tonic massage effect is also produced, improving the capillary circulation in the gum. After the use of the rubber brush the dental syringe comes in; using simple warm water it can be easily self-applied along all the margins of the teeth, inside and out and between the teeth. A good flush of water thus removes first the food débris, and secondly the pus or other infected fluids already squeezed out by the rubber brush massage.

I regard the morning tooth toilet as being mainly a removal of pus or other germ growths accumulated during the resting period, the evening toilet mainly a removal of food débris, and both to be equally important. At any rate, this simple toilet is highly applicable to the subjects of pyorrhœa and as a preventive of pyorrhœa, and is easily performed by all educated persons, even if its apparatus and correct performance are not suitable for the millions. I am myself unfortunately afflicted with pyorrhœa and have tried vaccinations under a leading expert in this line, but with little avail; and I am perfectly satisfied with my present toilet. The difficulty is that the conservative instinct of dentists makes it almost impossible to have a clean sweep made of one's affected teeth. I had eight out in January, and though all the rest are affected, and will, I am convinced, have to come out, the removal of the worst has been a great benefit to me. Short of extraction—which I believe to be the only thorough and rational cure—the simple toilet described will be found the next best palliative. Having suffered for five years from severe carbuncles, debilitating me and incapacitating me, which I feel convinced were due to undetected pyorrhœa, I would like to put my experience at the disposal of others, which is why I am writing this.

letter] (and have left a third step in the toilet, necessary in severe cases, undescribed).—I am, Sir, yours faithfully,

Sept. 27th, 1913. H. B. L.

THE NATIONAL INSURANCE ACT AND UNREGISTERED DENTISTS.

To the Editor of THE LANCET.

SIR,—Your leading article of Sept. 20th on "Legislation with Regard to Anæsthetics," and the debate upon the report of the British Association's committee, bring into prominence the dangers of the practice of dentistry by unregistered persons. Is it not a "disadvantage of a public kind" that such practice should be permitted at all? Could not the Government, through the Insurance Committees if in no other manner, help in some measure to protect the public? As matters stand at present, it appears medical men must afford medical benefit to those insured persons who may require it in consequence of having been treated by an unqualified person, though such misconduct on the part of the member *may* bring about the suspension of the sickness benefit. *May* is used advisedly, as I understand one society with branches over a great part of the country actually pays such unregistered practitioners out of its friendly side funds. The model rules say an insured person "shall obey the instructions of the practitioner attending him"; but he does not present himself for attendance until the mischief is done. The total of this extra work thrown upon the profession must be very considerable, and borders on "covering" irregular practitioners. It would be a great boon if some line of action were indicated by which this most involuntary aid to unqualified practice could be abolished or largely diminished. I am, Sir, yours faithfully,

Sept. 29th, 1913. M.B.

THE NATIONAL INSURANCE ACT.

Uniformity in Medical Certificates.

REPRESENTATIONS from many quarters have reached the National Health Insurance Commission pointing to the desirability of securing some uniformity of the medical certificates issued in connexion with claims for sickness benefit under the National Insurance Act. The fact will cause no surprise to those who have seen in THE LANCET references to the difficulties which have arisen owing to the demands of various Approved Societies with regard to these certificates being of a contradictory nature. The Commissioners, in Memo. $\frac{173}{\text{I.C.}}$, divide the medical certificates required to be furnished under the Act into the *initial* certificate, which the insured person must forward to the society with his "declaring on note," the *continuing* certificate, and the *final* certificate. A general acceptance has been secured from the Approved Societies of an *initial* certificate, and the form in question, Form Med. 34, has been supplied for issue to all medical men on the panels, who may use it in lieu of Form Med. 26. But concerning the *continuing* and *final* certificates, a common form cannot be found which is adaptable to the administrative requirements of Approved Societies of every type. Forms, however, marked A.S. 75 and 76, have been issued to Approved Societies for their assistance in framing continuing and final certificates to be used in the future.

Funds arising through Insured Persons not having Chosen their Medical Men: the Position in London.

A curious and unexpected situation has arisen in London owing to the London Insurance Committee not having distributed among the medical practitioners whose names are on their lists a large number of insured persons who have failed to make any selection of a practitioner or "panel doctor" to attend them when sick. The obvious result has been the accumulation of a considerable sum of money, which by the end of the year will, it is estimated, amount to £140,000, and this it is contended by some ought to be distributed among the medical men working under the Act. The opinion of counsel has accordingly been sought by the London Insurance Committee, and Mr. Danckwerts, K.C., has advised that the medical practitioners on the panel are only entitled to be paid definite sums calculated at so much per head of the insured persons on their lists. He is unable to find in the contract any right to claim more, and added that the Committee is "not entitled to make presents or distribute largesse among the panel doctors ..... and cannot, as matters stand, deal with the fund." The matter was discussed at a meeting of the London Insurance Committee, when it was urged by medical members of the Committee that the money in question was in their hands for the remuneration of medical men on the panels and should therefore be paid to them. This view will no doubt be shared by medical men in other localities than London where the same circumstances exist, and possibly the advice of further counsel may be invoked. The first question to be decided is what committees have authority under the Insurance Act to do (not what they ought to do ethically) under conditions which, as we understand the matter, need not be universal and might have been avoided. Without wishing to make any unnecessary personal reference, we would add that Mr. Danckwerts is a barrister who enjoys a high reputation in his profession as a lawyer, and that he has expressed his opinion in terms which suggest no kind of doubt or reservation. The question must receive the careful attention of the Commissioners, who will be asked to receive a deputation from the London Committee on the subject. At the same meeting the receipt was reported of Circular 29 I C from the Commissioners recommending a numerical distribution of unallotted persons quarter by quarter "among the doctors on the panel upon whom rested collectively the responsibility of treating the whole of the insured persons." The Commissioners added that adequate arrangements should be made with the doctors on the panel whereby insured persons entitled to medical benefit who were not yet on a doctor's list should be able to receive treatment without delay if required. The Medical Benefit Subcommittee recommended the Committee, before taking action on these lines, to ask the Commissioners to receive a deputation. In the course of debate Mr. F. Briant, chairman of the subcommittee, suggested a friendly action brought by the medical profession against the Committee to settle the point at issue. Dr. H. H. Mills said counsel's opinion struck at the root of the agreement made between the medical profession and the Chancellor of the Exchequer at the beginning of the year. The claim of the medical service under the Act was that all the money ear-marked for medical benefit belonged to the medical service and that service alone, with the exception of the money in respect of those who had made their own arrangements and the money due to the druggists. Mr. H. Kingsley Wood declared that it would shock the public conscience if payment for 400,000 persons went to doctors on the panel who had not done a stroke of work for the money. Dr. B. A. Richmond urged that the doctors on the panel took the risk of sickness amongst these 400,000 people and were entitled to the money. Mr. E. B. Turner said a very definite impression was given when the medical service was inaugurated that all the money would go to doctors on the panel; consequently the Committee was now in a very unfortunate position. Members could not vote the money for fear of being surcharged.

The Question of Complaints in connexion with Insurance Practice.

The Medical Service Subcommittee of the London Insurance Committee since January has had before it 38 complaints made by patients against medical practitioners on the panel, of which 20 were substantiated, and two complaints, both proved, lodged against patients by medical practitioners. The subcommittee has recommended that the practice hitherto pursued shall be continued of only disclosing the name of a medical practitioner complained of when the committee has carried the matter before the Insurance Commissioners with a view to the practitioner being removed from the panel, and when the Commissioners have held the allegations thus made to have been proved. This practice follows the obvious analogies provided by the General Medical Council, the Incorporated Law Society, and the Pharmaceutical Society of Great Britain.

The Amenities of Panel Practice.

"Just because you pay a penny or so a week you imagine that a doctor is to be ordered about like a dog at any moment of the day or night. If the doctor in the most generous way had not put in a plea for you I should have made it a heavy penalty." In these terms Mr. D'Eyncourt, sitting at Clerkenwell police court, admonished a man who, in a

drunken condition, had roused a medical man on whose list of patients the man's wife was included, and sent him at midnight to look for a supposed dying woman who, as a matter of fact, was able to go to work, and who had removed from the address at which she was entered as residing. The defendant was charged with using abusive language, and bound over in the sum of £5 to behave himself for 12 months.

The Cost of Medicine for Insured Patients.

Attention having been drawn at Manchester to the possibility of the Insurance Committee not being able to cover the cost of drugs supplied to patients under the Act through the fund at its command being insufficient, correspondence has taken place in the *Manchester Guardian* which merits attention. The Manchester Pharmaceutical Association Insurance Committee has intimated that it considers that the drug fund, if carefully administered, will meet the demands made upon it under normal conditions if the money be spent on drugs taken at their market value *plus* the cost of preparation. The deficiency, if any, it is suggested, will be due to special brands of drugs being ordered and through payment for "trade marks and proprietary values" being demanded. This, however, does not mean that the prescription of proprietary articles to panel patients is always regarded by Insurance Committees as extravagant, and, indeed, to take up this position would be quite impossible. A few days ago Messrs. E. T. Pearson and Co., Limited, were informed by the London County Insurance Committee that lactagol and the vasogen compounds could be prescribed for panel patients, and that the charges therefor would be passed by the committee, and other Insurance Committees have adopted the same attitude in similar cases.

The Appointment of Medical Referees in London.

The London Insurance Committee have decided to divide London into six districts for the purposes of the appointment of medical referees, instead of four, as originally proposed. The terms of the appointment were fixed at 7*s.* 6*d.* for each examination and report, and reasonable travelling expenses beyond two miles. The Commissioners have only approved these appointments as an experiment for a period ending at Christmas, 1913. The following appointments were made: West District.—Arthur Stanley Woodwark, M.D., B.S. Lond., M.R.C.S. Eng., L.R.C.P. Lond. North District.—John Herbert Burroughs, M.R.C.S. Eng., L.R.C.P. Lond. East District.—John Fletcher Porter, M.B. Lond., L.S.A. South-East District.—Hugh Davies, M.B., B.S. Lond., F.R.C.S. Eng., L.R.C.P. Lond. South District.—Eric Bayley, M.D., B.S. Lond., F.R.C.S. Eng. South-West District.—Reginald Crosse, B.A. Cantab., M.R.C.S. Eng., L.R.C.P. Lond.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the First Professional Examination held on Sept. 23rd, 24th, 25th, and 26th the following candidates were approved in the undermentioned subjects:—

Chemistry and Physics.—Edgar Richard Batho, St. Paul's School; Thomas Cornelius Higgins, St. Bartholomew's Hospital; Samuel Leon Izpigner, London Hospital; Basil Leslie Laver, Guy's Hospital; Amin Mohammed Mishad, King's College; Charles Burton Phillips, Durham College of Medicine; Clifford George Jackson Rayner, St. Bartholomew's Hospital; John Saunders Lewis Roberts, Swansea Technical College; Geoffrey Winter, Birmingham University; and Shebsell Yahilevitz, London Hospital.

Chemistry.—William Blair Spence Andrew, Belfast and Royal Dental Hospital; John Ryther Steer Bowker, Sydney University and Middlesex Hospital; Ahmed Faiq, University College; Noel Edward Fasken, Guy's Hospital; John Hollings, London Hospital; and Frederic Francis Wheeler, St. Mary's Hospital.

Physics.—Herbert Claude Apperly, South-Western Polytechnic; George Wilfred Coombes, London Hospital; Mohammed Ibrahim, Middlesex Hospital; William Percival Nelson, Birmingham University; and Charles Wilson Tomkinson, London Hospital.

Biology.—Ernest Horace Bryant, Guy's Hospital; Ricardo Calvo, St. Thomas's Hospital; John Hollings, London Hospital; Christopher Hugh Macklin, Felsted School; William Percival Nelson, Birmingham University; Mahmoud Ali Tewfick, Charles Wilson Tomkinson, and Hugh Pennefather Warren, London Hospital; Edward Mackay Webster, Guy's Hospital; and Sidney Bertram Winnick and Shebsell Yahilevitz, London Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the Preliminary Science Examination for the Licence in Dental Surgery the following candidates were approved in the undermentioned subjects:—

Chemistry and Physics.—Alice Maud Mary Clegg, Eastern District Secondary School, Douglas; Robert Peter Dewar, London Hospital; Morgan James Evans, Transvaal University, Johannesburg, and Birmingham University; James Ernest Horton, London Hospital; Lionel Beresford James, Bristol University; Ernest Arthur West, Wolverhampton Grammar School; Lindsay William Wilson, London Hospital; and Robert Wolff, Royal Dental Hospital.

Chemistry.—Walter Kember, Liverpool University; Reginald John Newman, London Hospital; William James Robinson, Charing Cross and Royal Dental Hospitals; Percy Williams, Holt School of Science, Birkenhead; and Claude Young, Royal Dental Hospital.

Physics.—George Frederick Harry Bloom, Darlington Technical College; Norman Douglas Green, Eastern District Secondary School, Douglas; Geoffrey Miles Haydon and William Grant Milton, Bristol University; and Frank Watson Stiven, Birkbeck College and Guy's Hospital.

VICTORIA UNIVERSITY OF MANCHESTER.—At examinations held in September the following candidates satisfied the examiners:—

FIRST M.B. EXAMINATION.

Part I., Inorganic Chemistry and Physics.—J. C. T. Fiddes.
Physics.—B. W. Conway, E. R. Gilmore, and R. S. Paterson.
Chemistry.—James Yates.
Part II., Elementary Biology.—James Charnley, J. C. T. Fiddes, T. E. Forshaw, J. B. Higgins, and James Yates.

DIPLOMA IN DENTISTRY.

First Examination.—G. P. Anderson and G. C. Royley.
Chemistry.—E. G. Parkinson.
Second Examination.—Dental Metallurgy.—C. E. Cardwell, Harry Morton, W. S. Roberts, and Herbert Vernon.
Dental Mechanics.—C. E. Cardwell, H. L. Howorth, W. H. D. Quinn, Jessie I. Ramsden, Herbert Vernon, J. V. Wilkinson, and N. H. Wood.

THE CHADWICK LECTURES ON SANITARY SCIENCE.—The syllabus of these lectures, which are delivered free to the public, has just been issued, and during the next four months several series of three lectures will be given at London, Glasgow, Bristol, and Southampton, on Sanitation in Various Aspects. At most of the lectures prominent medical men will preside, including Sir Donald MacAlister, Sir Isambard Owen, Sir William Collins, and Dr. W. P. Herringham. In the first half of October, at Glasgow, Mr. W. E. Riley, superintending architect to the London County Council, will give three lectures on Practical Problems of Housing Reform, and in the last weeks of the month Dr. Leonard Hill at Bristol will take for his subject the Physiological Principles of Heating and Ventilating. During November Sir George Newman, chief medical officer to the Board of Education, and Mr. W. Addington Willis will respectively discuss the Place of the Open-air School in Preventive Medicine and House Drainage Law; while at Southampton Surgeon-General G. J. H. Evatt will take for his subject the History of Physical Efficiency in the Army. In January Dr. Killick Millard will lecture on Vaccination in the Light of Modern Experience. The lectures in London will be held at the University of London, the Institution of Civil Engineers, Westminster, and at Toynbee Hall, Whitechapel. Full particulars can be obtained from the secretary, Mrs. Aubrey Richardson, 8, Dartmouth-street, Westminster.

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE (UNIVERSITY OF LONDON).—After an examination held recently the Entrance Scholarships in Arts and Science have been awarded as follows:—1. Senior Science Scholarships of £75 each: G. K. Bowes, B.A., of Christ Church, Oxford, and R. A. Mansell, B.A., of Emmanuel College, Cambridge. 2. Junior Science Scholarship of £150: J. P. Ross, of Preliminary Science Department, St. Bartholomew's Hospital. 3. Arts Scholarship of £100: J. Dick, of Epsom College, and L. D. Porteous, of Huddersfield College (equal). 4. Jeaffreson Exhibition of £50: R. J. Perkins, of Bedford Modern School.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. J. P. S. Berends, of Nijmegen, one of the oldest members of the profession in Holland, aged 95.—Dr. Franz C. Müller, court councillor of Munich, an eminent neurologist, aged 53. He published numerous works on accidents in connexion with neuroses and on physical therapeutics.—Dr. J. Weise, sanitary councillor of Stettin.—Dr.

P. G. Robinson, formerly professor of medicine in Washington University, St. Louis.—Dr. J. B. Marvin, professor of clinical medicine in the University of Louisville.—Dr. E Fredet, formerly professor of hygiene and therapeutics in the Clermont Medical School.

WE are asked to state that the correspondent who wrote the first of the two anonymous appreciations of the late Dr. Forbes-Ross in our columns last week was Mr. C. R. Haines, of Mazagon, Godalming.

ST. MARY'S HOSPITAL MEDICAL SCHOOL (UNIVERSITY OF LONDON).—The following awards have been made as the result of the competitive examination for Entrance Scholarships:—University Scholarships of 50 guineas each: S. C. Dyke, B.A., Exeter College, Oxford; and W. H. Thomas, University College, Cardiff. Open Scholarships in Natural Science (£75): A. G. Cokkinis, International College, Smyrna; and G. V. Davies, Epsom College, Palmer Scholarship of 25 guineas: G. MacAlevey, Mount St. Mary's College, Chesterfield. Epsom College Scholarship (by nomination): B. Thomas.

ROYAL EYE HOSPITAL.—The opening lecture of the winter term, at which all medical practitioners and students will be welcome, will be given at the hospital, St. George's-circus, Southwark, S.E., on Monday, Oct. 13th, at 4.30 P.M., by Mr. G. A. Berry, President of the Royal College of Surgeons of Edinburgh, the subject being "On the Causes and Symptomatology of Impaired Retinal Activity." On the same day at 8 P.M. a dinner will be held at the Trocadero Restaurant. Former students of the hospital who have not received a notice of this are requested to communicate with the Dean, Mr. A. D. Griffith.

MEDICAL SOCIETY OF LONDON.—A general meeting of this society will be held at 11, Chandos-street, Cavendish-square, W., at 8 P.M., on Monday, Oct. 13th, when the treasurer's report and balance-sheet, as passed by the auditors, for the year ending Sept. 30th, 1913, will be presented, the retiring president and honorary secretary will vacate their respective chairs, and the new officers will commence their duties. The first ordinary meeting of the 1913–14 session will follow at 8.30 P.M., when the incoming President, Sir David Ferrier, will deliver the opening address. Dr. E. Farquhar Buzzard will also read a paper on Varieties of Facial Spasm and their Treatment. The Lettsomian lectures of the society will be delivered on Feb. 2nd and 16th, and March 2nd, 1914, by Dr. F. M. Sandwith, who has selected Dysentery as his subject. The anniversary dinner of the society will take place at the Whitehall Rooms of the Hotel Metropole on Wednesday, March 4th, 1914.

ROYAL SOCIETY OF MEDICINE.—Dr. Hideyo Noguchi, of the Rockefeller Institute, whose recent researches into the pathology of rabies may have such a valuable outcome, will give a demonstration on Monday, Oct. 13th, at 5.30 P.M., at the Royal Society of Medicine, 1, Wimpole-street, London, W. The following is Dr. Noguchi's description of what he will show: (1) Pure cultures of various pathogenic and saprophytic spirochætæ; (2) demonstration of treponema pallidum in the brain in cases of general paralysis; (3) experimental general paralysis in rabbits; and (4) cultural studies of the virus of rabies.—Before the Historical Section, as has already been announced in THE LANCET, Professor Morris Jastrow, the distinguished Assyriologist, of the University of Pennsylvania, will lecture on Friday next, Oct. 10th, on Babylonian medicine.—The Section of Odontology of the Society have issued an important circular relating to grants in aid of scientific dental research. The circular has been sent to all the dental and medical schools in the United Kingdom, the universities, and the research laboratories. It points out that the grants expire on May 1st following the date on which they are made, when a statement of expenditure must be supplied showing that no part of the grant has been applied in payment of personal expenses without permission. The expense of the research having been incurred by a committee of the Section of Odontology, the result becomes the property of the section and cannot be published save in the Transactions of the Royal Society of Medicine without due permission signified in the usual way, while any apparatus purchased with the grant belongs to the society. The circular concludes with the regulations for the report which has to be furnished by the recipient of a grant on April 20th following the allotment. A brief statement of results is required, a list of all instruments purchased, and vouchers as far as possible for all expenditure.

MEDICAL MAYOR.—Dr. Preston King has been chosen mayor for the forthcoming year by the City Council of Bath.

MEDICAL SICKNESS AND ACCIDENT SOCIETY.—The usual monthly meeting of the executive committee of the Medical Sickness, Annuity, and Life Assurance Society was held at 429, Strand, London, W.C., on Sept. 19th, Dr. F. J. Allan being in the chair. Contrary to expectation, the summer months have shown very little falling off in the claims, and the experience has been heavy and slightly over the expectation. New business was well up to the average, and the steady growth of proposals for additional benefits received indicates the satisfaction of members with the society. The half-year balance-sheet considered at this meeting showed that the reserves are now just on £260,000, and each fund shows an increase. The actual amount spent on management for the half year was 5 per cent., and the economy practised in this department has been one of the great factors of the society's success. The society also subscribes largely to the Royal Medical Benevolent Fund and to Epsom College, where it has been instrumental in obtaining many foundation scholarships for the sons of deceased members, and grants of money for their widows. Further information can be obtained from Mr. Bertram Sutton, the secretary of the society, 33, Chancery-lane, London, W.C.

THE RADIUM INSTITUTE.—In THE LANCET of August 5th, 1911, we published an account of the organisation and equipment of the Radium Institute, which was formally opened on August 14th of that year. Our article was illustrated by a number of photographs of the various departments of the building in Riding House-street, and an indication was given of the proposed relationship between the institute and the medical profession on the one hand, and between the institute and the public on the other. It will be remembered that the Radium Institute was founded in 1909 by Sir Ernest Cassel and Viscount Iveagh, whose generosity was turned in this direction at the suggestion of King Edward. Recently certain criticisms of the conduct of the institute have appeared in the lay press. The principal complaint seems to have been that throughout the month of August last the institute was closed, and that during that period the valuable supply of radium which it possesses was lying idle. With reference to these and other criticisms a member of our staff was invited to visit the Radium Institute on Oct. 1st and hear the explanation given by the authorities. Our representative was received by Mr. Hayward Pinch, the medical superintendent, in the absence of Sir Frederick Treves, the chairman of committee, and was given an opportunity of inspecting the work of the institute as it is carried on to-day after two years' occupation of its quarters in Riding House-street. Mr. Pinch explained that the institute was not closed during August as had been alleged, but that that month was chosen for the necessary revarnishing of plates, and consequently new cases were not treated during the time. The laboratory was open throughout the month, and the superintendent or one of his medical assistants was constantly in attendance at the institute, although the nursing staff was given a holiday. It is evident that encouraging results are being obtained from the radium treatment of a number of morbid conditions—notably rodent ulcer and keloid—and that valuable work in various directions is being carried out at the institute; but it seems probable that the benefits conferred by the institution are curtailed by the absence of beds.

LITERARY INTELLIGENCE.—Messrs. Chapman and Hall, Limited, announce the forthcoming publication of "Some Main Issues," by G. Walter Steeves, B.A., M.D., the biographer of Francis Bacon. The book aims to illustrate some of the main issues which influence, directly or indirectly, individual life at the present day. Also a seventh and cheaper edition of the "Surgeon's Log," by J. Johnston Abraham.—Messrs. W. B. Saunders Company announce an illustrated "History of Medicine," by Dr. Fielding H. Garrison, of the Surgeon-General's Office, Washington. The book traces the history of medicine from primitive times, the

story being carried on through Egyptian, oriental, Greek, Byzantine, Mohammedan, and Jewish periods to the mediæval period and the period of the Renaissance, or revival of learning. The history of modern medicine is then related, and the account of each period is followed by a brief survey of its social and cultural phases. Appendices and notes cover the medical chronology, the histories of important diseases, the histories of drugs and therapeutic procedures, and the histories of important surgical operations.—We are informed that Dr. E. G. Younger's book on "Insanity in Everyday Practice," published by Messrs. Baillière, Tindall, and Cox, which has been translated into Chinese, is the first work on the subject ever published in that language. The work of translation has been done by Dr. Maison J. Chu and Dr. Philip B. Cousland, and it has been published by the *China Medical Missionary* of Shanghai. The first edition of this book was quite favourably reviewed in our columns on May 14th, 1904.—The "Physiological Principles of Treatment," by Dr. W. Langdon Brown, published by Messrs. Fratelli Drucker, of Padua, has been ably rendered into Italian by Dr. Corletto Fracesco.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ADAMS, H. F. W., M.B., Ch.B. Edin., has been appointed Surgeon to the Out-patient Department at the Edinburgh Royal Infirmary.

BELL, R. G., M.D. Glasg., F.R.C.S. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Sunderland District of the county of Durham.

BOAD, J. H., M.B., Ch.B. Edin., has been appointed Resident Physician at the Edinburgh Royal Infirmary.

BOLTON, N. HAY, M.B., Ch.B. Edin., has been appointed Resident Surgeon at the Edinburgh Royal Infirmary.

COOMBE, T. S., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Hoo District of the county of Kent.

CRAN, D., M.B., Ch.B. Edin., has been appointed Resident Physician at the Edinburgh Royal Infirmary.

ELLIOTT, G. M., M.B., Ch.B. Edin., has been appointed Resident Physician at the Edinburgh Royal Infirmary.

EVANS, HARRY, M.B., Ch.B. Edin., has been appointed Resident Physician at the Edinburgh Royal Infirmary.

FAIRWEATHER, D. O., M.B., Ch.B. Edin., has been appointed Surgeon to the Out-patient Department at the Edinburgh Royal Infirmary.

GEDGE, A. S., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Pewsey District of the county of Wilts.

HARTLEY, J. N. J., M.B., Ch.B. Edin., has been appointed Resident Surgeon at the Edinburgh Royal Infirmary.

LAIRD, A., M.B., Ch.B. Edin., has been appointed Surgeon to the Out-patient Department at the Edinburgh Royal Infirmary.

LINDSAY, W. S., M.B., Ch.B. Edin., has been appointed Resident Surgeon at the Edinburgh Royal Infirmary.

MCKELVEY, D., M.B., Ch.B. Edin., has been appointed Resident Surgeon at the Edinburgh Royal Infirmary.

MCLEAN, W. F., M.B., Ch.B. Edin., has been appointed Resident Physician at the Edinburgh Royal Infirmary.

MARSHALL, G. G., M.B., Ch.B. Edin., has been appointed Resident Surgeon at the Edinburgh Royal Infirmary.

MORRISON, W. K., M.B., Ch.B. Edin., has been appointed Resident Surgeon at the Edinburgh Royal Infirmary.

OWEN, A. D., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer of Health to the Hampton-on-Thames Urban District Council.

ROBERTSON, R. K., M.B., Ch.B. Edin., has been appointed Resident Surgeon at the Edinburgh Royal Infirmary.

RUTHERFORD, A. A., M.B., Ch.B. Edin., has been appointed Resident House Physician at the Edinburgh Royal Infirmary.

SHEPHERD, W. M., M.B., Ch.B. Edin., has been appointed Resident Physician at the Edinburgh Royal Infirmary.

STEWART, A. M., M.B. Ch.B. Edin., has been appointed Resident Surgeon at the Edinburgh Royal Infirmary.

VON RONN, H. A., M.B., Ch.B. Edin., has been appointed Resident Surgeon at the Edinburgh Royal Infirmary.

WADE, E. W., M.D. Dub., has been appointed Medical Officer and Public Vaccinator for the Mendham District by the Hartismere Board of Guardians.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ALL SAINTS' HOSPITAL FOR OUT-PATIENTS, Buxton-street, E.—Vacancy on Honorary Staff.

ARGYLE AND BUTE ASYLUM, Lochgilphead.—Assistant Medical Officer, unmarried. Salary £175 per annum, with apartments, board, and laundry.

BARNSLEY, BECKETT HOSPITAL AND DISPENSARY.—Senior and Junior House Surgeons, unmarried. Salaries £120 and £100 per annum, with apartments, board, and laundry.

BARROW-IN-FURNESS, NORTH LONSDALE HOSPITAL.—Senior and Junior House Surgeon, unmarried. Salary £120 per annum each, with board, residence, and washing.

BELGRAVE HOSPITAL FOR CHILDREN, Clapham-road, S.W.—Assistant Physician.

BETHLEM HOSPITAL.—Resident House Physician, unmarried, for six months. Salary at rate of £25 per quarter, with apartments, board, and washing.

BIRMINGHAM, QUEEN'S HOSPITAL.—Radiographer. Salary £100 per annum.

BLACKBURN COUNTY BOROUGH EDUCATION COMMITTEE.—Medical Inspector and Assistant to the Medical Officer of Health. Salary £250 per annum.

BOLINGBROKE HOSPITAL, Wandsworth Common, S.W.—Two House Surgeons for six months. Salary £75 per annum, with board, residence, and laundry.

BRADFORD POOR-LAW UNION HOSPITAL AND WORKHOUSE.—Assistant Resident Medical Officer, unmarried. Salary £130 per annum, with rations, apartments, and laundry.

BRISTOL GENERAL HOSPITAL.—First House Physician, Second House Physician, and Casualty House Surgeon, for six months. Salary £80 per annum, with board, residence, &c.

BRISTOL ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN.—House Physician. Salary £80 per annum, with board, rooms, and attendance.

BRISTOL ROYAL INFIRMARY.—Three House Surgeons and One House Physician. Salaries at rate of £100 per annum. Also Throat, Nose, and Ear House Surgeon. Salary at rate of £75 per annum. All with apartments, board, and laundry, and for six months. Also Dental House Surgeon for six months. Salary at rate of £100 per annum, with board, apartments, and laundry.

BURY INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, residence, and washing.

CARDIFF, KING EDWARD VII.'s HOSPITAL.—House Surgeon for six months. Salary at rate of £60 per annum, with board, residence, and laundry.

CHELTENHAM GENERAL HOSPITAL.—House Physician, unmarried. Salary £100 per annum, with board, lodging, and washing.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—Resident Medical Officer. Salary £150 per annum, with board, &c. Also Surgeon.

COLCHESTER, ESSEX COUNTY HOSPITAL.—House Surgeon. Salary £100 per annum, with board, washing, and residence.

CUMBERLAND COUNTY COUNCIL.—Assistant to County Medical Officer of Health. Salary £250 per annum.

DUMFRIES AND GALLOWAY ROYAL INFIRMARY.—Assistant House Surgeon. Salary £65 per annum, with board and washing.

GARTLOCH MENTAL HOSPITAL, Gartcosh, near Glasgow.—Directorship of the Scottish Western Asylums' Research Institute.

GREAT YARMOUTH HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and washing.

HALIFAX ROYAL INFIRMARY.—Third House Surgeon, unmarried. Salary £80 per annum, with residence, board, and washing.

HAMMERSMITH INFIRMARY AND WORKHOUSE, Ducane-road, Wormwood Scrubs, W.—Second Assistant Medical Officer. Salary £130 per annum, with board, lodging, washing, and attendance.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL.—Ophthalmic Surgeon to Out-patients. Also Medical Officer in Charge of X Ray Department. Salary 25 guineas per annum.

HASTINGS, EAST SUSSEX HOSPITAL.—Assistant House Surgeon. Salary at rate of £70 per annum, with residence, board, and washing.

HEMEL HEMPSTEAD, WEST HERTS HOSPITAL.—Resident Medical Officer. Salary £100 per annum, with rooms, board, and washing.

HEREFORD COUNTY AND CITY ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £200 per annum and all found.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—House Physician. Salary for six months 30 guineas.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—Assistant Casualty Medical Officer, unmarried, for six months. Salary £30, with board, residence, &c. Also Medical Registrar. Salary £200 per annum.

HULL ROYAL INFIRMARY.—House Physician, unmarried. Salary £100 per annum, with board and apartments. Also Casualty House Surgeon for six months. Salary at rate of £80 per annum, with board and lodging.

KENSINGTON DISPENSARY AND CHILDREN'S HOSPITAL.—Resident Medical Officer, unmarried. Salary £100 per annum, with board, apartments, laundry, &c.

KETTERING AND DISTRICT GENERAL HOSPITAL.—Resident Medical Officer, unmarried. Salary £100 per annum, with board, residence, &c.

KIMBERLEY, KIMBERLEY HOSPITAL, South Africa.—Bacteriologist and Pathologist. Salary £600 per annum and board.

LEICESTER BOROUGH MENTAL HOSPITAL, Humberstone.—Second Assistant Medical Officer and Pathologist, unmarried. Salary £240 per annum.

LEYTON, WALTHAMSTOW, AND WANSTEAD CHILDREN'S AND GENERAL HOSPITAL.—Resident House Surgeon. Salary at rate of £100 per annum, with rooms, board, and washing.

LIVERPOOL, PARKHILL SANATORIUM.—Resident Medical Superintendent, unmarried. Salary at rate of £400 per annum, with board, residence, and washing.

LONDON COUNTY ASYLUM, Claybury, Woodford Bridge, Essex.—Junior Assistant Medical Officer, unmarried. Salary £170 per annum, with board, apartments, and washing.

LONDON FEVER HOSPITAL, Liverpool-road, Islington, N.—Resident Medical Officer. Salary £250 per annum, with board and residence.

LONDON HOSPITAL, Whitechapel, E.—Surgical Registrar and Medical Registrar. Salary in each case £100 per annum. Also Assistant Anæsthetist.

LONDON MISSIONARY SOCIETY, 16, New Bridge-street, E.C.—Female Medical Missionaries for Central China and South India.

MACCLESFIELD GENERAL INFIRMARY.—Senior House Surgeon and Junior House Surgeon. Salary £100 and £80 per annum respectively, with board and residence.

MANCHESTER WORKHOUSE, Crumpsall.—Junior Resident Assistant Medical Officer, unmarried. Salary £120 per annum, with rations, apartments, washing, attendance, &c. Also Second Assistant Medical Officer, unmarried. Salary £135 per annum, with rations, apartments, washing, attendance, &c.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—House Physician and House Surgeon. Salary at rate of £60 per annum, with board and washing. Also Assistant House Physician and Assistant House Surgeon. Salary at rate of £40 per annum, with board and washing. All for six months. Also Pathologist and Registrar. Salary at rate of £120 per annum. Also Assistant Physician.

MIDDLESBROUGH, NORTH ORMESBY HOSPITAL.—Assistant House Surgeon. Salary at rate of £100 per annum for first six months, and £110 per annum afterwards, with board, apartments, washing, and attendance.

MIDDLESEX HOSPITAL, W.—Dental Surgeon

NEWCASTLE-UPON-TYNE EDUCATION COMMITTEE.—Second Whole-time Assistant Medical Officer. Salary £250 per annum.

NEWCASTLE-UPON-TYNE, HOSPITAL FOR SICK CHILDREN.—Senior Medical Officer and Junior Medical Officer for six months. Salary £100 and £80 per annum respectively, with board, lodging, and laundry.

NEWCASTLE-UPON-TYNE, UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.—Lecturer in Diseases of the Throat, Nose, and Ear, Diseases of the Skin, and Diseases of Children.

NORTHAMPTON COUNTY ASYLUM, Berry Wood, Northamptom.—Junior Assistant Medical Officer. Salary £200 per annum, with board, lodging, and washing.

NOTTINGHAM GENERAL HOSPITAL.—Assistant House Physician. Salary £100 per annum, with board, residence, and laundry.

OXFORD COUNTY ASYLUM, Littlemore, near Oxford.—Assistant Medical Officer. Salary £150 per annum, with apartments, board, and washing.

PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W.—House Physician and House Surgeon for six months. Salary at rate of £52 10s. per annum in each case, with board and residence.

PARK HOSPITAL FOR CHILDREN, Hither Green, London, S.E.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing.

PERTH, JAMES MURRAY'S ROYAL ASYLUM FOR LUNATICS.—Physician-Superintendent. Salary £700 per annum, with furnished house, &c.

PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—House Physician for six months. Salary £75 per annum, with board, residence, and washing.

PORTSMOUTH ROYAL HOSPITAL.—House Surgeon for six months. Salary £80 per annum, with board, &c.

PRESTON, COUNTY ASYLUM, Whittingham.—Assistant Medical Officer, unmarried. Salary £200 per annum, with board, apartments, and washing.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N.—Honorary Assistant Ophthalmic Surgeon. Also Senior House Physician and Senior House Surgeon. Salary £75 each per annum. Junior House Physician, Assistant Pathologist, and Junior House Surgeon. Salary £60 each per annum, with residence, board, and laundry. All for six months.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—Clinical Assistants in Out-patient Department for Medical, Surgical, and Eye cases. Also Assistant Physician.

READING, ROYAL BERKSHIRE HOSPITAL.—House Surgeon and Second House Surgeon for six months. Salary in each case £80 per annum, with apartments, board, and washing.

ROCHDALE INFIRMARY.—Second House Surgeon, unmarried. Salary £100 per annum, with board, residence, and laundry.

ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Male and Female House Physicians and House Surgeons for six months. Board, lodging, and washing provided. Also Female Junior Obstetric Assistant for six months. Board, lodging, and washing provided.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, E.C.—Clinical Assistants in the Out-patient Department.

ROYAL LONDON OPHTHALMIC HOSPITAL, City-road, E.C.—Senior House Surgeon. Salary £100 per annum, with board and residence.

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.—Two Resident House Surgeons, unmarried, for six months. Salary at rate of £100 per annum, with board, residence, and washing.

ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, Plaistow, E.—Junior Resident Medical Officer for seven months. Salary at rate of £70 per annum, with residence, board, and laundry.

SCALEBOR PARK ASYLUM, Burley-in-Wharfedale.—Assistant Medical Officer. Salary £180 per annum, with board, apartments, attendance, &c.

SCARBOROUGH HOSPITAL AND DISPENSARY.—Senior House Surgeon and Junior House Surgeon. Salary £100 and £80 per annum respectively, with board, residence, &c.

SHEFFIELD UNION HOSPITAL, Firvale.—Resident Assistant Medical Officer, unmarried. Salary £120 per annum, with apartments, rations, &c.

SHREWSBURY, SALOP INFIRMARY.—House Physician. Salary at rate of £90 per annum, with board and apartments.

SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—House Physician. Salary at rate of £100 per annum, with rooms, board, and washing.

SWANSEA GENERAL AND EYE HOSPITAL.—House Surgeon. Salary £125 per annum, with board, washing, and attendance.

TAUNTON, SOMERSET AND BATH ASYLUM, Cotford.—Assistant Medical Officer, unmarried. Salary £180 per annum, with apartments, board, washing, attendance, &c.

WAKEFIELD GENERAL HOSPITAL.—Second House Surgeon, unmarried Salary £100 per annum, with board, lodging, and washing.

WARRINGTON, LANCASHIRE COUNTY ASYLUM, Winwick.—Assistant Medical Officer. Salary £200 per annum, with board, apartments, attendance, and washing.

WARRINGTON UNION.—Assistant Resident Medical Officer. Salary £150 per annum, with apartments, rations, &c.

WEST BROMWICH AND DISTRICT HOSPITAL.—Assistant Resident House Surgeon and Anæsthetist, unmarried. Salary £75 per annum, with board, residence, and washing.

WEST HAM AND EASTERN GENERAL HOSPITAL, Stratford, E.—Junior House Surgeon. Salary at rate of £75 per annum.

WESTMINSTER UNION INFIRMARY, Colindale-avenue, Hendon, N.W.—Assistant Medical Officer. Salary £160 per annum, with board, residence, and washing.

WHITEHAVEN AND WEST CUMBERLAND INFIRMARY.—Resident House Surgeon. Salary at rate of £120 per annum, with board and lodging.

WIGAN, ROYAL ALBERT EDWARD INFIRMARY AND DISPENSARY.—Junior House Surgeon. Salary £100 per annum, with rations, apartments, and washing.

WISBECH UNION.—District Medical Officer and Public Vaccinator. Salary £53 per annum.

YORK DISPENSARY AND MATERNITY HOSPITAL.—Resident Medical Officer, unmarried. Salary £140 per annum, with board, lodging, and attendance.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Acts at Clacton-on-Sea, in the county of Essex; at Gillingham, in the county of Dorset; at Shefford, in the county of Bedford; at Willenhall, in the county of Stafford; and at Bungay, in the county of Suffolk.

Births, Marriages, and Deaths.

BIRTHS.

DERRY.—On Sept. 25th, at "Windspoint," Higher Drive, Purley, Surrey, to Dr. and Mrs. D. E. Derry, a daughter.

GRIFFIN.—On Sept. 22nd, at Baldock, Herts, the wife of John P. Griffin, M.R.C.S., L.R.C.P. Lond., of a daughter.

MARRIAGES.

MOLE—HOLMES.—On Sept. 30th, at St. Gabriel's, Warwick-square, S.W., by the Rev. L. H. Nixon, M.A., Precentor of Westminster, and the Rev. Noel Kynaston Gaskell, Curate of St. Gabriel's, Harold F. Mole, F.R.C.S., of 19, Mortimer-road, Clifton, son of the late F. M. Mole, of Westfield-road, Edgbaston, to Harriet (Hettie), youngest daughter of the late Reuben Holmes, of Heanor, Derbyshire.

PEARCE—STIRLING.—On Sept. 27th, at the Church of the Holy Innocents, Fallowfield, Manchester, by the Rev. Eric G. Southam, Percival Leslie Pearce, M.B., Ch.B., second son of the late Mr. and Mrs. William Pearce, of Kingston, Jamaica, to Elizabeth Ferguson, elder daughter of William Stirling, M.D., D.Sc., Belfield Lodge, Fallowfield, Manchester. At Home Nov. 25th and 26th, Enfield House, Bury Old-road, Manchester.

SANDISON—GOLD.—On Sept. 4th, at the South Croydon Congregational Church, Alexander Sandison, M.B., B.C., B.A. Cantab., B.Sc. Lond., of Croydon, to Esther Catharine, eldest daughter of Mr. and Mrs. Gold, of Croydon.

DEATHS.

BROWN.—On Sept. 30th, at Fitzjohn's-avenue, N.W., William Carnegie Brown, M.D., M.R.C.P., aged 54 years.

NORRIS.—On Sept. 29th, at City Walls, Chester, Deputy Surgeon-General Nathaniel Norris (Retired List), in his 83rd year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

BOOKS, ETC., RECEIVED.

LAURIE, T. WERNER, LIMITED, London.

The Cathedrals of Southern Spain. By C. Gasquoine Hartley (Mrs. Walter M. Gallichan). Price 6s. net.

LIPPINCOTT (J. B.) COMPANY, London and Philadelphia.

Syphilis and the Nervous System. For Practitioners, Neurologists and Syphilologists. By Dr. Max Nonne, Chief of the Nervous Department in the General Hospital, Hamburg, Eppendorf. Handbook of Physiology. By W. D. Halliburton, M.D., LL.D., F.R.C.P., F.R.S., Professor of Physiology, King's College, London. Eleventh edition (being the twenty-fourth edition of Kirkes' Physiology). Price 15s. net.

Notes, Short Comments, and Answers to Correspondents.

ZANZIBAR AND PEMBA.

IT is stated in the annual report of the British Vice-Consul (Mr. Beak) that the population of the islands of Zanzibar and Pemba was estimated to be on Dec. 30th, 1911, 197,199, made up of 234 Europeans, 8305 Indians and Cingalese, and 188,660 of other races. Births numbered 1567 in 1910, 1814 in 1911, and 1535 in 1912; the deaths were 3534 in 1910, 3830 in 1911, and 4255 in 1912. In connexion with the apparent excess in the number of deaths over births, it is surmised that, although the registration of births is compulsory by law, the natives constantly evade the regulations. It should also be mentioned that during 1912 an outbreak of cholera accounted for 900 deaths. The outbreak in question lasted from August to December. Possibly the cholera, which was of a virulent type, was introduced from Bombay, where the disease was epidemic in May, 1912. Perhaps the most disturbing feature of the population statistics is the rate of infantile mortality, which for the town of Zanzibar was 288 per 1000 in 1910, 162 per 1000 in 1911, and 193 per 1000 in 1912. A great deal of this loss of child life, which is possibly the gravest question facing any African administration to-day, is due to ignorance and neglect on the part of mothers, and is consequently preventable. An examination of the death returns shows that the diseases which claim the greatest number of victims are tuberculosis (15·9 per cent. of the total), debility (14·0), malaria (13·3), diarrhœa and dysentery (10·2), bronchitis (7·0), dementia (5·4), and anæmia (5·2). During the last few years, although the number of native deaths from malaria has remained practically stationary (the average monthly number of deaths in 1912 was 14·2, as against 15·08, the average for the last six years), and although mosquito-borne diseases are still responsible for 25 per cent. of the total admissions to hospitals, and for 9 per cent. of the total attendances at dispensaries, considerable progress has been made in the sanitation of the town and with the drainage of some swamps and the kerosening of others. Consequently there has been a corresponding improvement in the health of Europeans. During 1912 a severe outbreak of small-pox occurred at Mombasa, but Zanzibar escaped very lightly. This escape may be attributed to the fact that 60,000 of the Zanzibaris had recently been vaccinated.

THE USE OF COLOUR IN BOOKBINDINGS.

To the Editor of THE LANCET.

SIR,—I do not know for certain what are the factors which govern the colour of the binding of any particular scientific work, but would like to suggest that if it is possible a little method should be introduced into the choice. If all works of "medicine" could be bound in blue, all those of "surgery" in red, all those of "chemistry" in green, and so on, the arrangement of books and the discovery of information would be much assisted. If those in authority in the medical profession met the publishing trade on this matter, surely an innovation which would be a benefit to the busy practitioner and to the librarian, and which would prevent the present riot of colour which is observable to anybody with a moderately sized library, would be introduced. Sometimes it is particularly annoying to have two books on diametrically opposite subjects of the same size and shape, and the same colour binding, as the twins will not always keep in their respective departments. I should like to see this classification applied to books on many other subjects—e.g., all French dictionaries of one colour, all German dictionaries of another colour, all Spanish dictionaries of another, and so forth.

I am, Sir, yours faithfully,

London, Sept. 24th, 1913. BOUQUINEUR.

*** The use of colour as a help to systematic arrangement is unduly neglected, but no rules of the sort suggested by our correspondent would be kept by publishers or authors who placed the value of conspicuousness unduly high. What an advertisement for both it would be to be responsible for—say—*the only* mauve biology.—ED. L.

SUGAR AS A PRESERVATIVE OF BUTTER.

AT the Liverpool police-court recently a case was heard in which exporters of butter from Cork were charged upon a summons for selling butter containing cane or beet sugar which had been added to it. Analysis showed that 1·2 per cent. of sugar was present in the sample upon which the prosecution was based, and the evidence of the defendants was to the effect that to preserve butter sufficiently for market purposes 6 or 7 per cent. would have to be used. Salt was present in the sample to the extent of 4 per cent., a usual amount, and the defendants stated that they had used sugar to the extent proved for 35 years, and that other traders did the same. It was also stated that sugar was used in French butter and in Danish. The stipendiary magistrate, after discussion, dismissed the summons on the ground that the presence of the sugar used with salt as a preservative was not an infringement of "the Act of 1887," apparently the Margarine Act, 1887. We have failed to gather from the report before us the precise offence with which the defendants were charged, but we point out that in the case of offences under the Sale of Food and Drugs Acts, by Section 1, Subsection 7, of the Sale of Food and Drugs Act, 1899, "An article of food shall not be deemed to be adulterated by reason only of the addition of any preservative or colouring matter of such a nature and in such quantity as not to render the article injurious to health." We do not see that any evidence was given as to any injury to health likely to result from about 1 per cent. of added sugar in such an article as butter.

THE PSYCHOLOGY OF "DAMN."

IN a recent article in the *Westminster Gazette* discussing the propriety and frequent use of the word "damn" on the stage the writer remarks "there can be no doubt about the fact that swearing in some form gives relief to the feelings and acts in a manner similar to that of a safety valve; it is for the physiologist to tell us why." Explanations are many, but none is simple. The emotion of anger in its varying forms, if at all intense, must find an outlet, and its intensity is often relieved by being first concentrated and then suddenly dissipated through weeping, the use of expletives, or in other ways. When an expletive is used it may range from the mild feminine "bother" to some coarse sexual expression on which the theory of Freud may throw light; it is generally a monosyllable or a dissyllable with the accent on the penultimate and the initial stress strongly pronounced. Just as cramped muscles are relieved by "stretching," so emotion may be relieved by focussing it, so to speak, into a verbal expression the first part of which is uttered with concentrated explosive force. We have heard of a man who, finding the effort of restraint from relieving his feelings before his wife somewhat difficult, discovered with much delight the word "baldaň," which we believe represents the adverb "soon" in a certain artificial language. This innocent word served his purpose equally well with the word "damn," suggesting that it is the sound of the word that is effective rather than the sense. This innocent profaner explained that he was helped by what he called the "sonorous rotundity" of the word, but if the analogy with "stretching" is correct, it is merely an example of the law of action and reaction carried into the field of the emotions, and the line of least resistance is taken to bring about relaxation for the pent-up feelings. The particular word used by individuals is probably the result of imitation, and once a word is found useful for the purpose it becomes automatically and habitually adopted. Of course, there are people whose temperaments are such that they have little or no difficulty, whether by nature or training, in suppressing the emotional feeling, but for the many, perhaps the majority of men and women, some form of expletive, if used decently and in order, may be excused occasionally. But however elaborately we explain the psychology of expletives their use is a confession of weakness—this must be remembered.

MEMORIAL TO A MEDICAL MAN.

AN interesting ceremony took place on Sept. 21st at Bad-Nauheim, when the monument to Dr. Frederick Bode was unveiled and dedicated to the public by the Kurdirecteur, Colonel von Frankenberg. Dr. Bode was one of the first to recognise the qualities of the Nauheim waters, and did much by his writings to bring the place prominently before medical men and the public.

MEDICAL AFFAIRS IN SOMALILAND.

ACCORDING to the annual report prepared by the Acting Commissioner (Mr. G. F. Archer), the estimated population of this British Protectorate comprises 26 Europeans and whites, 305,500 Somalis, 741 Indians, 1857 Arabs, and 789 mixed. The country, owing to its arid nature, is capable of supporting only a sparse nomadic population. The climate is chiefly remarkable for its very dry character. In the interior it is healthy, generally speaking, throughout the year, but the same can scarcely be said of the coast belt. Here, during the "kharif"—i.e., the months of July, August, and not infrequently half September—the atmospheric conditions are very trying for Europeans, and the effect on the nervous system is most pronounced. Terrific gales of dust-laden wind are then prevalent, and the heat is intense, with the thermometer registering 105°—110° F. in the shade at midday, and seldom falling below 100° at night. Most of the sickness, however, occurs during the months immediately preceding and immediately following the "kharif." During the months of November, December, January, and February the climatic conditions on the coast greatly improve.

A general hospital is situated at each of the three principal towns—Berbera, Bulhar, and Zeyla. At Berbara there is accommodation for 42 beds, at Bulhar for 4, and at Zeyla for 6. Camp hospitals, constructed of matting huts erected on wooden frameworks, have been in use at each of the towns for meeting an epidemic of small-pox. These huts have been added to as requirements have demanded; they answer their purpose very well and withstand the wind far

better than the tents used formerly. The number of admissions to the hospitals during the past year was 592 and the deaths 12, exclusive of 787 cases, with 236 deaths, from small-pox treated at the small-pox camps. There is a dispensary attached to each of the hospitals, and the attendances during the year totalled 47,658. A small room is available at the hospital at Berbera for the purpose of blood examinations, urine testing, &c. No culture equipment exists, but microscopic sections can be cut and mounted and simple chemical analyses conducted.

INSANITARY HOUSES IN MARYLEBONE.

Mrs. Potter, of Salisbury-street, Lisson-grove, was ordered to abate a nuisance and pay 2 guineas costs at Marylebone police-court recently in respect of seven houses, known as East Cottages, belonging to her. The evidence of Dr. E. F. W. Bywater, deputy medical officer of health, showed that the houses each contained eight small rooms, and were each occupied by four, five, or six families, four or five persons occupying some of the rooms. Roofs and gutters were defective, rain soaked through into the rooms, the drinking-water was contaminated, the windows were defective, rats abounded, and the backyards were receptacles of sewage matter. The whole condition of the seven houses was declared by Dr. Bywater to be dangerous and injurious to health. It is to be hoped that as a sequel to the order which he has been successful in obtaining the disgraceful state of affairs disclosed may be put an end to.

FREE MEDICAL ADVICE AT KHARKOFF.

IN his report for the past year the British Consul (Mr. Blakey) at Kharkoff observes that there was no epidemic, but that infectious diseases were, as usual, chronic. An improvement is expected in two or three years' time when the drainage of the town is complete. Public hospitals are short of funds, overcrowded, and quite unable to cope with their duties. A slight relief will be given by the new workmen's sick fund law, according to which 12,000 workpeople of the town will be treated at the expense of the employers. The town boasts of a number of competent medical men, and it is very usual for them to give advice free to the poor. Unfortunately many patients who are well able to pay take advantage of this and pay nothing. In Russia it is not etiquette for doctors to make charges or send in accounts except for surgical cases. The fee is regarded theoretically as a free-will recognition of good services. The making up of prescriptions and the preparing of compounded drugs are in the hands of apothecaries, who must be distinguished from chemists, and their prices, though fixed by the administration, are high. Chemists are more numerous than apothecaries. Chemists trade in cosmetics, simple drugs, patent medicines, &c. The sale of patent medicines is largely on the increase, partly because of the greater cost of medicines made by doctors' prescriptions and partly through energetic advertising.

MESSRS. E. MERCK'S ANNUAL REPORT.

WE have received a copy of Merck's annual report which records the principal pharmacological advances for the year 1912. The present issue is the twenty-sixth volume of the series, and, like its predecessors, fully maintains its scientific character as a source of reference on the latest pharmaceutical chemistry and therapeutics. The section on Preparations and Drugs is preceded by an excellent account of the chemistry and pharmacology of lecithin. We understand that a limited number of copies is being sent to members of the medical profession on application to the London Office, 66, Crutched Friars, E.C.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced for 1913:—

April 26th–Nov. 5th (Ghent).—International Exhibition.
May 31st to October (London, Earl's Court).—Imperial Services Exhibition.
May–October (Leipzig).—First International Building Exhibition.
June–October (London, Crystal Palace).—Anglo-German Exhibition.
Oct. 1st–Nov. 1st (London, Shepherd's Bush).—National Gas Exhibition.
„ 28th–Nov. 1st (London, Royal Horticultural Hall).—Twenty-fourth Universal Cookery and Food Exhibition.

In 1914:—

April 14th–18th (New York).—Fourth Congress of the International Surgical Society.
May 1st–Nov. 1st (Lyons).—International Town Life Exhibition.
Aug. 3rd–8th (London).—Sixth International Dental Congress.
„ 10th–15th (St. Petersburg).—Twelfth International Congress of Ophthalmology.
Sept. 7th–12th (Berne).—International Congress for Neurology, Psychiatry, and Psychology.
September (Vienna).—Third International Congress for Diseases of Occupation.
(London).—Anglo-American Exhibition.
(Aberdeen).—Eighty-second Annual Meeting of the British Medical Association.
(Auckland, N.Z.).—Australasian Medical Congress.
(St. Petersburg).—Third Mendeléeff Congress of Pure and Applied Chemistry and Physics.
(Washington, D.C.).—International Congress of Americanists.
(Paris).—Fourth International Medical Congress on Industrial Accidents.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

THURSDAY.

SECTION OF OBSTETRICS AND GYNÆCOLOGY (Hon. Secretaries—T. Watts Eden, C. Hubert Roberts): at 8 P.M.

Opening Remarks by the President, Dr. W. S. A. Griffith.

Specimen:

Dr. Macnaughton-Jones: Pyosalpinx of Accessory Tube.

Short Communication:

Dr. Macnaughton-Jones: Case of Complete Absence of the Internal Genitalia.

Papers:

Dr. Frances Ivens: Report of 26 Cases of Adnexal Tuberculosis.
Dr. Williamson and Dr. Mackenzie Wallis: The Serum Diagnosis of Pregnancy, with a Demonstration of Apparatus and Methods.

FRIDAY.

SECTION OF THE HISTORY OF MEDICINE (Hon. Secretaries—Raymond Crawfurd, D'Arcy Power): at 5 P.M.

Professor Morris Jastrow: Babylonian Medicine.

All Members of the Profession, including Students, whether Fellows of the Society or not, are invited to attend this meeting.

CLINICAL SECTION (Hon. Secretaries—W. Essex Wynter, Thomas H. Kellock): at 8.30 P.M.

Dr. J. D. Rolleston: Case Illustrating Local Treatment of Vincent's Angina by Salvarsan.

And other Cases.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. H. Davis: Clinique (Skin). 5.15 P.M., Lecture:—Dr. F. Langmead: Some Points in the Treatment of Goitre.

TUESDAY.—4 P.M., Dr. E. Pritchard: Clinique (Medical). 5.15 P.M., Lecture:—Mr. F. A. Juler: Squints.

WEDNESDAY.—4 P.M., Mr. H. A. T. Fairbank: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. D. Sommerville: Gastro-intestinal Maladies and Skin Diseases.

THURSDAY.—4 P.M., Dr. E. Wynter: Clinique (Medical). 5.15 P.M., Lecture:—Dr. A. Latham: Malignant Diseases of the Lung.

FRIDAY.—4 P.M., Dr. D. MacKenzie: Clinique (Ear, Nose, and Throat). 5.15 P.M., Lecture:—Dr. H. C. Miller: Clinical Psychology—2. The Scope and Limitations of Psychic Treatment.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. Mr. Pardoe: Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—Out-patient Demonstrations:—10 A.M. Dr. Singer: Medical. Mr. H. Curtis: Surgical. 12 noon, Mr. G. N. Biggs: Throat, Nose, and Ear.—2.15 P.M., Mr. W. Turner: Surgery. 3 P.M., Mr. W. Turner: Operations. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.15 P.M., Mr. R. Lake: Ear and Throat.

TUESDAY.—Out-patient Demonstrations:—10 A.M., Dr. G. Holmes: Medical. Mr. Cole: Surgical. 12 noon, Dr. H. MacCormac: Skin.—2 P.M., Mr. L. McGavin: Operations. 2.15 P.M., Mr. R. Carling: Surgery. 3.15 P.M., Dr. G. Rankin: Medicine.

WEDNESDAY.—Out-patient Demonstrations: 10 A.M., Dr. F. Langmead: Medical. Mr. C. Rowntree: Surgical. 11 A.M., Mr. R. E. Bickerton: Eye.——2 P.M., Mr. L. V. Cargill or Mr. Choyce: Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.15 P.M., Mr. Cargill: Eye Clinique. 4.30 P.M., Mr. C. C. Choyce: Surgery.

THURSDAY.—Out-patient Demonstrations:—10 A.M., Dr. Singer: Medical. Mr. H. Curtis: Surgical. 12 noon, Mr. G. N. Biggs: Throat, Nose, and Ear.——2 P.M., Mr. R. Carling or Mr. W. Turner: Operations. Dr. A. Davies: Pathological Demonstration. 3.15 P.M., Dr. R. Wells: Medicine.

FRIDAY.—Out-patient Demonstrations;—10 A.M., Dr. G. Holmes: Medical. Mr. Cole: Surgical. 12 noon, Dr. H. MacCormac: Skin.——2 P.M., Mr. L. McGavin: Operations. 2.15 P.M., Sir John Rose Bradford; Medicine. 3.15 P.M., Mr. L. McGavin: Surgery.

SATURDAY.—Out-patient Demonstrations: 10 A.M., Dr. F. Langmead: Medical. Mr. C. Rowntree: Surgical. 11 A.M., Mr. R. E. Bickerton: Eye.——10 A.M., Col. Barry: Radiography.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY AND FRIDAY.—3.30 P.M., Clinical Lectures:—Dr. G. Holmes: Regional Diagnosis.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.
THURSDAY.—5.15 P.M., Clinical Lecture.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

TUESDAY.—6 P.M., Dr. W. Griffith: Parasitology of the Skin.
THURSDAY.—6 P.M., Dr. M. Dockrell: Essentials, Clinical and Pathological, to the Diagnosis of Diseases of the Skin.

MANCHESTER ROYAL INFIRMARY (MANCHESTER HOSPITALS POST-GRADUATE CLINICS).

WEDNESDAY.—4.30 P.M., Dr. G. R. Murray: Chronic Infective Endocarditis.

ANCOATS HOSPITAL (MANCHESTER HOSPITALS POST-GRADUATE CLINICS).

THURSDAY.—4.30 P.M., Dr. E. B. Leech: Liver Cirrhosis.

MANCHESTER ROYAL EYE HOSPITAL (MANCHESTER HOSPITALS POST-GRADUATE CLINICS).

FRIDAY.—4.30 P.M., Dr. J. G. Clegg: Subjective Tests for Visual Acuity.

ROTUNDA HOSPITAL POST-GRADUATE COURSES, Dublin.

MONDAY.—10 A.M., Obstetrical Lecture: Eclampsia. 11 A.M., Examination of Patients and Minor Operations.
TUESDAY.—10 A.M., Major Operations.
WEDNESDAY.—10 A.M., Obstetrical Lecture: The Diagnosis of Pregnancy. 11 A.M., Examination of Patients and Minor Operations.
THURSDAY.—10 A.M., Major Operations.
FRIDAY.—10 A.M., Gynæcological Lecture: Gynæcological Diagnosis. 11 A.M., Examination of Patients and Minor Operations.

For further particulars of the above Lectures, &c., see Advertisement Pages.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial Staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1913, which was completed with the issue of June 28th, were given in THE LANCET of July 5th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1913 are now ready. Bound in cloth, gilt lettered, price 16*s.* carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

The following journals, magazines, &c., have been received:—American Post-Graduate, Albany Medical Annals, Archives of Internal Medicine, Bristol Medico-Chirurgical Journal, Indian Medical Gazette, Journal of Tropical Medicine and Hygiene, British Journal of Children's Diseases, Patrician, Revue de Gynécologie, American Journal of Tropical Diseases and Preventive Medicine, Quinzaine Thérapeutique, Journal of Nervous and Mental Disease, Interstate Medical Journal, Journal d'Urologie, Archiv für Experimentelle Pathologie und Pharmakologie, Tropical Diseases Bulletin, Journal of State Medicine, Ophthalmoscope, Review of Neurology and Psychiatry, &c.

Communications, Letters, &c., have been received from—

A.—Ardath Tobacco Co., Lond.; Messrs. Allen and Hanburys, Lond.; Apollinaris Co., Lond.; Dr. Edward von Adelung, Oakland, California; Argyle and Bute Asylum, Lochgilphead, Secretary of; Anglo-American Pharmaceutical Co., Lond.; *The Abolitionist*, Lond.

B.—Messrs. Burroughs, Wellcome, and Co., Lond.; Messrs. Bale, Sons, and Danielsson, Lond.; Bristol General Hospital, Secretary of; Mr. F. E. Beddard, Lond.; Bad Nauheim Municipal Enquiry Office, Lond.; Messrs. Bruce, Green, and Co., Lond.; Messrs. Butterworth and Co., Lond.; Mr. S. L. Bhatia, Cambridge; Messrs. Benger's Food, Manchester; British Oxygen Co., Lond.; Messrs. T. B. Browne, Lond.; *Blackburn Times*, Manager of; Bristol Royal Hospital, Secretary of; Mr. Victor Bonney, Lond.; Mrs. Cloudesley Brereton, Lond.; Messrs. Baillière, Tindall, and Cox, Lond.; Messrs. Boulton and Paul, Norwich; Beckett Hospital, Barnsley, Secretary of; Messrs. A. Burbidge and Co., Lond.; Miss Alice Browne, Lond.

C.—Mr. Harold Collinson, Leeds; Sanitätsrat Dr. Eugen Cohn, Berlin; Mr. Caballero, Lond.; Messrs. J. and A. Churchill, Lond.; Mr. H. Ley Clark, Lond.; Messrs. Constable and Co., Lond.; Clayton Hospital, Wakefield, Hon. Secretary of; Cheltenham General Hospital, Secretary of; Messrs. E. Cook and Co., Lond.; Croydon Mental Hospital, Upper Warlingham, Clerk to the; Canterbury Mental Hospital, Secretary of.

D.—Mr. A. J. D'Souza, Lond.; Professor Delépine, Manchester; Mr. Edward D. Davis, Lond.; Mr. R. Dunstan, Paignton.

E.—Dr. A. M. Elliot, Lond.; Lieutenant-Colonel R. H. Elliot, I.M.S., Lond.

F.—Messrs. Ferris and Co., Bristol; Dr. W. H. Fitzgerald, Hartford, Conn.; Messrs. Fairchild Bros. and Foster, Lond.; *Farm and Home*, Lond., Editor of; Mr. T. R. Freeman, Monkton Combe; Dr. J. B. Farmer, Gerrard's Cross.

G.—Mr. Cecil Graham, Lond.; General Medical Council, Lond., Registrar of; Goodwyn Institute, Memphis, Librarian to the; Guardian Assurance Co., Lond.; Mr. H. S. Gettings, Wakefield; Messrs. Gordon and Gotch, Lond.

H.—Mr. C. R. Haines, Godalming; Dr. Æneas Henderson, Southport; Messrs. C. J. Hewlett and Son, Lond.; Harrogate Hydropathic Co., Manager of; Messrs. Hoskins and Sewell, Birmingham; Sir John P. Hewett, Elgin; Mr. W. H. Hey, Manchester; Mr. T. Harling, Blackburn; Mr. C. W. Hutt, Brighton; Mr. John Howell, Cheltenham; Dr. William Hunter, Lond.; H. B. L.; Harveian Society of London, Secretary of; The Hutcharm Co., Victoria, B.C.; Hospital for Sick Children, Newcastle-on-Tyne, Secretary of; Hereford County and City Asylum, Burghill, Clerk to the; Miss E. M. Homersham, Lond.; Mr. Charles T. W. Hirsch, Woolwich.

I.—International Plasmon, Ltd., Lond.; *Indian Medical Record*, Calcutta.

J.—Miss E. M. Johnstone, Virginia Water; Mr. H. W. Jackson, Lond.; Prof. Morris Jastrow, Philadelphia.

K.—Messrs. H. S. King and Co., Lond.; Miss M. Kordik, Lond.; Messrs. Kutnow and Co., Lond.; Mrs. Kinnings, Fareham; Kensington Dispensary, Lond., Secretary of.

L.—Mr. J. E. Lane, Lond.; Dr. C. Lillingston, Gorleston-on-Sea; Leicester Guardians, Clerk to the; London Press Exchange, Secretary of; Leicester Borough Mental Hospital, Humberstone, Medical Superintendent of; Dr. P. W. Latham, Dalbeattie; Captain R. B. Lloyd, I.M.S., Calcutta; Mr. H. K. Lewis, Lond.; Messrs. Leach and Son, Wisbech; Life-Saving Devices Co., Chicago; *L'Hygiène*, Paris, Editor of; Surgeon-General Sir Charles Pardey Lukis, K.C.S.I., Lond.; Messrs. Longmans, Green and Co., Lond.; Lancashire County Asylum, Winwick, Superintendent of; Messrs. Lee and Martin, Birmingham; L. F. L.; Leeds School of Medicine, Dean of.

M.—Maltine Manufacturing Co., Lond.; Mrs. Y. Maxwell, Hove; Messrs. C. Mitchell and Co., Lond.; Mr. A. E. Melville, Lond.; Medical Sickness and Accident Society, Lond., Medical Secretary of; Dr. S. K. Mullick, Calcutta; Captain Louis H. L. Mackenzie, I.M.S., Dera - Is nail - Khan; Dr. J. C. McWalter, Dublin; Mr. E. Merck, Darmstadt; Dr. William Macdonald, Liverpool; Dr. H. D. McCulloch, Lond.; Mr. J. Y. W. MacAlister, Lond.; The Morgan Reeve Co., Lond.; Messrs. Macmillan and Co., Lond.; Dr. John D. Malcolm, Lond.; Dr. R. W. Murray, Liverpool; Mr. J. Murray, Lond.; Manchester School for Mothers, Secretary of; Medical Agency, Lond.; Mr. R. More, Glasgow; Dr. John L. Martin, Chelmsford; Manchester Royal Infirmary, Secretary of; Mr. P. Michelli, Lond.; Dr. S. G. Moore, Huddersfield.

N.—Mr. H. Needes, Lond.; National Anti-Vaccination League, Lond., Secretary of; National Hospital for the Paralysed and Epileptic, Lond., Dean of; North Staffordshire Infirmary, Hartshill, Secretary of; North Ormsby Hospital, Middlesbrough, Secretary of; New Pegamoid, Ltd., Lond.; Dr. Reginald Nitch - Smith, Lond.

O.—Messrs. C. Oppel and Co., Lond.; Olympic Games, Lond., Special Committee of, Secretary of; Sir William Osler, Bart., Oxford; Mr. Sam Osborn, Victoria Falls; Messrs. Oliver and Boyd, Edinburgh; Oxford County Asylum, Littlemore, Secretary of.

P.—Mr. P. Phillips, Mumbles; Dr. E. H. A. Pask, Eccles; Mr. H. E. D. Pearce, Manchester; Dr. L. Phillips, Lond.; Dr. Charles Porter, Johannesburg; Mr. Peter Paterson, Glasgow; *The Pharmaceutical Journal*, Lond., Editor of; Messrs. G. Pulman and Sons, Lond.

Q.—Queen's Hospital, Birmingham, Secretary of.

R.—Royal Institute of Oil Painters, Lond., President and Council of; Royal Dental Hospital of London, Medical Staff and Lecturers of; Royal Society of Medicine, Section of Odontology, Lond., Dean of; The J. D. Riedel Co., Lond.; Mr. A. T. Roworth, Black Rock; Captain T. C. Rutherfoord, I.M.S., Great Missenden; Royal Society of Medicine, Lond., Secretary of; Royal United Hospital, Bath, Secretary of; Mrs. Aubrey Richardson, Lond.; Dr. W. Robertson, Durham; Mr. J. Rampton, Ascot; Messrs. Rosenberg and Sellier, Turin; Rotherham Hospital and Dispensary, Secretary of; Royal Halifax Infirmary, Secretary of; Royal Portsmouth Hospital, Secretary of; Rothamsted Experimental Station, Harpenden, Director of.

S.—St. Andrew's Hospital, Northampton, Clerk to the; Messrs. W. H. Smith and Son, Lond.; Messrs. G. Street and Co., Lond.; Sheffield Guardians, Clerk to the; St. Mary's Hospital Medical School, Lond., Secretary of; Mr. Julius Springer, Berlin; Dr. G. de Swietochowski, Lond.; Dr. P. S. Chandra Sekar, Madras; St. Bartholomew's Hospital and College, Lond., Medical Officers and Lecturers of; Messrs. W. B. Saunders Co., Lond.; St. Bartholomew's Hospital Medical School, Dean of; Messrs. Simpkins, Marshall, Hamilton, Kent, and Co., Lond.; Messrs. Spottiswoode, Dixon, and Hunting, Lond.; Messrs. Selfridge and Co., Lond.; Dr. T. H. Suffern, Badagry, West Africa; Scarborough Hospital, Secretary of; Smith's Advertising Agency, Lond.; Salford Royal Hospital, Secretary of; Messrs. R. Sumner and Co., Liverpool; Colonel B. Skinner, M.V.O., Lond.; Sheffield Union, Clerk to the; Dr. William Spettigue, Wellington; *Shrewsbury Chronicle*, Manager of; Dr. G. Shuttleworth, Lond.

T.—Mr. J. Thin, Edinburgh; Mr. E. D. Telford, Manchester; Dr. John Tatham, Old Oxtead; Taunton and Somerset Hospital, Secretary of; Dr. S. Duke Turner, Purley; Mr. J. W. Thomson, Wakefield; Dr. Gerald C. Taylor, Reading.

V.—Mr. F. C. W. Vogel, Leipzig; Victoria University of Manchester, Dean of; Messrs. J. W. Vickers and Co., Lond.

W.—Messrs. J. Williams and Son, Bradford; Mr. H. Welter, Paris; Warrington Infirmary and Dispensary, Secretary of; Major F. Winslow, R.A.M.C., Sheffield; Whitehaven and Cumberland Infirmary, Secretary of; Mr. W. Holt White, Lond.; Dr. S. A. K. Wilson, Lond.; Dr. A. S. Worton, Lond.; West London Medico-Chirurgical Society, Hon. Secretaries of; Dr. K. S. Wise, Georgetown; Dr. E. W. Wood-Mason, Leamington; Miss W.; Messrs. J. Walker and Co., Warrington; Waldorf Bindery Co., St. Paul, U.S.A.; Messrs. A. J. Wilson and Co., Lond.; Mr. R. W. Willcocks, Lond.; Dr. Charles J. Whitby, Bath; W. E. G.; Westinghouse Cooper Hewitt Co., Lond., Manager of; Dr. Helen Wilson, Sheffield.

Y.—Dr. E. G. Younger, Lond.

Z.—Messrs. C. Zimmermann and Co., Lond.

Letters, each with enclosure, are also acknowledged from—

A.—Mr. H. B. Angus, Newcastle-on-Tyne; Mr. E. Arnold, Lond.; Mr. G. R. Anderson, Southport; Ayr County Hospital, Secretary of.

B.—Mr. F. H. Bellringer, Windsor; Miss Bristowe, Chalford; Berkshire Education Committee, Reading, Treasurer to the; Dr. W. H. Bishop, Wylam-on-Tyne; Dr. D. Brown, Greenock.

C.—Messrs. J. and A. Carter, Lond.; Captain R. A. Chambers, I.M.S., Bangalore; Mr. J. B. Cooke, Lond.; Messrs. J. W. Cooke and Co., Lond.; Mr. V. Chaplin, Aberystwyth.

D.—Miss Dangerfield, Colwyn Bay; *Daily Mail*, Lond.; Mr. E. Deanesley, Wolverhampton; Dr. A. Downes, Colinsburgh.

E.—Dr. J. Elliott, Chester; E. V.

F.—Fermanagh County Hospital, Enniskillen, Secretary of.

G.—Dr. J. Gilroy, Ecclefechan; Messrs. A. H. Grantham and Co., Reading; Grimsby and District Hospital, Matron of; Glasgow Royal Infirmary, Secretary of; Gartloch Hospital, Gartcosh, Secretary of; Mr. Gant, St. Leonards-on-Sea.

H.—Dr. T. E. Hill, Durham; Messrs. J. Haddon and Co., Lond.; Messrs. J. Heywood, Manchester; Messrs. C. Hearson and Co., Lond.; Mr. C. V. Harris, Buntingford.

I.—Invernith Lodge Retreat, Colinsburgh, Secretary of.

J.—Dr. A. Bassett Jones, Aberystwyth; Dr. R. Jones, Woodford; J. W. C.; Mr. R. Jayaramaswami, Rajahmundry.

K.—Messrs. B. Kühn and Co., Lond.; K. R. S.; Kettering and District General Hospital, Secretary of.

L.—Mr. T. S. Logan, Stone; Lancaster Corporation, Treasurer to the; Liverpool Guardians, Clerk to the.

M.—Staff-Surgeon C. C. Macmillan, R.N., Weymouth; Messrs. J. Menzies and Co., Edinburgh; Margaret-street Hospital for Consumption, Lond., Secretary of; Dr. J. Wallace Milne, Aberdeen; Dr. C. H. Miller, Maidenhead; Mr. A. Mavrogordato, Lond.; Messrs. Mather and Crowther, Lond.; Dr. W. W. Maxwell, Thames Ditton; Dr. R. F. Mackenzie, Karachee; Manchester Guardians, Clerk to the; Dr. P. F. Murphy, Kiltimagh; Mr. R. Matthews, Sheerness; *Midland Counties Herald*, Birmingham, Manager of.

N.—National Dental Hospital, Lond., Secretary of; N., Edinburgh; New Mental Nurses' Co-operation, Lond., Secretary of.

P.—Pahang Consolidated Co., Lond., Secretary of; Dr. C. L. Patton, Springfield, U.S.A.; Mr. B. Pearce, Manchester; Messrs. Pratt and Co., Manchester; P. B.

Q.—Quantock Vale Cider Co., North Petherton; Mr. J. Quirke, Cashel.

R.—Dr. R. R. Ross, Rio Tinto; Reuter's Telegram Co., Lond.; Mr. M. Rink, Lond.; Dr. W. E. Reynolds, Tunbridge Wells; Dr. N. Raw, Liverpool; Royal Liver Friendly Society, Liverpool, Treasurer to the; Royal Eye Hospital, Lond., Dean of; Mr. H. J. Rampling, New Malden.

S.—Mr. F. W. Sears, Lond.; South Devon and East Cornwall Hospital, Plymouth, Secretary of; Saarsbach's News Exchange, Mainz; Mr. B. E. Sansom, Lond.; Scholastic, Clerical, and Medical Association, Lond.; Dr. T. H. Shastid, Superior, U.S.A.; Dr. A. Sandison, Croydon.

T.—Dr. J. P. Tildesley, Willenhall; Dr. A. C. Ta'Bois, South Mimms; Dr. W. Templeton, Doncaster.

V.—Messrs. Van Houten, Lond.; Messrs. G. Van Abbott and Sons, Lond.

W.—Messrs. F. Williams and Co., Lond.; Dr. Walmsley, Edgware.

Hunterian Lecture

ON

FEVER IN PULMONARY TUBERCULOSIS:

ITS SIGNIFICANCE AND THERAPEUTICAL INDICATIONS.

Delivered before the Hunterian Society on Oct. 8th, 1913,

BY FRANK J. WETHERED, M.D. LOND., F.R.C.P. LOND.,

PHYSICIAN TO THE MIDDLESEX HOSPITAL; PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.

IN the first place I have to thank you, Sir, as President, and the council of this society for the honour you have done me in asking me to deliver this lecture. When your secretary, Dr. O. K. Williamson, conveyed your invitation to me, he suggested that I should choose a subject which had a distinctly clinical bearing. I warmly accepted the suggestion, so that I shall only touch very briefly on theoretical considerations, and shall make my observations of as practical a character as possible.

The subject of pulmonary tuberculosis has during the last few years attracted much notice from medical practitioners and laymen. Attention has been mainly concentrated on the afebrile cases, as these naturally yield better results, whatever the form of treatment that may be adopted. Consideration of febrile cases has not been so fully entered into, and I have therefore selected as my subject Fever in Pulmonary Tuberculosis: its Significance and Therapeutical Indications. I shall place a liberal interpretation on the word "fever," taking it to mean any rise of temperature. My endeavour will be to place before you the deductions which may be drawn from a study of the temperature chart from the points of view of diagnosis, prognosis, and treatment.

THE CAUSE OF THE FEVER IN PULMONARY TUBERCULOSIS.

The cause of the fever in this disease has led to much discussion. Fever has been described as a disturbance in the relationship between heat production and heat dissipation, and in pulmonary tuberculosis the balance is very easily disturbed. The tubercle bacilli themselves or their products are thrown into the blood stream, usually resulting in increase in body temperature. Some observers, as Dr. F. M. Pottinger, consider fever to be a result of the protective reaction of the body cells in response to the formation of chemical substances, probably the products of autolysis (albumoses). This question I do not propose to dwell upon this evening.

The occurrence of auto-inoculation, to which I shall refer later, has also given rise to differences of opinion. In certain cases of pulmonary tuberculosis, exertion, physical or mental, but especially the former, is followed by a rise of temperature, often accompanied by other symptoms, such as headache and general malaise. Evidence is forthcoming to show that this is due to a sudden output of bacteria or their products from the disease foci, and uncontrolled bad effects may follow, as after an excessive dose of tuberculin; on the other hand, good results may ensue, corresponding to the administration of an appropriate dose of tuberculin, leading to the conclusion that an auto-inoculation results from the production of a substance similar to tuberculin and possessing similar properties.

The products of organisms other than tubercle bacilli have been supposed to be responsible for the temperature in some cases of pulmonary tuberculosis; in other words, that a secondary or even mixed infection exists. Some observers have maintained that the temperature chart would indicate when such an infection is present, but I do not believe such is the case. Dr. A. C. Inman,[1] superintendent of the Brompton Laboratories, carried out a valuable research for the Local Government Board, and showed that from the temperature chart alone the presence or absence of a secondary infection could not be determined. Moreover, because micro-organisms are found in the sputum in addition to those of tubercle, it does not follow that they play any part in the pathological process that is proceeding. Dr. Inman demonstrated by means of the opsonic index that in many cases, although several varieties of micro-organisms were present, the indices to some of them were normal, thus showing that there was no evidence of infectivity in respect to those particular microbes. The conclusion generally arrived at is that although undoubtedly existing in certain stages of the disease secondary infections have much less effect on the course of the disease than was at one time supposed. Tuberculosis of the lungs is essentially an infection by the tubercle bacillus.

[1] THE LANCET, April 13th, 1912, p. 975, et seq.

THE SIGNIFICANCE OF THE TEMPERATURE CURVE.

I now turn to more clinical details. I would first observe that throughout this lecture, when I speak about temperature, I refer to the mouth temperature, which for clinical purposes I have found perfectly satisfactory. Attempts have been made to classify the temperature curves occurring in pulmonary tuberculosis on a rather too definite basis, but although certain types may be described, yet there is no curve characteristic of the disease. On looking at the temperature chart of a case of typhoid fever, or croupous pneumonia, the nature of the disease can be fairly easily surmised, but such is not the case with tuberculosis of the lungs. Speaking generally, a raised temperature is a sign of activity, provided that it is continuous. It may be continually above the normal, or there may be rises late in the day only, and the higher and more sustained the curve the greater are the active processes going on in the lungs. The reverse, however, does not hold good, and activity may be accompanied by a low or normal temperature; the prognosis in such patients is almost invariably bad; this phenomenon usually indicates a lack of power of response on the part of the body. This low temperature is occasionally seen after a period of fever, and unless this fact be remembered false hopes of improvement may be raised, for the fall may mean that the fatal ending is approaching.

Further, I would like to point out that the temperature is no guide to the stage of the disease, using the word stage in reference to pathological changes. There may be only a comparatively small area of lung affected and very slight physical signs over the lung, yet the temperature is high and shows large daily variations. In some such instances the disease may run a downward course throughout, finally ending in death, the destruction of lung tissue rapidly proceeding. I think such cases are most common in young female subjects from about 18 to 25 years old. On the other hand, extensive lesions may be present in the lungs, cavity formation being well marked, yet the temperature be of a favourable type. In these cases excessive auto-inoculation is not proceeding, although the disease is advanced from a pathological point of view. The immediate prognosis is by no means necessarily bad, and many patients show marked improvement under treatment, and are even able to return to work. These cases demonstrate in a marked manner that in order to form a definite and accurate opinion of a case it is absolutely necessary to study and observe every aspect of the case over some period of time; symptoms, temperature chart, and physical signs must all be considered together and in relation to each other, for to base a diagnosis or prognosis on one aspect only will assuredly lead to error.

Types of Curve in Acute Cases.

There are two types of fever indicative of acute disease which are common, and to which I should like to draw your attention. Before describing these I would first remind you of the variations which occur in the temperature chart of healthy individuals; 98·4° F. is accepted as the normal, but, needless to say, this point does not prevail during the whole 24 hours. There is a daily variation of from a degree to a degree and a half, being lowest in the early morning, and generally highest in the afternoon. It is the amount of variation in the temperature chart of a patient suffering from pulmonary tuberculosis to which I wish to draw your attention; and the observation of this swing yields useful information whatever may be the actual height of the temperature.

In a case of active pulmonary tuberculosis of moderate severity we sometimes find that the temperature is sustained above the normal (Fig. 1); that is to say, the morning temperature is raised as well as that of the afternoon and evening, but the daily variation is not greater than in the

normal curve. Under suitable treatment the fever often subsides, and the disease follows a favourable course. In the majority of these cases the disease is limited in extent, and there is but little softening of the lung tissue. In the second type the temperature is again sustained at a high level, but the daily range is greater than in a normal curve, perhaps two to two and a half degrees of oscillation (Fig. 2). On examination of the patient there will then be found indications that softening and excavation are proceeding. As a rule the larger the extent of lung involved the greater becomes the swing of the temperature; the record may become low in the morning and high later in the day, rising as high as 104° or 105°. Severe clinical symptoms often accompany this type of fever, indicating profound intoxication brought about by the absorption of toxic matters—chilliness, amounting to rigors, aching in the limbs, digestive disturbances, and great weakness. The aspect of the patient is also characteristic—marked flushing of the cheeks and a general lassitude and rapid breathing, which at once attracts attention. The second of these types is the more common, but a combination of the two types occurs more frequently than either alone. Similar to this curve is the one sometimes alleged to indicate the existence of a mixed infection. I have already referred to this subject and stated the reasons for the opinion that no evidence of such an infection can be drawn from the temperature curve.

Other Types of Temperature Chart.

The temperature chart of a slightly active case of pulmonary tuberculosis is very different. (Fig. 3.) The temperature is only slightly raised, and there may be periods in which the curve is almost normal. Nevertheless, at intervals the swing is greater than the normal. In many cases, although the temperature never rises above the normal, yet the daily variation is 2° or more. It will be found that patients with this type of curve often make but slow progress, and great care has to be observed with regard to the daily amount of exercise. This lability and irregularity of the temperature curve is one of the most important early evidences of tuberculosis of the lungs.

There are two other types of curve which are worthy of notice. In the one, the temperature is raised a degree or degree and a half every afternoon or evening (Fig. 4), becoming normal in the morning. In the other a larger swing is noticed (Fig. 5), the rise later in the day being over 100° F., reaching the normal again in the morning. The immediate prognosis in the former is usually fair; in the latter it is not so good, but the second type may gradually assume that of the first, indicating improvement in the patient's condition.

Another interesting type of curve is that of constant variations in temperature following upon increasing exertion. (Fig. 6.) The patient, perhaps, has been kept in bed until the temperature has become normal. Then he is allowed up for a couple of hours and a rise of temperature occurs. This may fall in 24 hours. Another rise is often seen when the patient is allowed up for four hours, again when six hours are permitted, and so on. Further, the excitement and incidental exertion of a visiting day, or the physical examination by the physician may be similarly indicated. In some cases, however, a fall does not take place in 24 hours, and a febrile temperature persists for some time—perhaps as long as three weeks or more—before a favourable curve again appears. A similar rise of temperature may occur after extraction of teeth or some unusual exertion, such as playing the piano. It is striking that the exciting causes are nearly always associated with some form of bodily exertion.

Whilst discussing pulmonary disease associated with high temperature of long duration, I would point out what may lead to diagnostic error—namely, that malignant disease of the lung may be accompanied with fever. (Fig. 7.) During part of the course of malignant disease of the lung the differential diagnosis may be by no means easy. Naturally, if tubercle bacilli are found in the sputum the diagnosis becomes evident. If the cutaneous or other tuberculin test be employed, further confusion may arise if a positive reaction is obtained, for this simply means that the individual has had a tuberculous infection, but it does not prove that the lung trouble is of a tuberculous nature. The true nature of the disease can often not be definitely diagnosed until a late stage, when enlarged glands in the neck or external tumour reveal the real nature of the malady. I need hardly remind you that there are other conditions, such as bronchiectasis, fœtid bronchitis, and so on, all of which may be associated with fever and need careful differential diagnosis from pulmonary tuberculosis.

The inverted type of temperature, the morning point being higher than the evening, is usually to be regarded as of serious import, although the curve need not be high. A case illustrative of this was that of a girl, aged 19, who apparently made good progress in the Brompton Hospital. She gained weight and her temperature was never above 99°, but it was of the inverted type. She was sent to the sanatorium at Frimley, but it was found useless to keep her there, as the slighest amount of exercise caused auto-inoculation which could not be controlled. Her subsequent progress was unsatisfactory.

Precautions necessary to ascertain the True Temperature.

In order that the true temperature occasioned by the disease may be ascertained certain precautions must be observed. Some of these will at once suggest themselves. A little time should be allowed to elapse after a meal, especially if the temperature is to be taken in the mouth. A slight rise is fairly common after a meal, and an interval of at least half an hour should therefore be insisted on. Again, the temperature should never be taken until an hour after exercise. In normal individuals an appreciable rise frequently takes place after exercise, but quickly subsides; the same events will occur in tuberculous cases, provided that excessive auto-inoculation has not taken place; if such has happened the temperature may remain raised for some hours or days. Further precautions are necessary in the case of patients who are able to take baths, whether hot or cold, sufficient time being allowed for the regulation of the subsequent change of temperature. The time of year also may have an influence, especially in debilitated and wasted patients, the temperature being depressed in cold weather and raised in hot. This, of course, particularly applies to mouth temperatures.

Another matter to which I wish to refer is a rise of temperature that sometimes precedes or accompanies the menstrual period. (Fig. 8.) The rise may amount to several degrees. Occasionally cough and other symptoms may become more pronounced during this time. Unless this periodical fever is recognised, a false idea of the temperature curve may be obtained. Especially is this likely to occur when tuberculin is given for diagnostic or therapeutical purposes. If a dose should be given shortly before the period the natural rise may be mistaken for a tuberculin reaction.

Amongst other conditions which may cause temporary rises of temperature in tuberculous subjects, apart from the course of the disease, are the occurrence of an ordinary "cold," probably the result of an infection by one of the catarrhal organisms, and an attack of gout. This affection, however, is rare in patients suffering from tubercle of the lung. The occurrence of hæmoptysis is often followed by fever, and this may be of important prognostic value. If the rise only lasts a few days no undue anxiety need be felt, but if the fever persists it may mean a very serious condition—namely, the rapid spread of the tuberculous process in the form of miliary tuberculosis, which proves rapidly fatal. (Fig. 10.)

THERAPEUTIC INDICATIONS.

Having pointed out some of the conclusions which may be arrived at from a study of the temperature curve in relation to diagnosis and prognosis in cases of pulmonary tuberculosis, I now wish to offer a few remarks as regards the therapeutic indications which may be derived from the same source. When the temperature is high, and especially if it continues for a long period, there is a natural desire to try to artificially reduce it, but whether this is always a wise proceeding is open to doubt. The most favourable temperature for the growth of the tubercle bacillus is about the normal temperature of the body, and it is possible that the existence of fever may to some extent prevent, or at any rate inhibit, the multiplication and activity of the organisms. Moreover, it has also been maintained that phagocytosis is more active, and the other defensive properties of the blood more developed, when a moderate degree of fever is present. Unless, therefore, a high temperature is maintained for some time active attempts to artificially reduce the temperature are not called for. But the prolongation of fever must be a strain

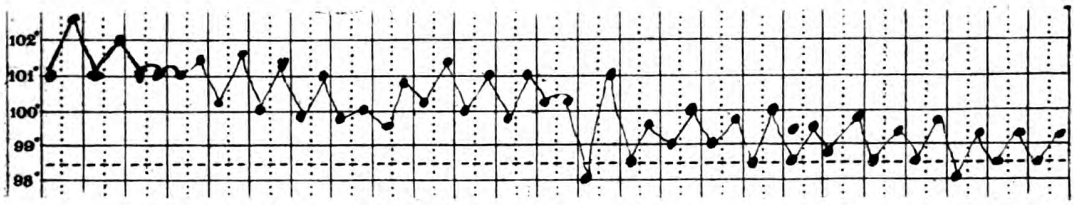

FIG. 1.—Showing sustained temperature with small oscillations. Early lesions at both apices. Patient made good progress.

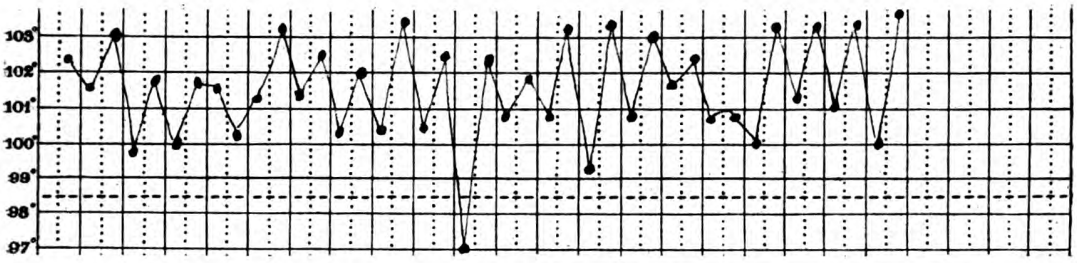

FIG. 2.—Sustained temperature with large oscillations. Active lesions in both lungs. Disease ran an unfavourable course.

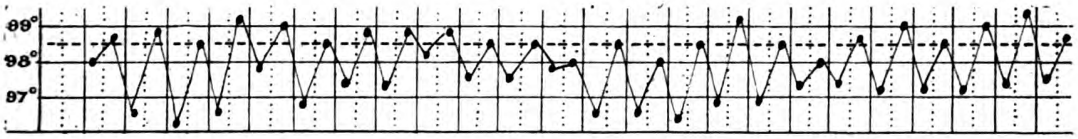

FIG. 3.—Slight activity. Infiltration of both lobes of left lung. No improvement manifested. Patient was not able to take active exercise.

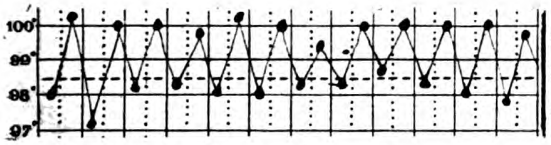

FIG. 4.—Showing slight evening elevation of temperature, falling each morning to normal. Limited infiltration of left lung. Favourable progress of disease.

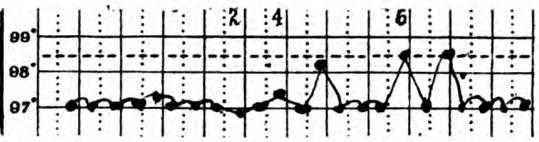

FIG. 6.—Illustrating auto-inoculation. The patient had a limited area of infiltration at the left apex. The figures refer to the number of hours out of bed.

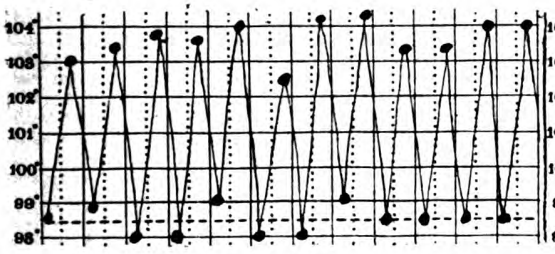

FIG. 5.—High evening elevation of temperature falling each morning to normal. Extensive softening in both lobes of left lung and infiltration of upper lobe of right lung. Unfavourable course of disease.

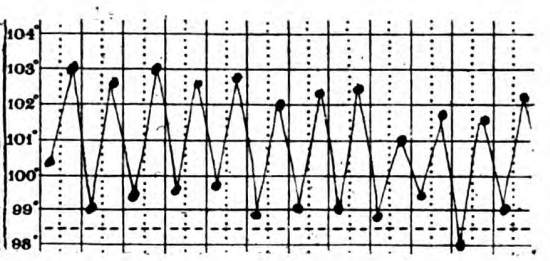

FIG. 7.—Chart of a case of sarcoma of lung.

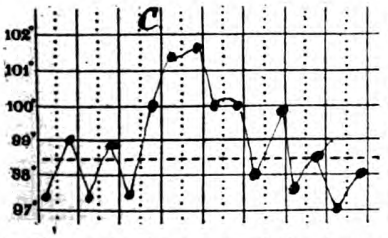

FIG. 8.—Showing rise of temperature during the menstrual period. Menstruation commenced on the day marked C. Patient had advanced lesions in upper lobe of both lungs.

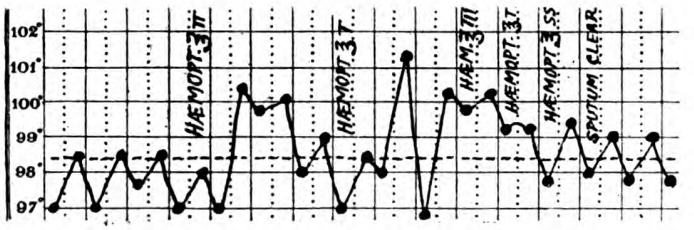

FIG. 9.—Effect of hæmoptysis on temperature. The patient had slight infiltration of the apex of the upper lobe of the right lung.

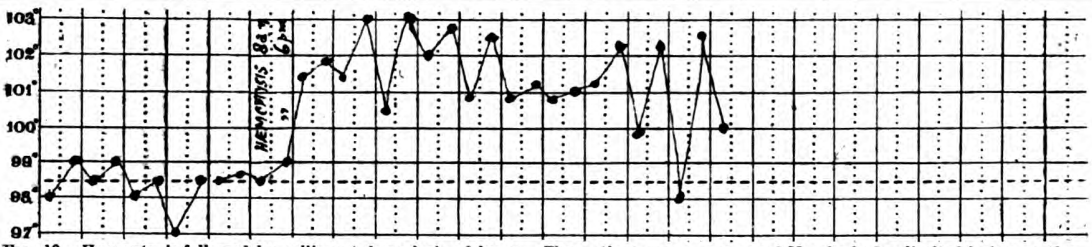

FIG. 10.—Hæmoptysis followed by miliary tuberculosis of lungs. The patient was a man, aged 22, who had a limited lesion at the apex of the upper lobe of the right lung. He was progressing favourably and able to go out into the garden. An attack of hæmoptysis was followed by miliary tuberculosis of the lungs which proved fatal in ten days.

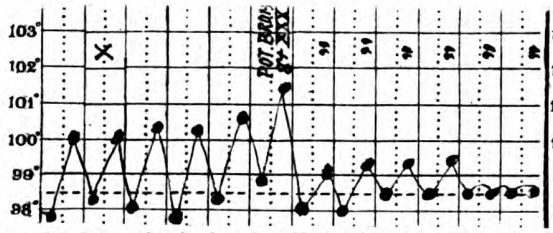

FIG. 11.—Effect of potassium bromide on the temperature in a neurotic patient. There was limited infiltration at the right apex.

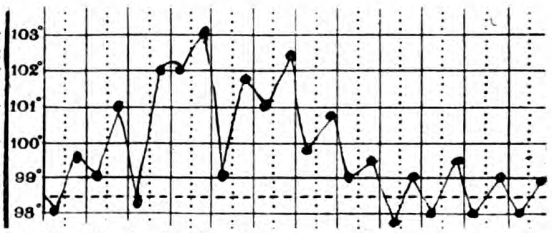

FIG. 12.—Showing the effect on temperature of rest. The patient had excavation in the upper lobe of both lungs.

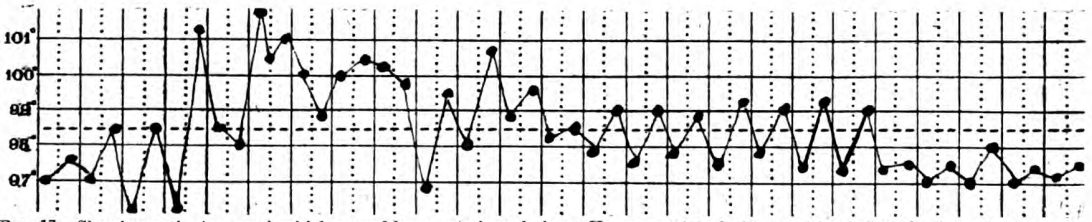

FIG. 13.—Showing patient on work which caused large auto-inoculation. He was sent to bed but not treated on the lines of complete immobilisation. Temperature did not settle for a considerable time. (From Dr. M. Paterson's work on Auto-inoculation in Pulmonary Tuberculosis.)

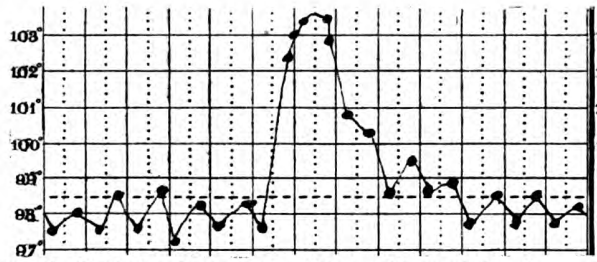

FIG. 14.—Chart of a patient at work which caused large auto-inoculation. He was placed on complete immobilisation and returned to work within ten days. (From Dr. M. Paterson's work.)

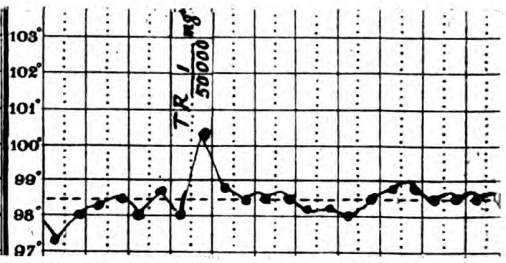

FIG. 15.—Showing febrile response to small doses of tuberculin followed by flattening of the curve. Patient had limited infiltration at right apex.

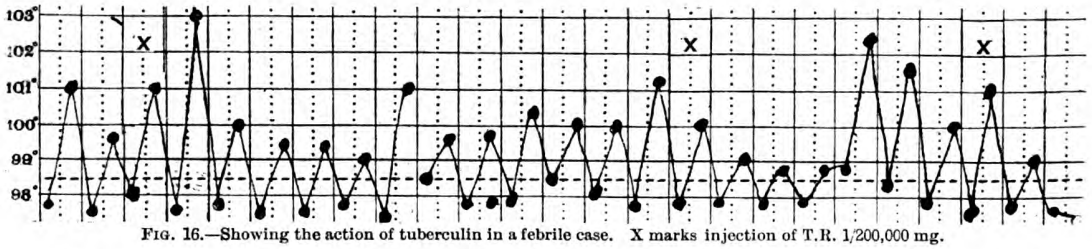

FIG. 16.—Showing the action of tuberculin in a febrile case. X marks injection of T.R. 1/200,000 mg.

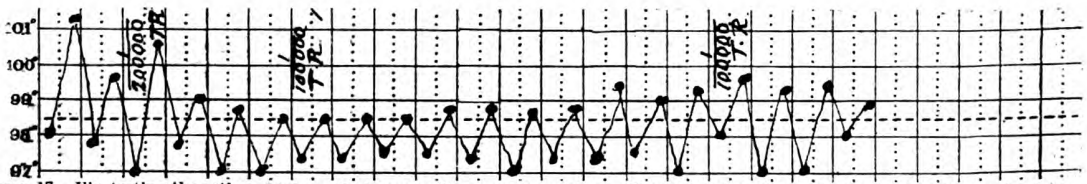

FIG. 17.—Illustrating the action of tuberculin in controlling auto-inoculation. The patient had a limited area of infiltration at the right apex. He was kept at rest until his temperature became normal and then allowed up for two hours and sustained a severe auto-inoculation. The irregular temperature lasted 14 days, the last three days of which are shown. Tuberculin was then given, and after successive doses the temperature became normal. He was ultimately able to be up all day and made good progress.

on the patient's strength, and therefore in some circumstances it may be desirable to try to lower the fever. Many drugs having antipyretic properties have been suggested. In the course of years I have made trial of several, but success has not been great.

The drug to be preferred, according to my experience, is pyramidon; it is claimed to be an amido derivative of antipyrin. The dose is from 5 to 8 grains, but patients tolerate the drug differently and respond to it in a varying manner. In some instances 5 grains given in cachets at night have proved sufficient, whilst in others 5 grains three times a day have been required. As a rule the drug is well borne, and depression has only occasionally occurred. In some cases excessive perspirations were noted. With cryogenin I have had no success. It may be given in doses of 7 to 10 grains in cachets about three hours before the maximum daily temperature is reached. I have not found the smaller doses produce much effect, while the larger ones have been attended by profound depression. Phenacetin and antipyrin I have not given in recent years, although some time ago I tried phenacetin fairly often, but the depression outweighed any advantages the temporary lowering of the temperature might have had. I believe, however, most physicians will agree in the opinion that in the majority of cases antipyretic drugs are not to be recommended. In some patients who are of a strongly neurotic disposition the temperature is very easily affected, and the curve may be irregular, even although the individual is kept at rest as far as possible in bed; under these circumstances the administration of bromides will be found efficacious. (Fig. 11.)

The Value of Rest in Febrile Cases.

A very different agent and far more reliable is rest. The importance of keeping a patient at rest during the active stage of the disease cannot be over-estimated. By this means auto-inoculation may be checked, and thus bacteria and their products are not thrown into the circulation. The period during which rest must be enforced naturally varies with individual cases. Sometimes a short period suffices (Fig. 12), but frequently some weeks or even months may be required. Under the latter circumstances great perseverance is necessary on the part of the patient, but experience shows the reward which follows patience and fortitude. Even apparently hopeless cases after a long period of rest begin to show improvement, but unfortunately, on the other hand, in spite of all care and patience, many cases pursue an unfavourable course from the outset. Rest should be insisted on until, in men, the temperature does not rise above 99° in the 24 hours; in women 99·2°, or even 99·4°, may be allowed. When the curve has maintained this level for four to six days, the patient may be allowed to get up for two hours and sit in a chair, and then the next day he can try moving about his room, the rest of the day being spent on a couch instead of in bed. If the circumstances of the patient permit it, he can be carried into the open air or lie on a couch, properly protected from cold, in front of the window. The time for getting up and the amount of exercise are then gradually extended, careful watch being kept on the temperature chart for any undue rise.

In cases which do not respond to these measures, and in which the patient has been allowed to sit up in bed and perform certain acts for himself, such as washing, writing, and so on, "absolute" rest may be tried. The patient is then treated as though he were suffering from typhoid fever, with the exception, of course, of the diet. He must not be permitted to do anything for himself; he must lie "like a log." He must be fed by the nurse, and must not make any voluntary effort whatsoever. The bed-pan, of course, must be used, and the patient is sponged down and must not wash himself. The visits of friends must be discouraged, and he should talk as little as possible. The beneficial effect of this treatment is especially marked when there has been severe auto-inoculation. Dr. Marcus Paterson, who was for some years medical superintendent at the Brompton Hospital Sanatorium at Frimley, and who elaborated the "graduated labour treatment" for pulmonary tuberculosis, found in the early days of his administration that when a patient exceeded the instructions that were given him, he occasionally received a severe auto inoculation, the effects of which lasted from two to three weeks. These effects were fever (Fig. 13), headache, loss of appetite, and sometimes pain in the side. The temperature was frequently raised for the length of time I have stated and subsequently some little time elapsed before the patient could again engage in the "grade" of labour at which he broke down. If, however, on the appearance of the symptoms the patient was placed on "absolute" rest, the temperature and the other symptoms subsided in a much shorter time (Fig. 14), and he could be speedily restored to the former grade of work. The return to the ordinary movements of everyday life has to be carefully supervised; in fact, as Dr. Paterson has himself expressed it, there must be graduated rest as well as graduated labour.

From my own experience I have not found absolute rest so successful when I have applied it to progressive cases with persistent fever, although I have frequently prescribed it. The fact that uncontrolled auto-inoculations have been occurring continuously and that the pathological process is actively extending explain the difference in the action of this measure in the two classes of cases. The diet during "absolute rest" should be given in as convenient a form as possible, as the patient ought to be fed, but "slop" diet is not necessary. Solid food may still be given unless symptoms of indigestion manifest themselves.

To secure the required rest drugs may sometimes be of assistance. It will be found that patients who have a very severe cough often exhibit a raised temperature. The effort of coughing, especially if prolonged for a considerable time, naturally entails considerable physical exertion, with the result that auto-inoculation follows. If a sedative cough mixture be given, so that the patient is able to obtain actual rest, then a more favourable temperature may be obtained. For the relief of these severe paroxysms of coughing I have found the linctus sedativus of the Brompton Hospital Pharmacopœia as efficacious as any preparation. The composition is: Liquoris morphinæ acetatis, min. viii.; ætheris chlorici, min. iii.; succi limonis, min. xv.; mucilaginem acaciæ ad fl. drm. i. One drachm to be taken when the cough is severe. Codeina or omnopon may also be tried, but I have not found them superior to the morphia preparation. Sponging with tepid water may be tried, but it only gives very temporary relief.

The Administration and Dosage of Tuberculin in Febrile Cases.

When rest and the ordinary drugs fail are there other methods at our disposal? Can tuberculin help us under the circumstances? Some authorities maintain that fever is a direct contraindication to the use of this remedy. I cannot support this view in its entirety. I would rather say that fever is an indication for the most careful administration of tuberculin, but does not absolutely forbid its employment. When treating afebrile cases with tuberculin it is difficult to form any definite criterion as to its effect; we may observe the reactions, but the actual effect on the course of the disease cannot easily be determined. In order to arrive at an absolute conclusion a large number of cases must be dealt with and must be watched for at least five to seven years. Pulmonary tuberculosis is a disease which tends to self-arrest; a large number of patients who are afebrile show improvement under ordinary routine treatment, and it is difficult to prove, because a case of this kind becomes better under the use of a certain remedy, that therefore the improvement is due to the action of that remedy. In judging of the progress of those afebrile cases treated with tuberculin, a further difficulty or source of error is added—namely, failing to distinguish between a tuberculin and a tuberculosis immunity. With febrile cases, however, the circumstances are rather different, for the effect of a remedy is more speedily apparent. For some years I have largely confined myself to the use of tuberculin in febrile cases, and I have met with a certain amount of success, and with the doses I employ I have never found any ill effects follow. When I first used the remedy on patients who had a raised temperature I allowed the patients to remain from three to six weeks in the wards in order to ascertain whether rest and the ordinary methods of treatment would produce good effects. Under the term "ordinary methods" I of course include life as far as possible in the open air or well-ventilated rooms and a good and sufficient dietary. If at the end of that period the temperature curve did not become lower the administration of tuberculin was commenced.

The choice of the particular preparation to be used naturally requires care. Some of the patients had fairly extensive lesions, and it was important, therefore, to employ a tuberculin and in such doses which, whilst exerting an

immunising action, would not produce a focal reaction. Koch's old tuberculin (O.T.) or perlsucht tuberculin (P.T.O.) would not be suitable, as they produce such a reaction; tuberculin residue (T.R.) or bacillary emulsion (B.E.) can bring about an immunising effect when given in small doses without focal reaction. I therefore invariably employ one of the two last named, and have obtained similar results with each, but if I have any predilection it is in favour of B.E.

The dose that should be employed in febrile cases must be extremely small. My usual initial dose is 1/100,000th mg.; sometimes 1/200,000th mg. After a dose is given a few days should be allowed to elapse in order to ascertain whether any result follows. If the temperature chart indicates no change after five to seven days the same dose is repeated. If there is then no change, or if no febrile reaction follows, a dose of 1/50,000th mg. should be administered, and another interval of five days allowed to pass; if there is no change another dose of 1/50,000th mg. is given. The same procedure is repeated with 1/25,000th mg. and 1/20,000th mg. If no lowering of the temperature is achieved by these means, or, in other words, if the same grade and type of fever continue, I think it is better not to proceed with the tuberculin.

If after the initial dose a rise of temperature occurs, the dose should not be increased; in fact, it is advisable to lower it. It is not usual to obtain a febrile reaction with such small doses, but that reactions do occur occasionally under these circumstances is shown by the accompanying chart. (Fig. 15.) If, however, after the initial dose there is a fall of temperature or flattening of the curve, another dose should not be given until the temperature begins to swing again. The interval then required between the doses varies, the principle being not to give another dose until the effect of the former one has passed off; this is shown by the temperature beginning to oscillate. The dose is then increased, and again the variation in the temperature is noted, giving a third and increased dose when are newed swing takes place. With regard to the sequence in the strength of the doses of tuberculin it is better to feel one's way carefully in the febrile cases, treating each patient in regard to the clinical state, the manner in which there is any or no response to the injections, and regulating the doses and intervals between the doses accordingly. At the same time the pulse must be noted, undue frequency necessitating a smaller dose and slower progress. The manner in which tuberculin acts in febrile cases is shown in the accompanying chart. (Fig. 16.) I am strongly in favour of avoiding febrile reactions if possible. The response I prefer to see is a flattening of the curve. (Fig. 15.)

Results of Tuberculin Treatment.

The results I have obtained with the use of tuberculin in febrile cases have varied considerably, but I can say that I have not found these minute doses productive of any harm, and the conclusion I have arrived at is, that when the temperature does not fall after a rest of some weeks under favourable surroundings tuberculin may be administered in the manner I have indicated, and in some instances it will be found efficacious in reducing the fever and in effecting general improvement. To express the matter in other words, the administration of tuberculin occasionally appears to produce an immunising effect sufficiently strong to turn the unfavourable course of the disease into a more favourable one. I am afraid the number of cases in which success is obtained is not large, but nevertheless I do consider that it is a remedy which is well worth giving when other measures have failed, provided that there are no direct contra-indications. If the patient is obviously exhausted by extensive lesions of the lungs, or if there is evidence of rapid disintegration of lung tissues, it is evidently useless to try to obtain an immunising response. The pathological condition is such as to forbid any such treatment. Also, if the type of temperature and physical signs point to miliary tuberculosis (Fig. 10), tuberculin must not be administered.

In some of the cases of pulmonary tuberculosis the effect of the tuberculin is different; it acts as an antipyretic, but has no effect on the course of the disease. The temperature is lowered and a tonic effect is produced, the patient feeling better after each injection, but the progress of the pathological processes is not checked. The length of time that the antipyretic action is continued varies, but it is usually short; nevertheless, it is well to give the remedy on account of the temporary relief which it affords to the patient.

The class of febrile cases in which tuberculin yields the most satisfactory results is that in which the patient is free from fever whilst at rest, but in which a rise of temperature occurs when exercise is taken. This may otherwise be expressed by saying that whilst the patient is at rest no auto-inoculation takes place, but when he gets up and attempts to walk, then auto-inoculation does occur. Tuberculin given in small doses apparently renders him immune to any dose of toxin which he himself can manufacture. I show the chart (Fig. 17) of a case of this nature which well illustrates the beneficial action of tuberculin. By persevering with the treatment a patient, who at first could not be up for two hours without a severe auto-inoculation, is able to be up without fever. Tuberculin has now accomplished its object, and the case may be treated as an afebrile one. The procedure to be adopted is similar to that just described in the case of persistently raised temperature, the initial dose being usually 1/100,000th mg. B.E. The same reduction of temperature sometimes occurs as a result of subjecting the patient to suitable slight movement, such as allowing him to get up for two hours. The explanation of this apparently anomalous phenomenon is the same as applies to the action of tuberculin in febrile cases.

The question of mixed infection has already been discussed, and the idea has naturally been expressed that possibly a vaccine prepared from one or more of the other organisms present might be of value. So far the results obtained have not been altogether encouraging in advanced cases. In less severe and suitably selected cases diminution of fever and in the amount of expectoration appears to have been obtained, with definite relief to the patient.

Conclusions.

From a review of the above considerations it may be assumed that a rise of temperature, apart from accidental factors, may be considered an indication of activity, and that the most reliable means for reducing activity is rest. If, therefore, a patient who has been progressing favourably exhibits a rise of temperature, it must be accepted as a sign that rest must be insisted on. In other words, a patient suffering from pulmonary tuberculosis must live in accordance with his temperature chart. Any increase of cough and expectoration, headache, general malaise, and so on, should always be regarded as calling for a record of the temperature for a few days, and should a rise be found the necessary measures should be taken in accordance with the general features of the case.

In conclusion, I have to offer my sincere thanks to my house physician at the Brompton Hospital, Dr. A. S. Hahn, for the great assistance he has been to me in searching for suitable temperature charts for illustrating my remarks; and, finally, to reiterate that in delivering this lecture my aim has been not to give a scientific disquisition on the factors which produce fever in pulmonary tuberculosis, but to offer some suggestions which I trust may be of value in actual practice.

ROYAL SANITARY INSTITUTE.—The provincial sessional meeting of this institution will be held on Friday and Saturday, Oct. 17th and 18th, at Newcastle-upon-Tyne. On the first day there will be a meeting in the council chamber of the Town-hall at 7.30 P.M., when a discussion will be opened by Professor H. J. Hutchens, D.S.O., bacteriologist to the Newcastle-upon-Tyne corporation, on Some Points in the Relationship of Human to Bovine Tuberculosis; and Dr. S. J. Clegg, assistant medical officer to the borough, and Mr. William Hudspeth will open a discussion on Housing Problems in a Northern Industrial Town. Among those who have promised to take part in the discussion are Sir Thomas Oliver, Dr. T. M. Allison, Dr. H. Renney, and Dr. E. M. Smith. Dr. Philip Boobbyer will preside. On the following day there will be a short demonstration of the new electrolytic treatment of industrial lead-poisoning, a visit to lead works, and a survey of the housing reconstruction scheme at Forth Banks. After luncheon visits will be made to places of local interest. Tickets may be obtained from Dr. H. Kerr, medical officer of health of Newcastle-upon-Tyne, and of the secretary of the Royal Sanitary Institute, 90, Buckingham Palace-road, London, S.W.

An Introductory Address
ON
EXAMINATIONS, EXAMINERS, AND EXAMINEES.

Delivered at the Opening of the Winter Session at St. George's Hospital Medical School on Oct. 1st, 1913,

BY SIR WILLIAM OSLER, BART., M.D., F.R.S.,

REGIUS PROFESSOR OF MEDICINE IN THE UNIVERSITY OF OXFORD.

GENTLEMEN,—In every department of human knowledge men are asking guidance in the solution of a world-old problem—how to train the mind and heart and hands of the young. The past and the present are in the melting pot—the moulds are ready, and all await with eagerness the result of the casting, and none with greater eagerness than our own profession. For we are in a quandary. Naturally conservative, we are bewildered by the rapidity of a forced progress and change. There is a new outlook in every department—not alone in the fundamentals of science and in methods of practice, but in the relations of the profession to the public and to the State. The actual care of the sick, once our sole duty, is now supplemented by such a host of other activities, social, scientific, and administrative, that an ever-increasing number of our members have nothing to do with patients as such. But the chief difficulty is the extraordinary development in every subject of the curriculum—a new anatomy, a new physiology, a new pathology, new methods of practice, to say nothing of phenomenal changes in physics, chemistry, and biology. Everywhere increased complexity and mind-burdening terminology. What is the teacher to do? And more important, What can the poor student do, confronted with so much new knowledge and a Rabelaisian onomatomania? How simple was a cell in the days of Schwann and of Schultze—nucleus, nucleolus, protoplasm, and cell membrane; to-day in one of the very briefest of recent descriptions I counted 40 new names, not one apparently superfluous. Turn to the index of a new treatise in embryology, to a work on immunity, or to a text-book on neurology, and you will appreciate the extraordinary complexity of the diet of the modern student. Even the titles of the journals startle, and to read intelligently an article in the *Zeitschrift für Chemotherapie* or in the new archives dealing with immunity and metabolism requires a special education.

The truth is, we have outrun an educational system framed in simpler days and for simpler conditions. The pressure comes hard enough upon the teacher, but far harder upon the taught, who suffer in a hundred different ways. To help you to realise this pressure and to suggest measures of relief are the objects of this address.

EXAMINATIONS AND THEIR RELATIONS TO EDUCATION.

What a student knows and what he can do—these are judged by examinations, oral, written, and practical. Tests of progress, tests on behalf of the public of fitness to follow certain callings, they have always loomed large in educational systems. At the best means to an end, at the worst the end itself, they may be the best part of an education or the worst—they may be its very essence or its ruin. Helpful if an integral part of the training, they may, and do, prove the intellectual ruin of many good men. Long practice as an examiner—year by year since 1875—in many subjects, in many methods, and in many places, an intimate relation with a large body of students, and a keen interest in medical education give me the assurance, if not of wisdom, at least of experience. Moreover, at the old universities survives a mediæval tradition of the omniscience of the professor, and with my brother Regius of Cambridge I enjoy the rare privilege of examining in every subject in the curriculum, from organic chemistry to obstetrics, a privilege with this advantage—it enables me to see the work of many examiners.

Regarding examinations, I have one question to ask—Are they in touch with our system of education? and one suggestion to make—That from the day he enters the school, in laboratory, class-room, and wards, the work of the student should count, and count largely, in the final estimate of his fitness.

The Influence of Examinations on Medical Education.

Apart from a general feeling of dissatisfaction with the present system, two things strongly suggest a negative answer to the first question. As a discipline of mind and memory examinations play a leading part in all educational schemes. How they may finally control and sterilise the mind of a nation may be read in the story of China. For this has come about, not from lack of brains, not from any failure to appreciate the value of learning, not from any defect in the system itself, which is more rigid and exacting than anything in Western life, but from the blighting influence of an education directed to a single end, the passing of examinations. To test an education by its practical results at the table is to sin against the spirit of the Greeks, who first taught the fundamental lesson that the pursuit of knowledge to be productive must be disinterested. Nothing is more fatal to a true intellectual training than a constant preoccupation with its practical results. To be of any value an education should prepare for life's work. To train the senses for observation and the mind for reasoning, and to acquire a knowledge of the human machine and its disorders, a man spends five or more years at a medical school. Given a knowledge of the sciences on which it is based there is no more fascinating study, since medicine is the only one of the great professions engaging equally head and heart and hand. In its subject matter there is everything in its favour, and it is the easiest possible thing to carry out John Locke's primary canon in education—arouse an interest. With our present methods there is scarcely a subject which cannot be taught easily, and so many of them are practical, manipulative, and not at all difficult to acquire. To an inquisitive mind the study of medicine may become an absorbing passion full of fascinating problems, so many of which present a deep human interest. In the long category of man's conquests none are more brilliant than those with which a teacher of medicine can inspire his class. It is hard indeed to name a dry subject in the curriculum. And yet in an audience of medical students such a statement nowadays raises a smile. Why? Because we make the examination the end of education, not an accessory in its acquisition. The student is given early the impression that he is in the school to pass certain examinations, and I am afraid the society in which he moves grinds this impression into his soul. Ask *at* what he is working, and the student will answer *for* his first M.B. or his final. The atmosphere is Chinese, not Greek, and too often the one aim is to get through. We have become quite shameless about it, and practically admit a failure in our teaching when we advertise special tutorial classes for the different examinations, and consign a large proportion of our pupils to the tender care of "grinders"—and to no purpose! The spirit is taken out of instruction, and teacher and taught alike go down into the valley of Ezekiel—where they stay among the dry bones.

The Number of Rejections.

And a second circumstance proclaims loudly how out of touch are our tests with our teaching. The qualifying examinations of this country are well organised and admirably conducted, and, speaking by the book, I may say that nowhere is the knowledge that a man can use so freely tested in the laboratory and at the bedside. And it has been so for several generations, yet year by year the General Medical Council issues a report that gives any teacher food for serious thought, as it demonstrates, beyond peradventure, how completely out of touch he or the student, or both, has got with the examiner. A medical school is a human factory, turning out doctors as the finished product at the end of five years of careful preparation and fitting of the mental machinery. Failure is incidental to every human effort, and even the Rolls-Royce Company turns out cars from their shops that fail in the tests, but not many. But from our shops, after five long years or even more, we send our medical motors to be tested for the road by the official experts, and nearly one-half are declared to be defective and sent back to the shops. Use and Wont, those "grey sisters," have so dulled the edge of this bitter experience that we have become accustomed to conditions nearly insupportable. Year by year for a generation the returns in the two great final subjects, the most attractive and the easiest to teach, show from 35 to 45 per cent. of rejections.

To the question much thoughtful attention has been given, and in the General Medical Council so far back as 1896

Mr. Pridgin Teale introduced a motion with the following preamble: "That the present system of accumulated examinations and the enormous increase in the number of rejections resulting from it are not only unjust to the student but damaging to medical education." Mr. Teale pleaded wisely and forcibly for a reduction of the examinations and for the substitution in certain subjects of certificates from the teachers and class examinations.

The Council reports show that the percentage of rejections at the final examinations has progressively risen from 12·4 in 1861 to 22·2 in 1876, to 34·8 in 1886, and to 41·9 in 1895. Mr. Teale, who quotes these figures, remarked that with the multiplication of examinations the more fatal do they become. The figures for the five years 1908 to 1912 show a continuation of the upward movement. Take the great final subjects, medicine and surgery, at the three Boards before which we may say the average student presents himself. I will put the collected figures as concisely as possible. The English Board: medicine—passed 1842, rejected 1135, percentage 38·12; surgery—passed 1821, rejected 1506, percentage 45·23. Scotland: medicine—passed 489, rejected 653, percentage 57·18; surgery—passed 492, rejected 731, percentage 59·77. Ireland: medicine—passed 322, rejected 231, percentage 41·77; surgery—passed 326, rejected 239, percentage 42·30. In the five years a total of 4572 students were examined at the Conjoint Boards of the three kingdoms in medicine, of whom 2019 were rejected, a percentage of 44·16. Of 5105 examined in surgery 2475 were rejected, a percentage of 48·48. Take for comparison the three universities—Edinburgh, Oxford, and Cambridge—for the five years ending 1912. At the Scotch capital there were 985 examined in medicine, of whom 267 were rejected, 27·10 per cent.; in surgery 974, of whom 317 were rejected, 31·52 per cent. In Oxford, where the three final subjects are taken together, it is impossible to say upon which subject a man came down, but in the final examination of 135 candidates 47 were rejected, a percentage of 34·81. At Cambridge during the five years, in medicine of a total number 519, 365 passed and 154 were rejected, a percentage of 29·67; and in surgery of a total 603, 233 were rejected, a percentage of 38·64.

There is not so much difference, you notice, between what may be called the pass men of the Conjoint Boards and the men entering the universities, and I do not believe there is any special difference in stringency between the Oxford and Cambridge examinations and those of the London Conjoint Board. There are two other examinations which the élite of the student body affect. How do they stand? All regret that in London only the select and the elect attempt to get the degree of their own University. And it is difficult! Twice in the past five years more students have failed than have passed the final subjects for the M.B. The total figures for the period are: of 1061 candidates examined 481 were rejected, a percentage of 41·01. And, lastly, to one other qualification, greatly prized, sought only by the very best men, the Olympic athletes of their classes, I will refer—the F.R.C.S. Eng. Consider, please, how carefully this group is trained—only the very best venture to compete, and they have a diet of which the intellectual calories are gauged with surpassing accuracy. There is no doubt they are our very best, the picked steeple-chasers of our stables. How do they fare? I am almost ashamed to read the figures. Your ears have tingled already, but only those hardened by familiarity will not be shocked at the demonstration of such a chasm between education and examination. Of 1186 men who have tried for the primary Fellowship examination of the Royal College of Surgeons during the past five years 821 were rejected, 69·45 per cent. Of 680 men at the final Fellowship examination 294 were rejected, 43·23 per cent. The high-water mark of examination futility was reached in May, 1912, when of 118 candidates for the primary Fellowship only 31 were approved. These are picked men, our very best students, the most carefully prepared, who rarely attempt the trial without months of extra study and attendance upon grinding classes. Of the ploughed I have known personally, many seem to have been over-trained, others had spent their time in unprofitable original research; but all, passed and plucked alike, I maintain, are of the highest type of our students, whose calamities proclaim to the world the breakdown of our present educational system.

The failure is general all along the line and in all grades—at the licensing boards, at the older Universities of Oxford and Cambridge, at Dublin and Edinburgh, at South Kensington, and at Lincoln's Inn-fields; with singular uniformity all tell the same tale. There have been uneasiness and talk, but too much self-satisfied indifference, and even after the famous rout for the primary Fellowship in May last year I am told that satisfaction was expressed with the scope and method of the examination! Satisfactory to the examiners, perhaps, though I doubt it; but most unsatisfactory to the teachers, most painful to the students, and by no means a pleasure to the public as represented by the parents.

How May Relief be Obtained?

I venture to offer a few suggestions. First, by simplifying the curriculum to give the students more time. Allow the teachers a free hand in the matter of systematic lectures. Let them be reduced to a minimum or abolished altogether. One advantage they have—subjects may be dealt with which cannot possibly be illustrated in the wards. But such may be better presented in the "seminar" form, the senior students arranging the subjects among themselves under a skilled assistant. London students still have too many lectures in medicine and surgery to attend; Scotch students many more. I do not speak without experience when I say that the subject of medicine, for example, may be taught without the set lecture. The lecture has its value, a precious one from some lips—a Watson's or a Trousseau's; but its day has gone, to give place to other methods better adapted to modern conditions. Think of the saving of time if the lecture list was snipped in half, or if the lecture was limited to a few subjects, such as physiology and pathology, and if it were an offence for a senior student to be seen in a lecture-room!

Then let us boldly acknowledge the futility of attempting to teach all to all students. Burn the anatomical fetish to which we have sacrificed long enough, and to our great detriment. Just glance at "Cunningham's Anatomy"—1465 pages, many in small type, not one of which is without a water-jump for the first Grand National of the medical student. It is barbaric cruelty with so much ahead to burden the mind with minutiæ which have only a Chinese value—a titanic test of memory. To schedule a minimum of the essentials should not be difficult, once the great principle is acknowledged that in all departments of the curriculum only a few subjects can be mastered thoroughly. I am afraid the secret of the tragic tale I have related lies in a quotation which Socrates made to Alcibiades:

> Full many a thing he knew,
> But knew them all badly.

I acknowledge the difficulty of defining in different subjects a minimum of the essential, but it is not insuperable, and such schedules are issued in some universities.

Secondly, relief may be obtained by giving credit for work done throughout the course, changing the present system of "signing up" for one of reports by demonstrators and assistants on the character of the work done by each student. Let all who teach examine. Let education and examination go hand in hand. Let the day's work tell from the moment a student enters the school. Everyone from the junior demonstrator who supervises the student's first dissection to the professor—all should weigh while teaching. Day by day as I see John Smith in the wards, and read his notes, and watch his clinical work and discuss the features of the patients, or as he narrates his case to the class about the bed and he and I have a Socratic dialogue, instruction and examination go hand in hand, and in such a way that at the end the formal tests should be but an amplification, an extension, and an inclusion of the scores of examinations which have been part of the routine of his life. Perhaps at present Utopian, this plan will be feasible in a new and reorganised generation; indeed, it is feasible now in self-contained universities. Once accept the principle that instruction and examination should go hand in hand and the difficulty is solved. The returns are automatically passed on to the head of the department. Yes, but someone will say, "Take the judgment of a group of young teachers? It is absurd!" Not a bit. They see more of the students, come into closer contact, and are better able to judge of the quality of their work than the professor, and much more than any outside examiner. According to the character of his work a student should acquire much or little merit, and

should be able to take to the examination table enough to pass, or at any rate to make the final test in any subject *pro forma*. Where the classes are small, as in many of the provincial universities, this plan could be easily worked. I have had practical experience of it and came to the conclusion early that the judgment of the man who was fit to teach could be taken in estimating the progress of the student's education. And the system is being adopted. A few months ago I went into the beautiful clinical and pathological laboratory of the new Toronto General Hospital, and in one room I found an examination in pathology going on. The candidate had a set of cards in his hands, on each of which were written the details of the post-mortem examination he had made with a careful discussion of the case. Pass or pluck really depended on the cards a man held. He brought his marks with him—instruction and examination had gone hand in hand. I was delighted to hear from Professor MacKenzie that the system, introduced at McGill by my pupil and successor, the late much lamented Wyatt Johnston, had proved very successful in both Canadian schools.

Thirdly, simplify the examinations. Cut off some of the written papers. In the final subjects the long report on cases, the bedside *viva*, supplemented if need be by a special "oral," will give examiners the necessary knowledge of a candidate's mental outlook. If they will consider, not how much he knows, but how he knows what he knows, the long "written" is superfluous. As one watches a man handle a patient it is easy to tell whether or not he has had a proper training, and for this purpose 15 minutes at the bedside are worth three hours at the desk. We must substitute for the quantitative estimate the qualitative, and judge the student as much by manner as by matter.

Fourthly, when possible, evidence of original work should be substituted for examination. Think of the stimulus to British surgery if, in place of the Egyptian tyranny to which our best students now slavishly bow, the President and Council of the Royal College of Surgeons selected for the Fellowship each year the 15 or 20 of the men under 30 who had distinguished themselves most highly in surgical research. It would change the mental attitude of the younger generation, instil the spirit of Hunter into its members, and prevent the paralysing mental sterility that overtakes many good men who now spend precious plastic years in the dry drudgery of examination details.

Fifthly, compel no student to pass an examination twice in the same subject. At present brain and pocket alike suffer, and the burden could be lightened by a free reciprocity between the examining boards.

EXAMINERS AND THEIR DUTIES.

Men are usually very superior to the system in which they work, and so it is with examiners. After what has been said you may be disappointed not to hear a tirade against them; but I have had a singularly happy experience with my fellow inquisitors, whom I have found, as a rule, among "the mildest-mannered men that ever scuttled ships or cut throats." The two extreme types, the metallic and the molluscoid, illustrate inborn defects of character. The aggressive, harsh nature comes out strongly at the table, and the hard face, with its "what-the-devil-do-you-know" expression, sends a chill to the heart of the candidate, and it reaches his bone marrow when the first question relates, perhaps, to a serious mistake in his paper. Imagine the mental state of a poor chap greeted with, "What did you mean by saying that the ciliary muscle is supplied by the pneumogastric nerve?" And the worst of it is that the metallic examiner may have no sense whatever of his failings, but is rather apt to pride himself on a keen appreciation of his duties. I remember a hard-faced inquisitor who took, so it seemed, the greatest pleasure in torturing his victims—dwelling with fiendish glee on all the small mistakes he could find, criticising the spelling, and ending on one occasion with the cheerful remark, "Mr. Jones, who taught you to write?" That evening, talking about examinations, I said in a joking way: "Judge Jeffreys, you are a heartless brute; I wonder some student has not assaulted you." He took it very much to heart, and I had a long letter about the great responsibility of the position and the rigid sense of duty he felt towards the University and the public. And the facial expression of the fellow examiner is not without importance, whether sympathetic, neutral, or antagonistic. One co-examiner always had a sardonic expression, a sort of Arian grin, plainly saying, "Well, you are a hopeless idiot!" The examination room may have the atmosphere of a cold storage chamber, and a student knows at once the type of man with whom he has to deal.

At the other extremity is the invertebrate examiner, so soft and slushy that he has not the heart to reject a man. It is a variety not often met with in this country, but it exists. Sympathy with the student and a strong feeling for his position may completely overmaster the sense of duty to the university and to the public. A former colleague was made unhappy for days if he had to reject a candidate. For some years I sat on an examination board with an elderly professor, a man of great force of character and ability, who never gave a candidate less than 80 per cent. of the possible marks. In the case of the most hopeless duffers with 20, 30, or 40 per cent. in other subjects he would call out "pass." He was a great grief to me, as well as a mystery. At the last meeting which he attended as an examiner he tossed his book to me with a malicious smile. There were 116 candidates, not one of whom he had rejected, and not one of whom had less than 80 per cent.!

Between the metallic and the molluscoid is the large group of sensible examiners who try to put the candidate at his ease and to find out what he knows in a simple, sympathetic manner. But in any case the examiner is apt to take an unfair advantage of his position, and quite unconsciously. A specialist to whom the facts of his subject have become familiar and ingrained is apt to forget the years that have given the facility and the knowledge; and he may wonder when a man hesitates over an Argyll-Robertson pupil or mistakes a pericardial rub for an aortic insufficiency murmur. The most grievous mistake of the examiner is to regard the candidate as his mental equal and to expect from him knowledge of the same quality as that which he possesses, ignoring his long years of study and the short years into which the student has had to cram the knowledge of a dozen subjects.

Examining is often a heart-breaking task, with little to relieve the monotony of the long-drawn papers. It is distressing to meet with abysmal ignorance of elementary facts, and to realise with sorrow how many more minds are constructed as sieves than as sponges. But there are compensations, and who is there among us who does not appreciate Comte's statement that there were few more delightful experiences than the sweet and softened feeling when a young man's examination was thoroughly satisfactory? But it is much nicer to watch the gradual growth of a student's knowledge and to get it out retail day by day than to drag it out wholesale at set times. One thing is certain—the best we have should be devoted to our duties as examiners. Men should give their whole time to the business when at it. Much-engaged men should not be chosen, and to examine in the evening, after a hard day's work, is to handicap the candidates. We shall no doubt come to a time when professional examiners will be appointed by the General Medical Council to act as associates and assessors to the professors. That it is not a task lightly or inadvisedly undertaken the returns I have given indicate only too clearly. Not that we can lay at the doors of the examiners the responsibility for the lamentable state of affairs to which I have referred. No doubt there are unduly severe examinations, and there are examiners with hearts as hard as pieces of the nether millstone, but these are exceptions.

THE EXAMINEE AND HIS POSITION.

When quoting figures I purposely dealt chiefly with the results of the final examinations, and I am sure the feeling uppermost in your minds was one of sympathy with the hundreds of young men who, after five years of hard work, fail in ordinary tests, and this brings us to a brief consideration of the examinee and his position. In two respects he is an unfortunate victim. Of one I have already spoken—the enormous development in the subjects of the curriculum; and here, I am sure, lies his serious difficulty. It is the case of a quart measure and a pint pot. Intellectual dyspepsia from cramming is at the bottom of his trouble. It is like a diet of hot bread, which a man can stand at first, but, as Lowell says in the "Fable for Critics"—

> By gradual steps he
> Is brought to death's door by a mental dyspepsy.

Another cause of the widespread rejections is defective preliminary education; but let me emphasise the fact that

the percentages of rejections are nowhere higher than among the very best students—e.g., Cambridge men, among whom in some subjects more than 50 per cent. are rejected. I do not deny that much could be done to relieve the present stasis if all medical students began thoroughly trained in physics, chemistry, and biology. In this respect matters are improving year by year. And we should be more honest with the feeble ones, not fitted either by breeding or by pasture to pursue their studies, who should be asked early to withdraw. It is infinitely kinder to stop a man in his career than to allow him to struggle on painfully and submit to the humiliation of half a dozen or more rejections.

The conclusion of the matter is, the student needs more time for quiet study, fewer classes, fewer lectures, and, above all, the incubus of examinations should be lifted from his soul. To replace the Chinese by the Greek spirit would enable him to seek knowledge for itself, without a thought of the end, tested and taught day by day, the pupil and teacher working together on the same lines, only one a little ahead of the other. This is the ideal towards which we should move. The pity of it all is that we should have made an intolerable burden of the study of one of the most attractive of the professions, but the reform is in our own hands and should not be far off. A paragraph in an address of the late Dr. Stokes contains the pith of my remarks: "Let us emancipate the student, and give him time and opportunity for the cultivation of his mind, so that in his pupilage he shall not be a puppet in the hands of others, but rather a self-relying and reflecting being."

An Introductory Address

ON THE

PRESENT PROBLEMS RELATING TO THE ORIGIN OF MODERN RACES.

Delivered at the Opening of the Winter Session in Medicine at the University of Birmingham on Oct. 7th, 1913,

BY ARTHUR KEITH, M.D. ABERD., F.R.C.S. ENG.,

CONSERVATOR OF MUSEUM AND HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

GENTLEMEN,—Less than a month ago the Principal of this University took the members of the British Association a long excursion into space and bade them look on the planet on which they live at such a distance that neither man nor beast was within the limits of sight. Only great structures like the Forth Bridge and the Assuan Dam were visible.[1] To-night I want you to look at the earth a little closer—near enough to see its variegated covering of humanity as its continents revolve under our eyes.

THE WORLD'S CARPET OF HUMANITY.

As the western seaboard of Europe passes by and our own country comes in sight we shall suppose we are near enough to perceive that the human carpet along our Western coast is not quite of the same texture as that which covers the lands sloping down to the North Sea. When Europe itself comes under our gaze the pattern of the human carpet begins to change, and by the time the Far East has risen under the morning sun we shall admit, I think, that the change has become decided. A pall of smoke, the wreckage of a battle-field, the demarcation of new frontiers reveal to us one of the processes at work in modifying the pattern of our carpet. When we turn our eyes southwards and view Africa across the Mediterranean there is at first no marked degree of change—not until the great forest region beyond the Sahara comes in sight. A glance from Northern Europe to Central Africa reveals the extremes in the earth's covering of humanity—not the extremes of material—merely of pattern or design; European and African seem to be products of the same loom. In the southern corner of Africa human contrasts of another kind may catch our eye. We may there see a valiant attempt being made to weave a new human carpet, one in which the European thread of the woof will not intertwine with the African thread of the warp. In this new carpet lie the decaying threads of one of the most remarkable patches to be seen in the widespread covering of humanity—the Bushman and Hottentot tribes.

As Europe and Africa sink out of sight and Asia rolls past under us, we see the human pattern again undergo a change. South of the Himalaya the plains of India are covered by peoples of diverse kinds, in whom we seem to detect a mixture of European and African features. North of the Himalaya a wide part of the earth is covered by men who are quite unlike those already seen elsewhere. The Mongolian type cannot be compounded by mixing other known elements of humanity. South of the Equator—the Asiatic aspect of the hemisphere—in Australia and the islands of the Pacific we may perceive a bewildering mixture of human patterns, varying from the negro type towards the European and also towards the Mongolian. Lastly, the new world unfolds itself. At first sight it seems to present an entirely European complexion. Peering beneath the surface, however, it is easy to see numerous remnants of diverse and ancient races. More than in any part of the earth the web of humanity is being actively woven in the New World. North of Mexico there is a resolute determination to keep the white and black threads separate; from Mexico to Cape Horn nature weaves the human web as she will.

THE PERMANENCY OF HUMAN TYPES.

Having thus followed Sir Oliver Lodge into space and surveyed in a cursory manner the world's carpet of humanity, we shall now return to earth and see what we can ascertain concerning when and how it came to be woven. It is the "when" rather than the "how" which concerns us in the present hour. The belief is still general that it is not many thousand years since the world became populated by the races of modern man. Such a belief is not illogical. When we try to imagine what has happened in the past we must base our speculations on what is taking place under our eyes at the present time. There is a restlessness, a migratory instinct inherent in a considerable proportion of every population. I dare think that in Birmingham there are to be found not only natives of every county of England, but that most of the Welsh, Scotch, and Irish counties are also represented. Birmingham has not only received, it has also given. If it resembles other towns it has sons and daughters throughout the world. The objection will be at once made to this train of reasoning that the migratory tendency alluded to is of recent origin—that it is a result of our modern civilisation. Industrial or individual migration is a new condition, but predatory or collective migration has evidently been in existence as far into the past as history or tradition can take us. Amongst more primitive races of man—and it is they who give us the key to the early state of civilised races—there lurks a deep-rooted tendency to collective migration. When we realise the rapidity with which a people may multiply and the tendency inherent in all human races to migrate, it is conceivable that mankind may have spread from a centre and occupied the whole earth in the space of a few thousand years.

The discoveries which have been made during the last 50 years clearly indicate that the distribution of mankind and their separation into widely different races have not been a rapid but a very slow process. Thanks to the labours of the Archæological Survey of Egypt, to Dr. Reissner, to Professor Elliot Smith, Dr. Wood-Jones and Dr. Derry, we know something of the people who occupied the Lower Nile Valley during the last 8000 years. At every phase of that long period there was found evidence of the arrival of new types—of migrations or invasions of Egypt—but there was also clear evidence of the survival of the old types. There was evidence of mixture, but the final conclusion to be drawn from a study of the ancient inhabitants of the Nile Valley is that the passage of 8000 years left the prevailing human types modified to only a slight degree. Recently Dr. Seligmann has shown that certain native tribes near Suakin on the Red Sea have features and bodies very similar to the predynastic Egyptians. The explorations of Mr. Henry S. Wellcome in ancient cemeteries of the Soudan have demonstrated that the peculiar, tall, slender, long-limbed negro tribes which now occupy the upper waters of the Nile were there at least 2000 years ago. The lesson that Egypt has to teach us is that human types are not easily changed. The explanation which is usually given—and I am prepared to

[1] THE LANCET, Sept. 13th, 1913, p. 785.

accept it—is that the conditions of life along the Nile Valley have remained unchanged during recent millenniums, thus ensuring the permanency of the human type.

When we turn to America we find further evidence of the permanence of human types. In recent years Dr. Ales Hrdlicka, of the Bureau of American Anthropology, has written two excellent memoirs on the remains of ancient human skeletons which have been discovered in the New World. Of those discoveries I propose only to cite one—the human skeleton discovered at Lansing, in the State of Kansas, 11 years ago, in a glacial deposit at a depth of 23 feet. Dr. Frederick Wright, who has given a lifetime to the study of glacial deposits in North America, and especially to the antiquity of man in that country, regards the deposit under which the skeleton was found as formed before the last cycle of glaciation, and gives its probable antiquity as about 12,000 years. If the European cycles of glaciation were contemporaneous with those of North America, then the antiquity, if I may infer from the estimates given by our own geologists, is very much greater than has been calculated by Dr. Frederick Wright. No one has ever called in question, no one can call in question, the authenticity of the age of the Lansing skeleton. Dr. Hrdlicka, however, rejects it as representative of ancient man in America on the ground that "this man was physically identical with the Indian of the present time, and that his physical characteristics during all the thousands of years assumed to have passed have undergone no important modification." We see from that statement that Dr. Hrdlicka is under the belief, one which is widely held at the present time, that human types are so liable to variation that it is impossible for them to breed true over a long space of time. We must accept facts as we find them and suit our beliefs to fit our observations. The plain lesson of the Lansing find is that before the last great glacial cycle there existed a type of man in the central States almost identical with the modern Indian of the same region.

THE EARLY PEOPLE OF ENGLAND.

When we come to study the history of our own countrymen we reach a similar conclusion. Our archæologists are opening up Anglo-Saxon cemeteries of the fifth and sixth centuries and revealing to us the physical characters of the people who gave us their language and their blood. Their teeth were better than ours, their limb bones are usually rather different in conformation, but the counterparts of those people are to be seen on every hand at the present day. Every year we come to know more of the people who inhabited Britain in the Roman period; they are the same kind of people as ourselves; their heads showed the same variety of forms as may be seen in Birmingham to-day. When we go further back, to the time before iron was used and weapons were made of bronze—to a date which takes us some 2000 years before the birth of Christ, we find human types with which we are still familiar. Those handsome men with high, rounded heads, whom we now know as squires and men in posts of authority, first appear in our country at this date. They were originally natives of Central and Eastern Europe; they were not a new type of man—only new to England. When we go further back and explore those mounds or barrows which contain the men who lived in England in the Neolithic period we do not find new types; the men of that time, except as concerns the state of their teeth and shape of their limb bones, were at one with us. Five thousand years ago the men of England were of our stature, had the form of head and the strength of muscle which has been given to many of us.

When we pass beyond the Neolithic period to reach the time when only stone implements of the more ancient or palæolithic type were used, we were supposed, until a few years ago, to come to a blank or hiatus in our knowledge. That blank is in the process of disappearing. Recently Mr. Reginald Smith, of the British Museum, has recognised that the flint implements which were left by the men who dug those peculiar pits at Cissbury and in other parts of England were not early neolithic people as is usually supposed, but were in reality palæolithic folk. Now we know some of the skeletons of these early Englishmen; they were men exactly of the common British type. Lately I had an opportunity of examining two discoveries of human remains from Kent which were so similar that they might have been almost members of the same family, yet we are fairly certain that they belong to very widely separated periods. The remains of one set of people were discovered at the base of an ancient stone monument at Coldrum, in Kent, within the valley of the Medway, by Mr. F. J. Bennett, F.G.S. Only worked flints of a neolithic type were found during the excavations; we may, therefore, presume that the people who were buried in the ancient tomb at Coldrum were Kentish people of the Neolithic period. The more ancient skeleton was discovered a short distance from Coldrum, near the little town of Halling, situated on the Medway, a few miles above Rochester. At Halling the Medway is flanked by a terrace of brick-earth, laid down at some previous period, when the Medway flowed a number of feet above its present level. This terrace had to be cut through when a new sewage system was being constructed for Halling. The terrace was seen to be made up of a number of superimposed strata or layers, each layer or stratum being of different composition, and therefore marking a separate period in the action of the river. Beneath the fourth layer, counting from the surface, were found charcoal, charred stones, and remains of hearths, with worked flints which belong, not to the neolithic, but to the palæolithic type. They are similar to those found in the floor-strata of French caves, and are of the type assigned to that palæolithic phase of culture known as Aurignacian. The upper four layers had thus been deposited over an old habitation of the men who lived before the close of the Palæolithic period—who actually were in Kent towards the close of the last cycle of the Glacial period. In the fifth stratum, at a depth of almost 6 feet from the surface, was found a human skeleton, which has been preserved and investigated by Mr. W. H. Cook and Dr. Spencer Edwards. To me it is clear, from the flexed posture of the skeleton, that they were dealing with a burial, but not one made by modern men from the present land surface, but one made from the ancient land surface by the palæolithic men who lived before the last four layers of the terrace had been deposited. A full investigation of the skeleton showed that the palæolithic man of Halling was very near akin to the neolithic people of Coldrum, and yet the years which elapsed between the periods at which the one and the other lived must be counted in thousands. A few miles north of Halling, in the valley of the Thames, is Tilbury. When the docks were excavated an old land surface was reached at a depth of 32 feet; two feet below this old land surface was found the skeleton of the Tilbury man. He belongs to that form of ancient Briton to which Huxley gave the name of "river-bed" type; he is first cousin to the men who have long lived on the shores of the Mediterranean and which Sergi has distinguished as the Mediterranean race. The remains found at Halling and at Coldrum may also be assigned to the river-bed type. This type was not confined to the south-eastern part of England. From the old forest land now submerged along the western and southern coasts of England human skulls of this type have been recovered. The skull found in the Cheddar caves and described by Mr. Davies as belonging to the closing phase of palæolithic culture is of the same class. Some 60 years ago, when a cutting was made for a new railway near Mickelton in Gloucestershire, a skull of this type was found at a depth of 10 feet, beneath peat and undisturbed blue clay—certain indications of a great antiquity. A few years ago the Rev. E. H. Mullins explored a small limestone cave which lies in a narrow valley behind his rectory at Langwith Bassett in Derbyshire. In the cave he found numerous remains of animals—many of them now extinct—and clearly belonging to the geological period preceding the present—the Pleistocene period. He found worked flints and a human skull. The skull was of the river-bed type, but its condition was so fresh that at first I was inclined to think some mistake had been made. Mr. Mullins, however, showed me that the condition of preservation of the skull was exactly the same as that of the bones of the extinct animals. It is probable that the Langwith cave skull is of the same age as the Halling skeleton; both appear to belong to that period of palæolithic culture—the Aurignacian. How long ago it is since the Aurignacian period closed we have as yet no accurate means of judging, but those who have studied the changes which have occurred in our valleys and in our fauna suppose that we must make a liberal allowance of time—30,000 years or perhaps more.

THE ANTIQUITY OF MAN.

We have thus surveyed the history of the men of three parts of the earth over a considerable period of time. In all three places the result has been the same—we see the same persistence of type in Egypt, in America, and in England. In this hall to-night there are representatives of the men of the Derbyshire cave and of the Halling terrace; in America the Red Indian preserves the form of men who lived before the last glacial invasion of North America; the predynastic Egyptian survives in the tribes on the shores of the Red Sea. We may, therefore, suppose that if inquiry were made in China, in India, or in Central Africa the result would be the same—that in Central Africa we could follow the Negro type well back into the Pleistocene period; in China the Mongolian type, and in India the Dravidian. It is when we come to realise the persistency of human types that we see that we must allow a very long period indeed to cover the time needed—not for the population of the world, but for the differentiation of modern man into the well-marked races with which we are all familiar. The characters which separate the European, the Chinamen, the negro impress every one of us; we cannot overlook them. Yet when we come to examine those races structurally we must admit that they are so much alike that we must suppose, to account for their community of structure, that all three have come from a common stock.

The question we have to face in solving the problem of the antiquity of the modern races of man is, How long will it take for the separation of an African, an Asiatic, or a European, from a common stock? It is evident, from what we have discovered concerning the fixity of human types, that it will take a long period—infinitely longer than most modern geologists will allow.

When we approach the problem of the antiquity of man from the side I have tried to present to you, we obtain some assurance that the human beings who represent the common stock from which all our modern races have diverged could not be of a very low type. When we come to study the features which characterise the brains of the various human races—so far as these differences may be detected with the naked eye—we see that they relate to structural details. In their main features they are alike. It is true that a skilled anatomist will, if you show him a representative specimen, distinguish the brain of a negro from that of a European or from that of a Chinaman; I do not think, however, he could tell with any degree of certainty the brain of the Chinaman from that of the European. Seeing that the brains of all modern varieties of men are so much alike in the essential features of their architecture, it is a legitimate inference, I think, that a large and moderately complex brain is a common inheritance of modern races—that in the common stock from which all modern races have arisen a fairly large human brain must have been already present. We, therefore, ought to find even before the differentiation of the present races of mankind that there were human beings in existence with large brain already.

I am now to lead you on to another aspect of this problem which is hotly contested at the present time. In tracing backwards the ancient inhabitants of England, I left off with the remains which are assignable to the later part of the Pleistocene period. I now propose to advance well into that period. In the valley of the Thames there still persist, in the form of a gravel terrace, remnants of an ancient bed of the Thames. It is known as the 100-foot terrace because it is situated about that distance above the level of the Thames. About the geological age of that terrace, at least its deeper strata, there is no dispute; it belongs to the earlier half of the Pleistocene period. Now it was in that terrace, at a depth of 8 feet, in strata which contained worked flints belonging to an earlier form of palæolithic culture, and with remains of pleistocene mammals, that the Galley Hill skeleton was discovered. The remains are those of a man of our type. It would not be easy to find his match in our present population; I doubt if anything approaching a counterpart to him could be found, but he could appear in a modern company without his features calling forth any special remark. The remains were discovered in 1888. Some years before a fragment of a human skull was unearthed in a deposit of brick earth near Bury St. Edmunds at a depth of 7 feet. With it were found mammoth tusks and implements of the Acheulean type—a culture which belongs to Middle Pleistocene time. It is only a fragment, but there is sufficient of it to make us certain that the original skull of which it formed part was shaped as in modern human races. Two years ago Mr. J. Reid Moir, of Ipswich, discovered a human skeleton beneath an undisturbed layer of chalky boulder clay 3½ feet in thickness. The skeleton lay in the flexed posture, and probably represented a burial, but it was one made before the chalky boulder clay was laid down. That is a deposit following the great glaciation. The skull and skeleton have the features of modern races, all except the tibia—that was shaped differently to any human tibia I have yet seen. The Ipswich skeleton represents a man of the modern type. Thus, in my belief and in that of many competent men, we have discovered in England representatives of modern man in existence in England, even before the middle of the Pleistocene period.

By Professor Boyd Dawkins and Dr. Smith Woodward such discoveries are regarded as impossible; with Dr. Hrdlicka they think that a human type could not persist from the Mid-Pleistocene to the present day unchanged. In their opinion all the human remains just mentioned represent Neolithic burials. Our Neolithic ancestors took the trouble to dig a grave 8 feet deep in the 100-foot terrace, and laid the strata down again so carefully that we cannot now detect their forgery. The Neolithic men of Bury St. Edmunds laid a fragment of a dead man's skull 6 feet deep in brick-earth with mammoth tusks and Acheulean implements to delude a simple set of men in the twentieth century into believing that mankind of our type was ancient!

NEANDERTHAL MAN AND THE PILTDOWN SKULL.

Another obstacle to the belief in the antiquity of our own type of mankind has been removed in recent years. I may describe it as the Neanderthal bogey. A certain school of geologists became obsessed with the belief that it was impossible for any species of mammal to come through a long geological period unchanged, and inferred that man could not escape so universal a law. The discovery of that extraordinary type of mankind over half a century ago—the type which is now known as Neanderthal—confirmed this belief. To a superficial eye Neanderthal man was just the individual wanted to represent our stage in evolution during the Pleistocene period. He had many simian features which we do not possess. We have come to realise now that he had also many high specialisations, and that he cannot stand in the direct line of our ancestry. We know him now as a being quite distinct from all modern races; the difference between him and us is much greater than between a European and a negro; he represents a totally different form of human being. We now know his culture and his period. We have followed modern man right up to the threshold of the period at which he lived; it is also clear that he died out in front of modern man in the same way as the Tasmanian disappeared before the European. Neanderthal man does not represent our Pleistocene ancestor. Where, then, is our pleistocene ancestor if not at Galley Hill, at Ipswich, and at Bury St. Edmunds? These remains were found in older deposits than those which contain the remains of Neanderthal man. In Italy it is the same as in England; human remains of our type have been found, but they have been rejected because they were not of the Neanderthal type.

The remarkable skull which was found at Piltdown by Mr. Charles Dawson and which has been described by Dr. Smith Woodward, is destined to throw a new light on the problem of man's antiquity. It was found in a very shallow deposit, little more than three feet below the surface of the ground. If it had so happened that this skull presented modern characters, what would have been said of it? I am certain that Professor Boyd Dawkins, Dr. Smith Woodward, and Dr. Hrdlicka would have regarded it as a recent burial. If its high degree of fossilisation had been brought to their notice they would have replied that fossilisation was a most uncertain indication of antiquity; they would have cited bones from neolithic burials which show mineralisation to an equally great degree. If it was pointed out to them that the remains found with the skull were those of extinct animals belonging to the Pleistocene period they would have replied that a recent burial may be made in a Pleistocene stratum and bones of different ages thus mingled. I draw your attention to those aspects of the case of the ancestor of

modern man—he is sentenced before his trial begins. In the case of the Piltdown skull, characters are present which mark its ancient date. No modern man has such a chin or lower jaw; and if Dr. Smith Woodward is right in assigning the canine tooth found at Piltdown to this jaw no human being has been seen with such a simian canine tooth. In many features the Piltdown man foreshadows our type. Does he, then, represent our ancestors near the beginning of the Pleistocene period, admitting for the sake of argument that the Piltdown man is Pleistocene and not Pliocene in date?

The opinion I have formed is that he does not lie in the direct line of our ancestry. I base my opinion on the fact that we know of the remains of two different species or genera of mankind in Europe at the beginning of the Pleistocene period—one is the Heidelberg man, the other is the Piltdown. The Heidelberg man was certainly of the Neanderthal type, the Piltdown man is much more of our own type. They are clearly products of a common stock. We must presume, from what we know of man's nearer relatives—the anthropoid apes—that the common ancestor of Piltdown and Heidelberg man possessed the ledge-like overhanging eyebrow ridges which characterise the anthropoid forehead. These ridges have disappeared in the forehead of the Piltdown man; they have been retained by Neanderthal man. On the other hand, in the Heidelberg jaw the region of the chin already shows human modifications; the Piltdown man retained the simian form. There is, if we may use Mendel's law for this purpose, apparently at least one intermediate descendant of the common Piltdown-Heidelberg ancestor missing—one which shows the human modification of the chin and the disappearance of the ledge-like supra-orbital ridge. That missing form would serve well as our ancestor. We must, then, not dismiss as neolithic burials those human remains which have neither simian eyebrow ridges nor simian chins. I still maintain, as I did before the discovery of the Piltdown skull was made, that the Pliocene ancestor of modern man was one probably as highly evolved as the aboriginal man of Australia.

An Introductory Address

ON

THE PROBLEMS OF UNIVERSITY MEDICAL EDUCATION IN LONDON.

Being the Annual Report of Charing Cross Hospital Medical College presented at the Opening of the Winter Session on Oct. 1st, 1913,

BY W. HUNTER, M.D. EDIN., F.R.C.P. LOND.,
DEAN OF THE COLLEGE.

[Dr. Hunter in the first part of his report briefly reviewed the results of two years' experience of concentration of the earlier medical studies, as adopted two years ago, by transferring its students for this purpose to the University of London, King's College Laboratories, immediately adjacent to the school. The result has been a marked increase in students from a total of 109 in the school in the year 1910–11 to an average of 150 during the past two years. The school is now practically entirely medical, the dental students for the most part having passed to the two or three schools in London which are especially interested in dental education, increasing their prosperity, while this loss to Charing Cross Hospital Medical College has been compensated by a still larger increase in the number of medical students. Of these nearly one half of the full-time students are now, moreover, studying for the degree of the University of London. The preliminary science laboratories of the hospital, freed by the concentration plan, have been devoted to the bacteriological and public health departments of King's College, and the school is enabled to make a grant of £250 a year out of the rent received therefor to the university laboratories. As to the disadvantages attaching to the concentration method, Dr. Hunter knew of none; even the fears of its interference with the social life of the hospital and school have proved groundless, for the interest in the Students' Union and its many spheres of activity and in athletics has never in the history of the school been more active and intense. The result has justified the opinion expressed by Dr. Hunter in his last annual report, when speaking of these changes as constituting an experiment in connexion with university medical education, that the new policy meant not "the breaking up of the school, but the making up of the school." Dr. Hunter, in the second part of his report, went on to deal with the Problems of University Medical Education in London.]

THE UNIVERSITY OF LONDON AND THE SCHOOL HOSPITALS.

Medical Education has been a welcome guest and has had a free run in all the school hospitals from the very first. This is in striking contrast to the experience of medical teachers elsewhere—e.g., in Berlin, the capital of Germany, where all the hospitals refused to allow students to make use of them, and early in its career (25–30 years ago) the Government was in consequence compelled to build the great Charité Hospital of Berlin—at first for its own war purposes and now maintained for University purposes. Still more in America up to the present time, where the greatest difficulties are put in the way of medical schools by the governors of hospitals refusing or limiting their permission for students to attend. In return for their free use by the University, the hospital governors in London have never asked or received any material or other recognition from the University.

This freedom of the hospitals throughout the whole history of English medicine forms the basis of the chief English clinical traditions of medical education.

[Dr. Hunter here quoted several passages from the evidence of Mr. Abraham Flexner before the Royal Commission showing that the clinical training is immensely better in England than in any ordinary school in America, and that in some respects conditions are distinctly more favourable to the student than they are in Germany, concluding with the observation that there seemed to be nothing here materially wrong with English methods, and particularly with the relation of hospitals to medical education.]

THE GREAT TASK OF THE LONDON SCHOOLS IN MEDICAL EDUCATION.

How great the task of London medical education has been, and still is, is shown by figures and statistics which I placed before the Royal Commission. The medical schools of London, up to as recently as 20 years ago, were responsible for the entire medical education of no fewer than 70 per cent. of the total students of England and for the part-time education of another 10–20 per cent.—of no less than 80–90 per cent. of the students in England, this number constituting no less than 42 per cent. of the entire students of England and Scotland. Despite the formation of seven provincial Universities during the past 10–15 years, it still has to educate, in whole or in part, over 70 per cent. of the total students in England and over 40 per cent. of the total students of England and Scotland. The medical schools of London have thus discharged in the past, and still continue to discharge, a big task for English medical education, and they have done this under great and increasing difficulties without endowment and without the slightest pecuniary support from the university whose students they educate. What, then, is the chief problem presented by university medical education in London? It is represented to be the hospitals of London—their number, their intense interest in education, their multiple energies, the difficulty of reconciling their existence and their energies with the grafting on to them of another system of education and hospital control necessary, it is alleged, for the establishment of an ideal system of university medical education.

[Dr. Hunter again quoted Mr. Flexner's evidence as showing the defects of the British system from the educationist's point of view—viz., the need for the University to have complete control of its own hospital, to make England a contributing factor of the progress of medicine. Clinical teaching had failed to keep pace with laboratory improvements in medicine, and such productivity as had occurred had been in spite of the system. What was needed was greater prominence for the educational aspect of the training. London hospitals were disorganised as a whole and individually. A reorganised faculty would soon reorganise the wards.]

Here, then, the picture of English medical education as it is drawn by a distinguished American educationist (not a doctor) is sharply outlined. If the shadows are too deep in places and wrongly placed his object is the highly laudable one, beneficial to education, of directing attention to the existence of the picture at all—not necessarily to its completeness or absolute technical accuracy.

The problems facing University medical education in London, as here presented, are thus the following formidable ones: 1. To create, in the first place, a university which will be concerned and *financially able* to give any education at all to its students in their final hospital and school studies. For this the University of London has, so far, never done. 2. To create a *new Senate*, limited in number to 10 or 15 men, with the fullest financial, administrative, and executive control over the whole affairs of the University. 3. To create a new *Faculty of Medicine*—small, compact, and sufficiently business-like in its methods to be able to draw up a scheme, enter on negotiations with one or more hospitals, and induce them to hand their hospital over to them for university purposes. 4. As regards the hospital governors, the problem placed before them by the newly organised senate will be to allow this university faculty to modify their entire existing arrangements in some radical manner to suit university requirements—in short, to control the hospital; while the hospital managers continue, as before, to raise all the money necessary to keep the hospital going. 5. There is a further problem—most clearly presented by Sir William Osler in his evidence before the Commission. He was asked: "Supposing the hospital governors refuse to hand their hospital and its control over in the way suggested, what influence of a compulsory character could you bring to bear upon them?" and the reply was: "I do not know, Sir."

NATIONAL CHARACTERISTICS IN MEDICAL SCIENCE.

National characteristics play an important part in medical science as they do in all other spheres of human activity. They have played an all-important part in the development of English medical education and medical observation. In the case of English medicine, that characteristic has been *individualism*—shown in connexion with the foundation alike of hospitals and schools, and no less manifested by the individual philanthropy which originally created and still underlies and supports the English hospital system. In the case of Germany the national characteristic has, on the contrary, been essentially governmental and bureaucratic, all hospitals and medical faculties being supplied and maintained by combined State and municipal aid. In America there has been exhibited individualism—rampant to a degree quite unknown in the history of any country—condoned, connived at, and even legalised by a degree of recognition and support on the part of individual States and municipalities totally unknown in the history of medicine in this or in any other country.

MEDICAL EDUCATION IN AMERICA.

No greater service has ever been rendered to American medicine than the full, clear, and remarkable exposure recently (1910) given by Mr. Abraham Flexner of the proprietary nature of scores of the medical colleges, "institutes," quasi-universities, "national medical universities," "colleges of physicians and surgeons," &c., which for many years have given their M.D. in a frankly commercial spirit.

[Dr. Hunter here referred to the case of the "National Medical University," which according to Mr. Flexner, had "no equipment of any sort, and a dirty, unused, and almost inaccessible room as its dissecting room; and its 'hospital' consists of a top floor containing two lonely patients,'" yet it enjoyed from students' fees an (estimated) annual income of £4500.]

The evil of medical education in America—namely, individualism and individual "schools" and "colleges" run rampant—has been signally checked, and is in process of being in due course effectively arrested by a still greater individualism originally created by the munificent foresight of one philanthropist, Johns Hopkins, and given effect to by the brilliant imagination and practical genius of a young pathologist, Professor Welch, to whom at the early age of 28 was entrusted the unique task of formulating the conditions and selecting the professors for the first Faculty of Medicine to govern the new "Johns Hopkins Hospital and University" of Baltimore. His first selection was a young Canadian physician professor, educated in the McGill University of Montreal and in London in the best clinical traditions of English medicine, transferred to the University of Pennsylvania in Philadelphia, thence transferred to the Johns Hopkins University in Baltimore, and finally finding his present home in the ancient University of Oxford—Sir William Osler.

I have recently elsewhere, in the opening address of the McGill University, Montreal, in 1910, paid my tribute to the influence of these two great teachers on the science of medical education. "Under their inspiring spirit and guiding hand, supported by their enthusiastic colleagues and pupils, Anglo-Saxon medicine on the American-Canadian continent has shown itself capable of combining in a degree unknown to English medicine the scientific spirit underlying German work and methods with the great clinical practical outlook which throughout its whole history has specially characterised English medicine." That tribute paid three years ago, without any reference to the problem of medical education in London, has an interesting significance at the present time. For it practically embodies the *Leit-Motif*—the note of "Fate and Gloomy Sorrow" which runs through the whole of the evidence of the Royal Commission on the University of London with regard to medical education—the *motif* which has eventually determined their final recommendations. That *motif* is the excellence of English clinical traditions in hospital work; but the extraordinary defectiveness, insufficiency, inadequacy, absence of organised support, whether from Governmental and public services, or by public opinion, or by private generosity, for the provision for laboratory work and research necessary for the promotion of medical education or the advancement of medical knowledge.

What, then, was the antidote which these pioneer workers introduced into medical education in the United States as they found it in the "eighties," where it still exists—to a degree quite unknown in English medicine. It was the following: that Sir William Osler introduced the clinical traditions of clinical teaching—by the system of clerks and dressers in the wards and continuous relations with and observation of patients; while Professor Welch grafted on to that system the all-essential, supporting, educational, and progressive system of great laboratory institutes created on the lines of German methods and example. This was possible in their case, for they had a clean slate to write upon—a free hand both as regarded money for their hospital and school and as regarded the organisation which they saw fit to adopt.

THE ROYAL COMMISSION'S PROPOSALS.

The proposals now submitted in evidence before the Royal Commission on University Medical Education in London and ultimately adopted and recommended by the Commission are shortly—that similar organisation is necessary to create the proper conditions for placing hospital education in London on a university basis.

Inasmuch as the chief basis of the English system is the clinical traditions of hospital education—the system of clerks and dressers and facilities for hospital work and assistance always freely granted by hospital authorities in this country is admitted by all to be immensely superior to the system obtaining in any other country—it might be thought to be perfectly easy and practicable to graft on to this system for university purposes the laboratories, professors, and assistants necessary to supplement and complete the system. I think myself that that is perfectly practicable, and the matter, having now been referred to a strong Departmental Committee of the Board of Education to draft a Bill to carry this into effect, so far as this portion of university education is concerned, I am quite prepared in common with everyone interested in placing university education on a sound basis in London, to afford them every help in my power. The character of the Departmental Committee is, to my mind, a sufficient guarantee that the distinctive national characteristics and honourable traditions of English medicine (which have been far more fruitful in advancing medical knowledge than some of the sweeping generalisations submitted by witnesses before the Commission realise) will have due weight attached to them.

Still more I am satisfied that the widely different conditions of hospital management and support peculiar to this

country and quite unknown to Germany and institutions like the Johns Hopkins Hospital and a few American hospitals—to wit, the voluntary public charitable support and government of the hospitals in this country as contrasted with the State, municipal, bureaucratic control of the German, and the endowed support and control of the newer American hospitals and universities, like the Johns Hopkins—will be better known to, and more fully weighed by, that committee than they could possibly be known to, or weighed by, witnesses unacquainted by practical experience with their working.

To pour new wine into old bottles is proverbially a risky business—which it is said no wise man would attempt to do. To pour a German full-bodied wine compounded of full control of the Minister of Education, Exchequer control in connexion with insurance money, municipal control, and autocratic directing control of two or three professors over the whole of a hospital and of all the laboratories connected therewith, would certainly burst the old bottles (quite decent and useful ones) of the entire voluntary system of hospital support and government existing in this country.

The problem is one of the greatest difficulty. So far from subjecting the Commission's Report to criticism, with regard to the individual recommendations, my own opinion is, after the closest perusal of the whole volumes of evidence submitted, that a satisfactory solution of the whole problem of University Reform in London, including that of Medical Education, is to be found in connexion with its fundamental recommendations, in my judgment admirable in character. These are:—(1) Government of the University Court; (2) its Finance Administration and Executive control by a compact and limited Senate of 17 business men (instead of an unworkable Senate of nearly 100 men representing independent and, in many cases, opposing interests); (3) the creation of a small compact Faculty of Medicine, not merely advisory, but made responsible for the Educational arrangements and provisions subject only to the control of the Senate so far as their Regulations affect the finances of the University.

FINANCIAL NEEDS OF MEDICAL EDUCATION.

The needs of a school are determined by the requirements of full-time students, who are engaged in work in the school and hospital all day. Part-time students, who come for shorter periods of time, share in the arrangements thus provided to their own great advantage, and contribute to the support of the school. 1. To place medical education on a sound basis the fees thus earned, plus any educational grants given by the Board of Education, should be entirely available for the education of the students and for payment of lecturers and demonstrators. On the basis of what is being done in German universities and a few of the schools in America, to which so much attention has been drawn as examples of what the standard of university education should be, these ought to constitute about one-third of the total annual cost of a student's medical education. 2. But this alone is quite inadequate. In addition there is required money for the provision, equipment, and support of the laboratories required for instruction and for payment of the salaries of the professors in charge of the various departments. The amount required for this is about the same as that earned in fees. 3. And, lastly, over and above these requirements there should be a third quotient connected with medical education, available for the promotion of research in the various departments.

ANNUAL EXPENDITURE PER STUDENT.

I estimate, on the basis of practical experience, that the current annual expenditure for university medical education in London should work out to at least £70 to £80 a year per degree student, or approximately £80,000 to £100,000 a year. No provision approaching this is available in any of the medical schools of London. It means that two-thirds of the cost of education must come from sources other than fees. Owing to the absence of any adequate support from the State, university, or municipal or any public sources, no such funds are available.

The requirements here stated may seem to be large and costly even for a rich country like England. Nevertheless, they fall below the actual expenditure on medical education in the universities of Germany. According to official figures supplied by the German Government, the actual expenditure in 10 universities in Germany amounts to no less than £95 per student, and a total sum of over £500,000 per annum.

COMPARISON BETWEEN A GERMAN AND A LONDON SCHOOL.

[Dr. Hunter then compared the expenditure at the University of Königsberg (370 medical students) with one of the largest London schools (353 full-time and 170 part-time students). The German expenditure was £34,000, or £92 per student annually; the English £14,000, or £40 per student. The State in Germany contributed £23,500, or £63 per student; the Board of Education in England £4600, or £13 per student. Further, the German University contributed £29; there was no university contribution in England. The departmental expenditure in the German university was £24,500, of which £14,000 were for clinical salaries, teaching, and work; in the English school £6000, of which only £1500 were available for clinical teaching.]

There is not much comforting in this contrast either to the English Government or English public opinion. In my opinion the financial conditions of medical education in this country are a discredit to all parties concerned, except only the medical schools and their devoted band of teachers who support the whole cause of medical education in London on behalf of 70 per cent. of the total students of England, under greatest difficulties, without financial support, without recognition, and without even sympathy.

If I might venture to make any criticism on the Final Report of the Royal Commission it would be that this financial aspect of medical education in London has not been brought out in connexion with the comparisons of a startling and invidious character between English medical education and German medical education to which so much weight has been attached. The prosperity of university medical education in London would be enormously promoted by providing three to nine professors in certain selected schools of London, each of them with £4000 at its disposal for the development of medical and surgical science and teaching in the University, as proposed by the Royal Commission. The total sum of £36,000 a year thus provided for salaries and working expenses would not, however, solve the problem which it is sought to solve—salaries to full-time professors and their assistants, and the providing and maintaining and paying adequate scientific and final laboratories connected with the schools selected. It is little more than that referred to in the expenditure on one moderate-sized German university. And this is apart from any capital outlay necessary for the provision of new laboratories.

[Dr. Hunter next compared the annual current expenses of 10 medical schools in London with 1122 full-time and 765 part-time students, with those of the Medical Faculty of the University of Berlin with Charité Hospital (2000 students), and the respective State grants in each case, showing the grant to be about £12 per full-time student in London as against £49 in Berlin.]

THE BOARD OF EDUCATION AND THE MEDICAL SCHOOLS.

Small as this grant is relatively, it has been of the most material help to every school which has been in receipt of it. In the case of the Charing Cross School, as I can testify from personal experience, it has made all the difference in the world in enabling it to carry out the reorganisation which has had such encouraging results in relation alike to the University, to King's College, and to the school. The increase of efficiency, equipment, laboratory accommodation, facilities for teaching and research which it has helped to bring about for the benefit of 250 students of the school and the University laboratories who have had the advantage of them during the past year has been very great. Apart from the amount of the grant itself, and the increased efficiency thereby produced, it has given the school great encouragement to know that for the first time in their history a great public department of the State is interested in their work for medical education and the provision made for carrying it out effectively.

It is only some four or five years since the Board first began to make their grants. The information which they have yearly before them, and which they so carefully analyse and report, has been of the greatest service to the cause of medical education and its university reform—the facts brought out have given the greatest stimulus to better efficiency which the medical schools in their history have ever received.

Presidential Address

ON THE

RELATION OF MEDICAL KNOWLEDGE TO WAR CONDITIONS.

Delivered before the United Services Medical Society at the Royal Army Medical College, Millbank, on Oct. 9th, 1913,

BY COLONEL BRUCE M. SKINNER, M.V.O.,

COMMANDANT OF THE COLLEGE.

GENTLEMEN,—I have to express my thanks to the society for the honour they have done me by placing me in the chair as their president for the current year. The diffidence one feels on taking up such a position inspires the resolve to do one's best to prosecute the valuable work of this society. Very valuable work it is—perhaps especially valuable to us in London. Here the subject-matter of our debates is usually the practical application of our services on the Flood and in the Field. This gives an opportunity to all of us who are engaged in the very serious pursuits connoted under the general term "medical" to discuss the methods of bringing our technical knowledge to the aid of the sailor and the soldier under war conditions. Many of us have no opportunity of seeing war or even its peaceful presentment at manœuvres; for this reason I submit that our discussions are specially valuable to those who live in London. Our branches are in closer touch perhaps with the practical aspects of the Royal Navy and the Army, and can see actually many of the various phases of what is called the military medical problem. Those who have but occasional personal experience gain by these discussions a view of the actual performances in war; they hear the difficulties of applying principles to varying situations, and learn thereby the value of that initiative which enables a man to adapt himself and his appliances to varying exigencies. Like the student of medicine the army doctor learns the principles laid down in his text-books—i.e., regulations and training manuals; he becomes educated. His education is incomplete unless he has trained his mind to apply and adapt broad principles to suit circumstances which vary from the normal.

Reading through the Proceedings of this society I have been much struck by the way in which they afford illustrations of the varying conditions of war, of the different circumstances which any one of us may have to meet; they offer solutions of problems which cannot fail to have their value when we may be placed in a position demanding prompt action; they contain suggestions which may lead to advances in organisation and arrangements, advances demanded by the progress of thought. Here a little and there a little, one may pick out methods or means of overcoming what would be grave difficulties to inexperienced men who have lived in their shells and not polished their wits by conference and discussion with their fellows. The problems of life are not set upon an undeviating line of railway; the problems of war are as varied as the problems of civil life.

THE MEDICAL SITUATION OF THE BATTLE OF SPICHEREN.

I submit, therefore, that we are fulfilling a rôle which will prove useful to all commissioned medical officers, and would express a hope that naval and military medical problems may still engage a large portion of our time and thoughts. And in this connexion I would like to quote a passage from the German official account of the battle of Spicheren describing the situation at Spicheren on August 6th, 1870:—

> At the commencement of the action the whole of the battalions of the foremost brigade (v. François) were employed in attacking, as simultaneously as circumstances would allow, the front and the flanks of the adversary's position. As it then became apparent that these forces were insufficient for the purpose, all reinforcements had to be drawn from the brigade (v. Woyna) which followed. The arrival of the latter at various points of the line of battle mixed the brigades and rendered the exercise of command very difficult, especially on the right wing, where the battalions of different regiments had already become intermingled.

These brigades were of the 14th Division of the VIIth Army Corps. This was comparatively early in the fight. If you will pursue the sequence of events you will find the IIIrd and VIIIth Army Corps coming up and mingling with the VIIth as their units or companies arrived, and you will see portions of the 5th, 13th, 14th, and 16th infantry divisions commingled, and a casualty list of 4871 Prussian officers and men, to say nothing of the wounded left behind by the French, scattered across a front of some 3 miles, with a depth of roughly 1½ miles, in forests and ravines and upon mountain slopes. You will observe also that the whole German Army had on its approach to the battlefield only two bridges at Saarbrucken, and you can picture to yourselves the position as regards the rearward evacuation of the wounded.

When perusing this account again very recently this passage, taken in conjunction with the preceding detail, struck me as offering food for thought, more particularly, perhaps, to the battalion medical officer, and I determined that on this present occasion I would suggest that one of our members might undertake to give us a paper descriptive of the fight and of the field medical requirements. We should then have a picture of a series of real tactical positions resembling those which some of us might experience in the future, detailed as to time and space, which important factors are often lost sight of in academic exercises, while the medical problem might be approached as if the battle occurred to-day with our modern organisation, embracing the Territorial Forces and the voluntary aid afforded by the Central British Red Cross, working through the various situations confronting the battalion medical officer up to those with which the officers of administrative rank would have to deal. I have prepared a map of the positions at the height of the battle in the hope that it may help to attract someone's interest sufficiently to induce him to give us a paper.

TACTICAL AND SANITARY PROBLEMS.

We owe much of our success to the officers of the Territorial Force who have made us familiar with the problems with which they have been faced, and I hope they will continue to widen our knowledge by their papers, which possess the immense value of showing us how closely we are associated in our spheres of work. Also, it is hoped that our Colonial brethren will make use of our society when they are over here, and furnish us with matter which will assist in coördinating our work so that it may assume an Imperial scope. I may add that information as to the dates of our meeting may be obtained at any time by applying to our honorary secretary at this College.

The September number of the journal of the Royal United Service Institution contains a paper upon the Organisation of a Division, which offers fair grounds for criticism from our standpoint. Without attacking that problem directly now, I would draw attention to the author's failure to grasp the rôle of the A.D.M.S., with a division; at the same time his views of field ambulance organisation give food for thought, and may perhaps suggest a theme for a paper by one of our members. This matter is especially important at this time.

After all, the Field Ambulance is a cumbrous unit, and contains more hospital appliances, &c., than are necessary for its true function of rapid evacuation, while the fact that three of them are allotted to a division and occupy nearly a mile of road space is a serious consideration. I would suggest as a substitute for the present field medical units of a division, one organised as a battalion, with more stretchers and less hospital equipment than three field ambulances, and placed under one commanding officer. The ambulance battalion should have its equipment arranged on the principle of its being a collecting unit and temporary treatment depôt, and it should never be immobilised unless on emergency, and then *only in part*, and in that part only which constitutes the treatment depôt. Time will not permit of detail just now, but I have placed on the board a rough sketch of the battalion. There also you will see an "ambulance column," so needed to complete the link with the clearing hospital. I would reduce, as you see, the ambulance wagons now allotted to the field ambulances, and form the surplus into an ambulance column. I would place more ambulance wagons in that column if I had them, but the savings from the reorganisation I have sketched would supply at least the nucleus for an ambulance column. This brings to mind that the R.A.M.C.(T.) are to be congratulated upon their recent acquisition of clearing hospitals, together with the evacuating agencies afforded by voluntary aid detachments, which will link up the field army with the medical units on the lines of communication.

But our society's vision is not confined to tactical problems. There is much in our proceedings of value in

promoting the study of diseases specially affecting the Services and in improving the health of their members. For instance, there are many sanitary problems by the discussion of which we shall be mentally refreshed. It is not unlikely that the question of incineration in the field may receive a practical solution. By a discussion on this subject we may help to push forward what may become an immense sanitary gain in the field, and thereby a most valuable asset to the nation. At the risk of wearying you I should like to make further calls upon our members with a view to producing papers upon other subjects which may bear upon the health of the sailor or the soldier, and would ask those who have studied any problem likely to be of benefit to the Services not to hesitate to bring such before us. I feel sure that they will be welcomed heartily and that discussion will help the authors, while it widens the scope of thought of every individual.

And here I would ask members who may be diffident because they are junior in rank not to permit such false modesty to restrain them from joining in our discussions, and if they have no superlative opinion of their own intelligence, I would remind them that this society is not official. They will lose nothing by making their thoughts known. The words of thinking men of all ages are worth due consideration, and therefore I hope that all who have studied any medical problem, besides those I have touched upon, will express freely any opinions or experiences they feel would give completeness to our discussions. They will add thereby to the value of our deliberations, and extend our scope of usefulness.

HARD *v.* SOFT WATER.

BY JOHN C. THRESH, M.D. VICT., D.SC. LOND.,
MEDICAL OFFICER OF HEALTH OF THE COUNTY OF ESSEX.

IN the annual report for the county of Essex for the year 1910 I gave a series of statistics showing that (1) in the areas supplied with hard water the death-rate is quite as low as, if not actually lower than, that in the areas supplied with a soft or moderately hard water; and that (2) filtered river water, even when the river water impounded is known to be more or less sewage-polluted, is as wholesome as the water from the deep wells and springs in this county. These conclusions were based upon the statistics for one year only. The report proved of such interest that more copies were applied for than I could supply, and the applications were not limited to this country, the subject being one of equal importance in all parts of the world. When the Census returns for 1911 were received and the Registrar-General supplied me with factors for the correction of the death-rates on account of differences in age and sex distribution of the population in every district of the county, I decided to again consider the subject and take a period of five years as the basis for comparison. The results now given, therefore, are much more reliable than those published in 1911, but they support entirely the conclusion at which I then arrived.

The areas taken are exactly the same as before with the exception that in Group IV. I have included the Romford rural district. The reason for this is that it is decidedly urban in character and the great bulk of the population is supplied with the same water as that used in the Romford urban district.

Besides giving the average death-rates for the five years 1907-11 (inclusive) I have also given the death-rates for 1912, all corrected.

GROUP I.
(Hardness of water-supply under 10° per 100,000.)
Soft Water Area.

	Averages for years 1907-11. Population.	Death-rate per 1000.	Year 1912. Population.	Death-rate per 1000.
Burnham	3,150	8·9	3,200	11·5
Leigh-on-Sea ...	7,100	10·1	8,550	10·7
Maldon...	6,100	11·0	6,335	11·5
Shoeburyness ...	4,800	10·3	5,075	8·7
Southend-on-Sea	56,200	11·2	67,280	9·7
Totals and averages	77,350	11·0	90,440	10·0

All the above districts have public supplies derived from deep wells in the Thanet sand or chalk, having a hardness of from 4° to 10°.

GROUP II.
(Hardness of water-supply between 10° and 20°.)
Moderately Hard Water Area.

	Averages for years 1907-11. Population.	Death-rate per 1000.	Year 1912. Population.	Death-rate per 1000.
Braintree	6,100	12·8	6,170	13·3
Brightlingsea ...	4,500	10·7	4,390	12·1
Colchester	41,990	12·1	44,160	10·7
Saffron Walden ...	6,230	9·7	6,350	7·6
Witham	3,470	10·3	3,480	14·0
Wivenhoe	2,400	7·9	2,500	10·4
Totals and averages	64,690	11·5	67,050	10·9

These country towns all derive water from sources similar to Group I., but the Colchester deep well supply is supplemented by water from gravel springs.

GROUP III.
(Hardness of water-supply 20° to 30°.)
Hard Water Area.

	Averages for years 1907-11. Population.	Death-rate per 1000.	Year 1912. Population.	Death-rate per 1000.
Clacton	9,300	12·0	9,850	9·2
Chelmsford ...	17,000	9·2	18,300	8·9
Epping	4,150	9·1	4,300	7·1
Frinton	1,400	8·0	1,570	8·5
Walton	2,150	9·9	2,190	9·9
Harwich	13,200	14·1	13,970	12·9
Halstead	6,200	12·0	6,300	9·0
Totals and averages	53,400	11·2	56,480	9·9

The Clacton supply is from springs, as is also a small proportion of the Chelmsford supply. The remainder derive water from deep wells in the chalk.

GROUP IV.
South Essex Area.—Moderately Hard Water.

	Averages for years 1907-11. Population.	Death-rate per 1000.	Year 1912. Population.	Death-rate per 1000.
Barking	30,770	13·0	32,520	10·6
Brentwood ...	6,500	8·8	6,940	6·2
Grays	15,810	11·0	16,420	10·7
Romford	16,550	10·2	17,600	9·5
Romford Rural ...	23,860	10·5	26,000	9·3
Totals and averages	93,490	11·2	99,480	9·9

These localities are all supplied with chalk water by the South Essex Water Company.

GROUP V.
Metropolitan Water Board Area.—Hard Water.

	Averages for years 1907-11. Population.	Death rate per 1000.	Year 1912. Population.	Death-rate per 1000.
Buckhurst Hill	4,800	10·2	4,900	9·1
Chingford	6,500	8·56	8,680	8·9
East Ham	126,600	12·1	138,450	11·1
Leyton	122,100	10·4	126,700	10·8
Loughton	5,300	9·7	5,500	10·8
Waltham Cross...	6,650	11·35	6,830	10·0
Walthamstow ...	118,500	11·6	128,480	10·4
Wanstead	13,200	8·5	15,700	7·2
Woodford	17,650	9·3	19,070	9·4
Totals and averages	421,300	11·1	454,310	10·6

Summarising the tables we obtain the results as under:—

—	Death-rate per 1000, 1907-11. Average.	Extremes. Maximum.	Extremes. Minimum.	Death-rate per 1000, 1912. Average.	Extremes. Maximum.	Extremes. Minimum.
Soft water area	11·0	11·2	8·9	10·0	11·5	8·7
Moderately hard water areas:						
(*a*) Country towns...	11·5	12·8	7·9	10·9	14·0	7·6
(*b*) South Essex area	11·2	13·0	8·8	9·9	10·7	6·2
Hard water area:						
(*a*) Country towns...	11·2	14·1	8·0	9·9	12·9	7·1
(*b*) Metropolitan	11·1	12·1	8·5	10·6	11·1	7·2

Arranged in order of death-rates we obtain the following interesting results:—

Average for 1907-11.

Soft water area	11·0 per 1000.
Hard water area (metropolitan)	11·1 ,,
,, ,, ,, (country towns)	11·2 ,,
Moderately hard water area (South Essex)	11·2 ,,
,, ,, ,, ,, (country towns)	11·5 ,,

Average for 1912.

Hard water area (country towns)	9·9 per 1000.
Moderately hard water area (South Essex)	9·9 ,,
Soft water area	10·0 ,,
Hard water area (metropolitan)	10·6 ,,
Moderately hard water area (country towns)	10·9 ,,

Naturally there are greater variations in the rates for single years than in the rates for a series of years, but it is obvious that there is no co-relation in either tables between the hardness of the water and the death-rates.

Taking the average for the five years the difference between the death-rate for the area with the softest waters and the area for hardest waters is, in one instance (the metropolitan area), only 0·1 per 1000, and in the other (country towns) only 0·2 per 1000, whilst the moderately hard water areas taken together have a death-rate exceeding that of the hard water areas of from 0·1 to 0·2 per 1000. These differences are so slight that only one conclusion can be deduced—namely, that the character of water-supplies in this county has no effect upon the death-rates.

Incidentally they also confirm the opinion expressed in my previous report that the filtered water from the sewage-polluted rivers, the Thames and the Lea, is as wholesome as the water from our very deep wells and gravel springs. As comparatively little water is taken from springs we may say that the filtered river water is as wholesome as the water from our deep wells, which are celebrated for their great organic purity.

In the report for 1910 I also showed that the incidence of cancer, phthisis, and enteric fever bore no relation to the water-supplies. The statistics for the five years are as under:—

Death-rates from Various Diseases in the Respective Water Areas for the Five Years 1907-11.

	Cancer.	Phthisis.	Enteric fever.
Soft water area	1·0	0·99	0·043
Moderately hard water areas—			
(*a*) Country towns	0·84	0·81	0·021
(*b*) South Essex area	0·86	0·90	0·121
Hard water areas—			
(*a*) Country towns	0·81	0·75	0·04
(*b*) Metropolitan area	0·83	0·81	0·041

The excessive mortality from cancer and phthisis in the soft water area is entirely due to that area including a large and populous seaside resort, and the medical officer of health has shown that fully 25 per cent. of the people who die there from these diseases were actually suffering therefrom when they entered into residence. In fact, they came to reside there in the hope of becoming cured or of prolonging life. When this excess is allowed for there is no excessive incidence in the soft water area.

The tabulated results afford no indication whatever of the hardness or softness of the water having any bearing upon the prevalence of or mortality from any of the three above-mentioned diseases.

It is important to note, however, in connexion with this investigation that the soft waters of Essex differ materially from the soft moorland and upland waters so widely used for the purposes of public supply. These waters contain very little saline matter and often contain so much free carbonic acid as to render them "acid" in character. The soft Essex waters contain no free carbonic acid, and all contain marked quantities of sodium bicarbonate, and may therefore be said to be "alkaline" in character. The inquiry therefore shows that such alkaline waters are perfectly wholesome, as wholesome, in fact, as waters from any other source.

Chelmsford.

Cloake; Price Scholarship in Anatomy and Physiology for students of the Universities of Oxford and Cambridge, £52 10*s.*, L. G. Jacob, of Christ's College, Cambridge; and Science Scholarship, £50, G. Adler.

ARTERIO-VENOUS ANASTOMOSIS FOR IMPENDING GANGRENE;

A REPORT OF 15 CONSECUTIVE CASES WITH ARTERIO-VENOUS ANASTOMOSIS OF THE FEMORAL VESSELS.

BY DR. CHARLES GOODMAN.

THE employment of arterio-venous anastomosis as a clinical procedure has given such widely different results in the hands of different operators, and has led to such a divergence of opinion on the part of these various operators as to the possibility of establishing a reversal of the circulation, that we have attempted the procedure in 15 cases in order to throw some light on the subject; we believe this to be the largest number of cases yet reported from a single source.

In a review of the literature by Halstead and Vaughan, published in January, 1912, they recall that Frank in 1881 was the first man to attempt an arterio-venous anastomosis. Since then many attempts have been made to produce a satisfactory arterio-venous anastomosis in animals, but without success, until in 1902 Carrel reported his perfected technique, and later in 1905 his work with Guthrie. It is the work of Carrel more than that of any other man that has led the surgeon to employ this procedure on the human being. Stich, Touffier, Frouin and Watts, Cottard and Leriche, and others have since then reported successful anastomoses in animals.

The first attempt to perform arterio-venous anastomosis in man was made by San Martin y Satrustegui in 1902, which proved unsuccessful. In 1912 Bernheim, of Johns Hopkins Hospital, reported 6 operations with 4 successes, and in his review of the literature reports and tabulates 52 operations which were performed by 32 operators; of these, only 15 were successful. End-to-end suture according to the method of Carrel was employed 23 times with 8 successes; lateral 12 times with 4 successes; invagination, end of artery into end of vein, twice with 1 success; intubation according to the method of Wieting, 9 times with 2 successes. Bernheim ascribes the large number of failures, first to the large number of operators; secondly, to the fact that a number of the cases were seen late in the course of the disease; and thirdly, that vascular surgery is still in its infancy and offers many technical difficulties.

The possibility of establishing a reversal of the circulation in an extremity has been questioned by Coenen and Wiewerowski, who have presented an array of experimental work against the practicability of the procedure. These views, however, as to the impossibility of the procedure on physiological grounds have been controverted by 15 successful cases.

As to indications, arterio-venous anastomosis is applicable in angeiosclerosis and in arterial thrombus, where the integrity of the limb may be preserved by this means until collateral circulation is established. In regard to methods, end-to-end anastomosis offers the most simple technique and is least likely to be followed by thrombosis.

We have tried the operation in 15 cases, and in this series we noted that the foot, previously cold and cadaverous in appearance, took on a feeling of warmth and a healthy pink colour. The valves of the veins were only a temporary barrier to the course of the blood against the constant pounding of the heart. The pain due to ischæmia was relieved shortly after the operation in all these cases. Strongly presumptive evidence of establishing a reversal of the circulation are the following facts: improvement of colour, increase of warmth of the affected part, relief from pain, filling of the superficial veins, pulsation of veins below site of anastomosis, and return of part threatened with gangrene, or the actual seat of gangrene, to the normal. All writers seem to agree that angeiosclerosis of the lower extremity is an ascending process and leads eventually to gangrene.

A review of our cases shows 6 successes. Several of these cases which promised success required amputation later, but even these had temporary relief from pain. In our experiments upon animals we have tried all the usual methods of anastomosis—end-to-end, side-to-side, end-to-side, intubation, and invagination. In our operations upon human beings we have used the end-to-end method in all

excepting one case, as we found it the simplest in execution and least likely to cause thrombosis. The operation should not be undertaken in the presence of sepsis, advanced or fulminating gangrene. The opportune time for intervention is in the pre-gangrenous stage before mortification has set in, in order to prevent its inception. In non-septic gangrene the improved nutrition of the limb may be hoped for, permitting lower amputation than would otherwise be possible, as is shown in several of our cases.

The utmost delicacy and skill in minute detail must be observed in order to avoid the formation of thrombi; a most rigid asepsis is required throughout the operation, or the object of the operation will be defeated. To reduce the dangers of thrombosis to a minimum we have practised the following precautions. Before the sheath of the vessel is opened the wound must be absolutely freed from, and dried of, any visible signs of blood, and then covered with sterile wound protectors. For this purpose we have used various materials and have found that a thin, black, oriental silk is best suited to this purpose; this material adapts itself to the wound without encroaching upon the operative field, and the colour removes the glaring and trying effect of the open wound upon the eyes of the operator during the more minute details of the operation.

The etiology of the condition which requires this operation is still obscure. With a view of throwing some light on the subject we have enlisted the coöperation of the laboratories of the hospital, and hope in the future to be able to advance some information regarding the disease. We can only hope that the operation will relieve the symptoms, arrest impending gangrene, and save the limb.

As an instance I will cite briefly the first one of our cases.

The patient, a man aged 35, referred to me by Dr. I. Seff, was admitted to Beth Israel Hospital on July 17th, 1912, with endarteritis of the left leg, necrosis of the tip of the great toe, and a large ulcer on the shin. He had similar trouble with his right foot three years ago, for which an amputation below the knee had been performed. According to his history of about one year's standing, he began to suffer pain in the great toe, and later the pain extended to the foot and leg; the pain was particularly acute at night. About six months ago an ulcer appeared on the tip of the great toe; the toe became very much swollen and the entire tip appeared gangrenous. Shortly afterwards an ulcer appeared on the shin. This ulcer and the one on the toe refused to heal.

When the patient was referred to me he was only able to get about with great difficulty. The great toe was swollen to about twice its natural size, was dusky in appearance, and the entire tip appeared necrotic, being extremely painful and tender to the touch. Elevation of the limb was followed by marked blanching of the foot; when the limb was suspended it became very mottled. A shallow ulcer about the size of half a dollar occupied a position on the lower third of the shin. Pulsation could not be felt below Scarpa's triangle in either the popliteal, tibial, or dorsalis pedis. The examination of the urine was negative; the Wassermann reaction was negative. The blood pressure was between 110 and 130. The radiograph did not reveal any calcareous condition of the vessels.

Arterio-venous anastomosis of the femoral vessels was performed on July 22nd. During the first 24 hours the temperature was 100°, and the pulse varied from 80 to 100. I had ordered the head of the bed to be elevated in order to favour the circulation to the limb, but the nurses, in accordance with the habit of raising limbs operated upon, placed several pillows under the leg, nullifying Fowler's position; as a consequence the patient suffered considerable pain. When the limb was placed in the dependent position on the following day the blanched appearance changed to a pink colour and his pain was immediately relieved. On July 24th (the third day) the patient said, "I am more comfortable than I have been for a year." On the fourth day the dressings were opened to inspect the limb, and very much to our surprise and satisfaction we found the ulcer on the shin had taken on a healthy appearance and was healing. At the end of ten days this ulcer, which had resisted all forms of treatment for six months, had completely cicatrised. The swelling on the great toe was diminished and it had taken on a more healthy appearance.

Two weeks after the operation a slight œdema was present and the limb became mottled. On August 10th it was found that the operative wound, which had only apparently healed by primary union, showed evidences of fluctuation, and the introduction of scissors was followed by a gush of clear serous fluid, which must have caused pressure on the vessels, for after it was evacuated the œdema disappeared and the toe began to heal. (This fluid was undoubtedly due to an excessive amount of vaseline which I had used during the operation to protect the vessels.) Three weeks later the toe was entirely healed. The patient was able to get about without discomfort and slept well without the aid of any hypnotics or anodynes.

The ages of our cases varied from 28 to 87 years. There were 13 end-to-end anastomoses, 1 side-to-side, and in 2 of the cases an exposure of the vessel showed that an attempt to anastomose was not warranted on account of the advanced stage of thrombosis of the vessels. In 2 of our cases with gangrene a low amputation seemed to be satisfactory. Of the 8 cases which were failures, including 1 death, 1 was a side-to-side anastomosis, and 3 of the remainder should not have been operated upon on account of the presence of spreading gangrene.

The predisposing factors in the causation of the symptom-complex of the disease and the results so far obtained by operation warrant us in believing that, whenever the operation is undertaken before gangrene has actually set in, the distressing symptoms can be relieved without the sacrifice of the limb to amputation, which heretofore has afforded the only means of relief.

In conclusion, I should like to emphasise that in the absence of infection, even if the lines of the vessels are not evenly approximated, the chink will be filled in with blood clot. As long as this minute blood clot does not project into the lumen of the vessel there is no accretion and it does no harm. Fibrous connective tissue will grow in and organise the blood clot, and the cells which finally reach the surface will become competent as endothelial cells. In other words, a foreign body in blood-vessels, such as a suture, if it is contaminated with ferment, will produce thrombosis. This is exactly what has been attempted in the treatment of aneurysm with electrolysis; the current kills a certain number of blood cells, a certain quantity of ferment is liberated, and accordingly a certain degree of thrombosis is produced. The secret, therefore, of suturing blood-vessels and retaining the normal continuity of the vessels is to render the operative field as free as possible from thrombo-kinase.

New York.

FORMATION OF AN ARTIFICIAL VAGINA BY TRANSPLANTATION OF A PORTION OF THE ILEUM (BALDWIN'S OPERATION);

WITH REMARKS ON THE ETHICAL ASPECT OF THE PROCEDURE.

BY VICTOR BONNEY, M.S., M.D., B.Sc. LOND., F.R.C.S. ENG., M.R.C.P. LOND.,

SURGEON TO THE CHELSEA HOSPITAL FOR WOMEN; ASSISTANT GYNÆCOLOGICAL AND OBSTETRIC SURGEON TO THE MIDDLESEX HOSPITAL; GYNÆCOLOGICAL SURGEON TO THE MILLER GENERAL HOSPITAL, GREENWICH-ROAD, S.E., ETC.

THE surgical treatment of congenital absence of the vagina was extremely unsatisfactory until the American surgeon Baldwin introduced the operation associated with his name, whereby a piece of the ileum transplanted between the bladder and rectum is made to do duty for the missing canal. The method surmounts the chief difficulty that beset all former procedures—namely, the extreme liability for the artificial vagina to contract and prove useless for coitional purposes.

The ethical aspect of the operation provides a wide field for individual opinion, for though its result achieves fitness for the sexual act, sterility must remain in spite of it in the vast majority of cases. Before, however, embarking on this subject I will relate the details of the following case:—

History.—The patient, a girl aged 19 years, was brought to me in 1912. She was stout, well grown, and good looking, and externally all the feminine characteristics were well developed, but she had never menstruated. On account of the amenorrhœa her mother took her to a practitioner, who found complete absence of the vagina. She was sent into a hospital under a gynæcological surgeon, who discountenanced any attempt to remedy the deformity. In consequence of this pronouncement her engagement to a young man was broken off to her great distress. Later she became attached to another young man, but the knowledge of her deformity precluded any idea of marriage. In consequence she became profoundly depressed, and even threatened suicide. The practitioner then sent her to me with a letter strongly urging that if possible something should be done on account of her mental condition.

When I first saw the patient her aspect was that of deep depression. On rectal examination no trace of the uterus could be felt, but both ovaries appeared to be well developed. Though no monthly loss occurred the girl alleged that every month she felt "queer inside," at which times her depression greatly increased. These statements were corroborated by her mother, who also informed me that the girl's sexual feelings were active. The patient was highly intelligent, and she discussed her condition without reserve and with much common sense. The nature of the proposed operation, its limitations, and its risk were fully explained to her and to her parents, and they were given time to decide the matter amongst themselves.

Operation.—As a result of the deliberations of the parties concerned I operated by Baldwin's method in June, 1912. The patient was first placed in the lithotomy position and an incision was made transversely between the meatus and the anus in the situation where the vagina should have been. The urethra and bladder were then separated from the rectum until the peritoneum was reached. A long pair of forceps was then passed upwards to the peritoneum and packed round with gauze. The patient was then placed in the Trendelenburg position and the abdomen was opened in the middle line below the

umbilicus. On exploring I found both ovaries unusually well developed, one of them containing a large recently dehisced follicle. The upper ends of both Müllerian ducts were well formed, a mesosalpinx and the ampullary segment of the tube with the fimbriated extremity being present on either side, but below this they formed a couple of solid cords which after joining with the round ligaments coalesced in the middle line to form a little nodule of tissue just behind the bladder. The terminal portion of the ileum was pulled up and a loop of it chosen about eight inches long where the mesentery was found to be longest; the centre of this loop was about ten inches distant from the ileo-cæcal valve. This loop was then isolated by dividing the bowel at either end of it, closing those ends by suture and restoring the continuity of the intestine by an end-to-end anastomosis. The mesentery was then divided nearly down to its base in a V-shaped manner, so that the isolated segment of ileum merely remained attached by a narrow pedicle. The edges of the mesentery in the continuity of the bowel were brought together by sutures. An assistant now pushed upwards the forceps previously placed in the site of the future vagina, and the little nodule representing the union of the Müllerian ducts and the rest of the tissue over the forceps was divided until they could be pushed into the peritoneal cavity. The isolated loop of ileum was now seized at its middle and pulled downwards into the vaginal site until the part held by the forceps appeared at the vulva. This was the difficult part of the operation. The patient was very fat, of the stout "cobby" build, and the mesentery was short. Moreover, I had isolated an unnecessarily long segment of the gut. It was not until I had shortened this considerably and further divided the mesentery holding it that I was able to get it entirely into position. The peritoneum between the bladder and rectum was now stitched over it and around its mesentery, and the abdominal wound was closed in the usual way. The patient was now placed in the lithotomy position again, and the loop of gut opened at its apex attached by interrupted sutures to the edges of the vulval wound, and lightly packed with gauze.

Result.—The patient made a good recovery. The transplanted loop survived and adhered. For some weeks the daily introduction of glass vaginal dilators was practised, but when it became apparent that no contracture was going to occur this was desisted from.

The local condition now is that of a septate vagina, each limb of which easily admits the finger. I had intended dividing this septum to make a single canal as practised by Baldwin, but when I last saw the patient it had retracted considerably to form a spur, and I therefore decided to leave it alone. If she marries and the spur gives rise to difficulty, it can easily be divided. The canal appears at present to be sufficient for coitus; it is quite free from pain or tenderness. Since the operation the patient has had a watery mucous discharge, yellow in colour and flocculent in appearance, but this is much less than it used to be. The depression has disappeared and she is bright and cheerful.

Those interested in the surgery of congenital absence of the vagina should read Balfour Marshall's admirable review of the subject in the twenty-third volume of the *Journal of Obstetrics and Gynæcology of the British Empire*. He there points out that 15 cases of ileum transplantation have been performed, 11 by Baldwin's method and 4 by that of Mori, which only differs from that of Baldwin in that he uses a single instead of a doubled-up loop of the intestine. All the cases recovered. That a very definite risk attends the operation is, however, not to be denied.

The Ethical Aspect of the Operation.

Turning now to the ethical aspect of the operation certain authorities hold that where childbearing is impossible the procedure, merely to enable coitus to take place, is unjustifiable. I cannot agree with this view, which assumes that the whole object and usefulness of marriage lies in child-bearing. From the racial aspect it is no doubt true, but there are other points of view, the social and the personal, which much more directly influence the individual. That married life may be happy and useful though the wife is obligatorily sterile is common experience. Many women have married after hysterectomy or even double oöphorectomy and yet enjoyed connubial felicity. To a certain proportion of men the fact that their wife cannot have children is no drawback, and though marriage when sterile is a failure as far as regards the race, yet if it brings happiness to the parties concerned it has a very definite social and individual value. To condemn the unfortunate sufferer from this deformity to abandon for ever the natural hope of some day meeting with a companion and support in the battle of life therefore seems to me to be wrong.

On the other hand, it is important to bear in mind that in a certain proportion of these patients the ovaries are undeveloped and the sex sense wanting. Intercourse in the absence of sexual feeling on the part of the woman is very apt to be unsatisfactory even with a normal condition of the parts. Much of the domestic unhappiness that the practitioner sees has it origin in this cause.

In children.—The construction of an artificial vagina should never, therefore, be undertaken until after puberty, for not till then can the fitness of the woman for marrying be estimated or her wishes on the subject consulted.

In unmarried women.—In the larger number of cases of congenital absence of the vagina the girl is brought to the medical man merely because the menses have failed to appear and not because she is suffering either physically or mentally or because marriage is in contemplation. Examination reveals absence of the vagina, a rudimentary condition or complete absence of the uterus, and not infrequently undeveloped ovaries. In my experience these patients are usually conspicuously healthy. Under circumstances such as these no operation is indicated, and, indeed, it will be found that neither the patient nor her parents have any wish for it directly they are satisfied that the absence of the monthly periods is not detrimental to health. The state of affairs ought, however, to be made clear to the mother if possible, and the feasibility of partly overcoming the results of the deformity should marriage be contemplated should be explained to her. For future guidance inquiry should be made as to whether monthly sensations indicative of a "period" (and therefore of functional activity of the ovaries) are noticed by the patient.

There is another class of case, however, in which an unmarried girl is brought to the practitioner, either because (1) the deformity is giving rise to physical suffering owing to retention of menstrual blood in the uterus; (2) marriage is in contemplation; or (3) the knowledge of the deformity is producing mental symptoms.

1. Cases of hæmatometra due to absence of the vagina are very rare, because in most instances the deformity is associated with a non-development or a complete absence of the uterus. There can be no doubt that it would be possible to combine Baldwin's operation with implantation of the uterus into the transplanted segment of ileum, but the procedure has never yet been carried out. An alternative would be to perform Pfannenstiel's operation, in which, after loosening the uterus, the organ is pulled down between the rectum and bladder and the cervix attached to the vulvar mucous membrane. Unfortunately, most of these cases present themselves late and after the retained blood has led to hæmatosalpinx and pelvic peritonitis. Under these conditions an attempt to conserve the uterus would be a mistaken policy, and it would be better to remove it.

2. Where marriage is in contemplation the question of the propriety of the operation requires careful consideration. The character of the patient, the degree to which she desires marriage, her fitness for that state as evidenced by a history of menstrual molimina and the possession of normal sex feelings, should all be inquired into, and the nature of the operation and its limitations and risk must be explained to her. The wishes of the parents must also be consulted, whilst as regards the fiancé it would be best for the medical man himself to explain to him the state of affairs. Where a consensus of opinion in favour of the operation is arrived at by the interested parties the operation is, I think, entirely justifiable.

3. Where the knowledge of the deformity is producing mental symptoms, as in the case I have just recorded, and where after full explanation both the girl and her parents are agreed in desiring the operation, it is, in my opinion, right to perform it.

In married women.—Finally, we come to that class of patient in whom marriage has occurred before the deformity has been recognised, when remedial measures may be sought for: (1) as a sheer act of self-sacrifice on the woman's part, she herself having no sexual desire; or (2) to satisfy the sex sense of both parties.

1. It has been pointed out that a proportion of these patients are sexually deficient, and that under such circumstances the mere provision of a coitional vagina is not likely to be satisfactory from the marital standpoint. Where the patient asks for the operation solely under pressure of her husband's desires, I am of opinion that both he and the surgeon who performs it incur very grave responsibility. Sad cases of this type are sometimes met with. Some years ago a patient was sent to me with the following history. She married without knowing her disability. In spite of it, however, her husband was faithful and they lived together happily. They adopted a little girl as they could

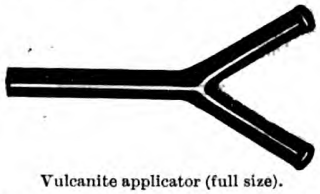
have no children of their own. When this girl grew up illicit relations became established between her and the husband, who deserted his wife to go and live with her adopted daughter. The unfortunate woman believed that rectification of her deformity would be the means of bringing her husband back to her. I, of course, refused to operate. No man whose affection was real and worth keeping would entertain the idea of his wife risking her life solely for his gratification. In the case of such individuals the divorce court provides the proper solution of the difficulty.

2. Where, however, the sex sense of the woman is active, and she desires the operation not merely to satisfy her husband but for her own gratification as well, the case is different, and if after the nature, limitations, and risks of the procedure have been explained to the parties the patient elects to undergo it the surgeon is, I think, entirely justified in performing it.

Devonshire-place, W.

THE USE OF ATROPINE TABLETS FOR THE DETERMINATION OF REFRACTION IN CHILDREN.

BY FRANK MOXON, M.B., B.S. DURH.,
CHIEF CLINICAL ASSISTANT AT THE ROYAL LONDON OPHTHALMIC HOSPITAL.



SINCE first undertaking the treatment of London County Council school children in the special department set apart for these cases at the Royal London Ophthalmic Hospital (Moorfields) in 1910, I have for varying periods made use of tablets of atropine for refraction, and have done so continuously since September, 1912. Ever since then I have been increasingly convinced both of the convenience and of the efficacy of this means of effecting paralysis of accommodation in children. In this short paper it is my wish to give a brief account of my experience with this method in the hope that more will be led to give it a trial.

In most hospitals and school clinics atropine is still ordered for children in refraction cases, either in the form of an ointment or of solution containing from 0·5 per cent. to 1 per cent. of atropine. The directions given for its use in these forms show a diverse and uncertain opinion as to the time necessary to obtain paralysis of accommodation; in the majority of cases ointment or drops are ordered to be used twice, three, or even four times a day, for anything from two, more often from four to seven, or even 14 days before the refraction is estimated. I contend that this practice is quite unnecessary, and a not inconsiderable waste of both time and expense, not only to the parents or guardians, but also to the hospital.

In justification of this custom of giving atropine one is told that it is the most convenient method, and that it is a saving of time. It may be so if the one who orders the ointment or drops does not also do the refraction on the return of the child, but in no other circumstances; and in any case I consider that the fact of the child and guardian having to make a second visit in order to save this time is a matter which in many cases entails no little hardship and expense to those who are least able to afford it. The only other argument advanced in favour of the use of ointment or drops at home for several days is the one that unless atropine is used for several days complete paralysis of accommodation is not obtained in all cases. I have never heard this argument advanced by anyone who has given the tablet method an extended trial, and I am convinced that if more would do so they would be satisfied that it is not only unnecessary, but a positive waste of time to do otherwise. For those who have not tried this method I will give a few details as to the use of the tablets.

First of all I may say that I have always used Messrs. Burroughs Wellcome and Co.'s ophthalmic "tabloid" brand of atropine sulphate, and have always found them highly satisfactory, combining as they do all the merits that an ophthalmic tablet should do—namely, speed in dissolving, accuracy of dosage, reliability in action, non-friability in handling, and a power of keeping for a long period, some that I have used having been in stock for several years. I have used the following strengths—namely, 1/500 grain, 1/200 grain, 1/100 grain—and find that the 1/200 grain tabloid is a satisfactory strength for the purpose. The application of ophthalmic tablets to the eyes is, perhaps, the one part of this method which some will at first find difficult, and I hope that a few words on this will not be out of place.

After the routine external examination of the eyes, including the subjective test for distant and near vision, has been carried out, I take two tablets in the palm of my left hand, pick one up with the forefinger and thumb of my right hand, throw the remaining tablet into the palm of my right hand and pick it up with my left forefinger and thumb. I then ask the child to look up, and at the same time I draw down both lower lids by means of the ring finger of each hand; the tablet is then dropped into the lowest part of each fornix. Should the child tend or attempt to close the upper lids this can be prevented by holding them up with the middle fingers. Immediately the tablets are put in the child is asked to look at you, and at the same moment the lids are released; in this way the tablets are successfully entrapped in the fornices by the lower lids. This will perhaps seem a lengthy dissertation on a simple procedure, but by watching some attempt it I have proved that a few words of advice are helpful. By those who find the use of their fingers not so easy, I have had a double-pronged vulcanite applicator made, which Messrs. Burroughs Wellcome and Co. kindly undertook for me, a sketch of which is here shown.

Vulcanite applicator (full size).

With this applicator a tablet may be attracted to each prong-leaving one hand free with which to draw down the lids at one and the same time.

My reason for desiring to insert the tablets simultaneously, or as near as possible to this, is that if a tablet is put in one eye and that eye is allowed to close before applying the second to the other eye, it will be found that the child feels the first tablet, "screws up the eyes," and makes it extremely difficult to get the second one in. My reason for wishing to entrap the tablet in the lower fornix is that unless this is done the tablet is apt to ride up on to the cornea and thus cause irritation with copious flow of tears before it is fully dissolved, and in this way it may be washed out of the conjunctival sac on to the edge of the lids.

If the procedure is carried out as I have indicated it will be found that the tablet is dissolved almost before the child is aware that there is anything in the eye—in 10 to 20 seconds; very slight smarting is then felt, there is a little pericorneal flush, the pupil dilates fully in from 10 to 15 minutes, and there is a complete paralysis of accommodation in half an hour, at the end of which time I estimate the refraction and order the appropriate lenses. Accommodation is fully restored in from six to eight days. I have now dealt with over 800 children in this manner, and have only once had to apply a second tabloid to get paralysis of accommodation, and in that case it was due to faulty application of the first tabloid, part of which was found on the edge of the lid. It is the rarest thing to find any child cry after having put the tabloids in, and those few who have done so have always shown indications of approaching lacrymation almost before any attempt at touching their eyes had been made. The younger the children the less trouble it seems to cause them, their ages ranging from 4 to 14 years. In applying tablets to a dozen or more children one after the other they are generally all smiling freely after the first one or two have braved the ordeal; select your first two children, and if it is a good selection they will probably laugh over the sensation and the rest will follow suit.

I have more particularly wished to give my experience in this method of atropinisation in order to point out the enormous advantage in time and convenience it has over the home use of ointment or drops in dealing with the refraction of school children in school clinics and suchlike centres where many children are collected together at the same

time. It necessitates only one visit; whereas with the use of ointment or drops it is the invariable experience, no matter what elaborate instructions, written or otherwise, are given, that at least one or two, and often more, out of every dozen return for refraction, either not having used the ointment at all or only partially so. They are then sent back a second time with a further supply of atropine, which although not used the first time yet in some way has mysteriously disappeared. Then, again, a certain number of the cases do not return at all, whereas if the tablets have been used on the first visit there is no chance of escape from refraction at any rate. The use of atropine at home, too, is not such an easy matter, especially when it has to be done three or four times a day for several days. It requires not only experience but time and patience, and how often, as one knows, the home and mother are already saddled with a hundred and one other duties.

One further point to which I would like to draw attention is that I have not yet seen any case, when using these tabloids, present any signs or symptoms of atropine irritation or poisoning. As regards actual cost of material, the tablet method compares very favourably with that of ointment or solution, the hospital price of the tabloids working out at about 6*d.* for a tube of 25, so that 12 cases can be refracted at a cost of a fraction less than $\frac{1}{2}d.$ each. Atropine ointment is supplied in two-drachm chip-boxes at a cost of a $\frac{1}{2}d.$ each, in addition to which a glass rod for application has also to be given, and time spent in the dispensing of the ointment or solution.

London, W.

THE USE OF GELATIN IN MICROSCOPICAL TECHNIQUE.

BY W. JOHNSON, M.D. LOND., M.R.C.P. LOND.,
GULL STUDENT, GUY'S HOSPITAL.

AT the Conference of the Sudwestdeutsche Neurologen und Irrenärzte held in Baden-Baden on May 24th and 25th, Professor Edinger (Frankfort-on-Main) showed several microscopical specimens mounted in gelatin in place of the usual mountant, Canada balsam. As I have had the opportunity, while working in his laboratory, of practising this method, I append details for any who may wish to make use of it. The technique has been developed from suggestions originally made to Professor Edinger by a photographic chemist, Mr. Ralph Liesegang, and has been worked out chiefly from the point of view of utilising it for neurological preparations. It is, however, by no means confined to this particular branch, but can be applied to most pathological work.

Sections may be cut by any of the usual methods—viz., freezing, paraffin, or celloidin. They can then be stained in the ordinary way, and all stains are available with the exception of those which can be extracted from the tissues by immersion in water. This group of exceptions is not large, but, unfortunately, it includes Nissl's method and all others in which the aniline dyes figure. Efforts which we made to fix these dyes in the tissues—as, for instance, by the use of solutions of varying strength of ammonium molybdate—preparatory to placing the sections in water, have proved unsuccessful. Further work may possibly overcome this difficulty.

Having completed the staining process the section is put into water and is now without further treatment ready for mounting in the gelatin solution.

In the preparation of this a few essentials must be noted. Firstly, the solution must be freshly made and the best results are only obtained when the special gelatin, as used for photographic plates, is employed. Of this, 10 grm. are taken and allowed to soak for two hours (preferably overnight) in 100 c.c. of distilled water. When about to be used this solution must be warmed to a temperature of 50° C. by means of a water bath in order to render it sufficiently fluid. It is advisable to filter it beforehand, also at this temperature.

As much of this warm solution is then gently poured on to the slide as can be put on without any overflowing. It is important to pour on as much as possible in order to get a sufficiently thick film of gelatin in the final result. When large sections are being treated it is better to keep the slide on a warm stage, and in the case of frozen or celloidin sections to pour on a thin layer of the gelatin solution first before putting the section in position on the slide. Larger sections still can, with profit, be immersed in the solution for a few minutes beforehand. The preparation is now left exposed to the air, and in the course of a few hours the water evaporates and one is left with the slide covered with a fine transparent film of gelatin in which the section is imbedded. This film behaves in every particular like the gelatin film on a photographic plate. It is intensely hard, resists scratching, and can be packed face to face with other specimens without involving the risk of finding them glued firmly together as is the manner of Canada balsam. Under the microscope a perfectly clear picture is given, and if necessary cedar-wood oil, for oil immersion purposes, can be used.

The great advantage of the method is the economy of time and material which results. There is no tedious transferring from dish to dish for the processes of dehydrating and clearing. Thus alcohol, xylol, Canada balsam, and coverslips are entirely dispensed with, and in addition one does away with the danger of injuring large brain sections which attends too much handling. Apparently specimens will keep indefinitely. Weigert-Pal preparations — for which the method is eminently suitable—have been preserved for three years. Serial sections, which require large slides and coverslips, lend themselves to this manner of mounting. Finally, perhaps, botanists may find here a useful servant. Their chlorophyll specimens, being untreated by alcohol, are able to retain their pigment unaltered, and so can be mounted in the natural state.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF ACCIDENTAL COAL-GAS POISONING, WITH RECOVERY.

BY WALTER ROBERT S. JEFFERISS, M.D., C.M. EDIN., D.P.H.

AS cases of accidental poisoning from coal-gas are not frequently met with in general medical practice, perhaps the following notes of a case may be of some interest to medical men.

On Oct. 4th, 1912, I was asked to go to the relief of a man over 60 years of age who was supposed to be dying. On reaching the house I found the whole place smelling strongly of coal-gas, and on going upstairs to the bedroom, a room of about 11 ft. square, I found the man lying on the bed on his back quite insensible, breathing stertorously, and to all appearance not far from death. There was also one other occupant of the room, a small grey linnet in a cage overhanging the bed, but it, alas, had sung its last song and was lying dead on the floor of its cage. The man's face was livid; his eyes were wide open, the pupils firmly contracted, and the corneal reflex gone. There was not a trace of consciousness left, and the breath smelt strongly of coal-gas. The bowel sphincter was relaxed; the temperature was slightly subnormal, the body being well covered in bed; and the pulse was 68, regular, and moderate in strength. I had the patient brought close to the open window and resorted to artificial respiration, coupled with cold affusion to the head and flicking the body with a wet towel. Consciousness gradually returning, and the patient being now able to swallow, I gave him some hot, strong coffee, a spoonful at a time, and after an hour's efforts he recovered, and I left him in the charge of his relatives. On the next day, after a good natural sleep, the patient seemed quite himself.

The history of the case is as follows. The patient, who lived with his son, not feeling very well on the previous day, had retired to bed somewhat earlier than usual, the gas being lighted to warm the room as there was no fire. The bedstead blocked the fireplace, the door and window were shut, and the gas was allowed to burn

all night, or rather up to a late hour of the night, when the son, as was his custom, turned off the meter on going to his own bed, but omitted to turn off the gas-tap in his father's bedroom. The father, seeming tired, continued to remain in bed, and the relatives considering that he was not "up to much" advised him to rest until after dinner-time, which he agreed to do. After breakfast-time the son had occasion for business requirements to turn on the gas downstairs again, forgetting that the gas-bracket had never been turned off in his father's room. During the afternoon the relatives went upstairs and found the patient as I have described, the room full of gas, and the gas-bracket still on.

This recalls to my recollection an extraordinary case of murder, where the secret opium poisoner used coal-gas to cover up his crime by pretending that his victim (his wife) was dying from accidental poisoning by the escape of coal-gas in her room, and then calling in a medical man, who, at first believing his tale, used similar measures as were used in this case, but finding no success sent for an expert to assist him, and as a result they considered the best thing was to remove the patient to a hospital for further treatment and watching. Their efforts were unsuccessful, and the woman died. A post-mortem examination threw no light on the case, but a small stain on her pillow at her own house was analysed and found to be extract of opium. The poisoner attended his victim's funeral, was shadowed, and then arrested, brought to trial, convicted, and hanged at Edinburgh in 1866. In this case the poisoner had broken through the gas-pipe, which was behind a shutter in the room, and thus allowed the gas to escape, which he thought would mislead the medical men and cover up his crime.

During the past year or two I have met with two or three would-be suicides who have tried to effect their purpose by using coal-gas inhalations, but were rescued by their relatives in time to prevent a fatal termination to their foolish attempts.

Chatham.

NOTE ON A NEW OPERATION FOR FEMORAL HERNIA.

BY G. S. THOMPSON, F.R.C.S. ENG.

I THINK it will be admitted that most, if not all, of the operations for femoral hernia are theoretically if not practically unsound, and therefore leave much to be desired. Simple ligature of the sac here, as opposed to the same proceeding in the inguinal variety, is obviously inadmissible. Muscular obstruction to the canal has not yet readily been effected, as far as I am aware, and its attempt by means of a flap from the pectineus muscle can be only temporary, since the tissue used by being inevitably deprived of its nerve-supply must degenerate into a fibrous mass, to say nothing of the objectionable mutilation. This flap method may or may not form an efficient barrier; at any rate, it cannot be relied on with certitude. Approximation of Poupart's ligament to Cooper's ligament or the pubic bone by suture, staples, or wire is apt to alter detrimentally the anatomical arrangement of the parts, causing, amongst other things, undesirable pressure inwardly and from above on the vessels to the lower extremity, whilst metal bodies in this region are a possible source of danger, to say nothing of the loosening of such things as staples. Of all these processes a modification of one of the last, by means of a loose suture between the two ligaments arranged in the form of a network, and acting like a filigree by provoking infiltration by fibrous tissue, would appear to be the best.

The means I adopt and will now describe involve the use of a specially but easily prepared celluloid filigree shaped so as to fill the triangular femoral hernial space. I have already[1] drawn attention to the value of celluloid in some departments of surgery, and amongst other things indicated the especial value of a perforated celluloid plate rather than silver wires as a general filigree substance for large and suitable hernias. Several rectangular-triangular pieces of thin sheet celluloid of various sizes and the shape of the femoral canal are cut. The short outer side is rendered slightly concave, the long side corresponds in position to Poupart's ligament, while the third side opposes Cooper's ligament. These celluloid triangles are riddled with perforations by a fine punch, and the sharp angles thereof are rounded off. The outer concave border is then turned back at right angles to the remainder, and by means of the thumb-nail the flange thus formed is made to present a concavity at its junction with the rest of the plate. Subsequently this flange will be outermost, resting against the vein, and is formed to eliminate the sharp edge that might otherwise ulcerate into the vein and produce disaster. So much for the filigree.

Regarding the operation, a nearly transverse incision having been made over the saphenous opening, the canal defined, and the sac ligated, the connective tissues in the space are gathered outwards so as to form against the vein a cushion next to which the flange will rest. The femoral triangle limited by Poupart's ligament above, Cooper's ligament and the bone below, and the vein and connective tissue externally, is then clearly and cleanly defined. A suitably sized filigree is next chosen and inserted into this space and will rest against Poupart's ligament above, Gimbernat's ligament internally, the pubic bone below, whilst the flange opposes the vein externally, from which it is separated by the pad of loose connective tissue already referred to. Three temporary catgut fixation stitches are inserted through the perforations at convenient spots, thereby fixing the filigree to the above three ligamentous structures. The operation is thereafter concluded. The femoral canal is now completely obstructed and in a short time following the operation the perforations of the plate get riddled by fibrous tissue, as a result of which the plate becomes covered by, and embedded in, the same and thereby firmly fixed *in situ*. By this means the canal is permanently, thoroughly, and satisfactorily closed without causing pressure on, or injury and improper disturbance to, the parts; and hence an impassable barrier is constituted. Moreover, the vessels cannot be damaged or interfered with by this plan, and I think the method will prove not only the most but quite a satisfactory means, to the exclusion of all others, of coping with this troublesome condition.

Amongst other things, celluloid has the great advantage of being flexible, and consequently of adapting itself to every varying conformation of the part. Boiling is apt to crinkle this substance, and therefore it is preferably sterilised by being inserted in alcohol or some antiseptic for some time preceding its use. Celluloid can be obtained in thicknesses varying from that of the ordinary photographic film to cardboard, but for this part of the body the thinner sheets are desirable as forming a resilient and light yet efficient barrier, consisting ultimately of celluloid and its investment of fibrous tissue, which forms a femoral diaphragm.

The same principle as already utilised may be modified and adopted by using a triangular floss-silk or chromic catgut network filigree; and this would constitute an improvement on the plan of constructing *in situ* a mesh by suture of the ligaments of the part—a manipulation, as a fact, not easy of satisfactory accomplishment. If this modification be preferred or is preferable, several sizes of fine meshed triangles should be constructed and the surplus threads prolonged from each angle and two or more places from the upper and lower sides for purposes of suspension and fixation. The outer side of this kind of filigree, as in the case of the celluloid homologue, would be concave. The free threads will be used for fixing the netted filigree to the ligaments of the femoral triangle. This net filigree will have the same effect as the celluloid plate, provoking, and resulting in, the formation of a fibro-cellular diaphragm superimposed on the artificial septum introduced. As the former would probably be adequate to obstruct the canal, an absorbable material like chromic catgut might be sufficient to meet all requirements, failing which floss-silk would be indicated as the substance of choice—a question, however, which time alone can answer.

Kimberley, South Africa.

TINCTURE OF IODINE AS A HOUSEHOLD REMEDY.

BY EDMUND OWEN, F.R.C.S. Eng.,
CONSULTING SURGEON TO ST. MARY'S HOSPITAL, LONDON.

IN recent years surgeons have learnt that a quick and easy way of rendering a wound or a surface of skin surgically clean is by painting or swabbing it with fresh tincture of iodine. To make the method quite trustworthy, the part should be dry at the time, so that the alcohol of the tincture may carry the iodine into the depths of every pore or crevice.

But the public have not yet been taught that they also might find the tincture a valuable friend and protector; that they ought always to have a small bottle of it close at hand,

and that by its prompt use they might prevent many a cut, prick, or scratch becoming the breeding-place of the dangerous germs of abscess, erysipelas, or even lock-jaw. The first-aid man should certainly carry some of it in his pouch, and the cyclist in his wallet. The gardener ought to have a bottle of it within reach, as the germs of lock-jaw live in the soil in which he works. The groom and the horse-keeper should be made fully aware of its value and importance, for the earth of the stable-yard and of the high-road on which they may be wounded is likely to be teeming with these same germs. The school matron should be ready to apply the tincture to the cut finger, the grazed knee, the barked shin, and the kibed heel, and a small bottle of it should be in every workshop and factory. And in the case of a compound fracture, or other grave wound, a pad of wool or linen dipped in the tincture should be placed directly over it, before the doctor has had the chance of seeing it.

The first-aid teacher and the health lecturer should call particular attention to the value of tincture of iodine, and should urge its use in such circumstances as those suggested in preference to all other antiseptics, and should explain why it should be applied to the dry surface.

Amongst the many advantages of the tincture is this, that it is not poisonous or harmful as carbolic acid is apt to be, and that it can be applied straightway, without preparation and also without fear of doing any damage.

Upper Berkeley-street, W.

Medical Societies.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

A General View of Malingering.

THE thirty-second annual session of this society was opened at the West London Hospital on Oct. 3rd, when Dr. F. S. PALMER was inducted as the new President. The "Keetley Memorial Medal" was presented by the President to his predecessor in office, Dr. G. P. Shuter, to whom a very hearty vote of thanks was accorded.

Dr. PALMER then delivered his presidential address, entitled "A General View of Malingering." The term malingering, derived from the French adjective *malingre*—weakly or sickly—had acquired a special significance and much wider application. The present-day interpretation of the word included the *suppressio veri* as well as the *suggestio falsi*, and the reason probably was that there was no essential difference between the simulation of disease to extort money from an employer and the deliberate concealment of known ill-health to defraud a company or corporation. Formerly it was chiefly encountered in the army and navy, among prisoners, and the inmates of hospitals and workhouses, but recently it had become more general, particularly among industrial workers. Among the influences which promoted malingering was the trend of modern legislation. Since the Workmen's Compensation Act of 1906 came into operation the number of claims had gone up by leaps and bounds, and precisely the same experience was reported from France and Germany, where the accident laws were older than our own. Employers had discovered that it was cheaper to settle claims out of court than to contest them. Although the activities of some speculative lawyers and so-called legal aid societies stirred up strife between employers and employees and encouraged malingering, it was a mistake to suppose that the enormous increase of claims admitted by most of the Approved Societies was due entirely to malingering. The National Insurance Act had opened a new and perilous chapter in history and unlocked the floodgates to the risk of malingering on a scale hitherto unknown. Six months' working of the Act had shown that the sickness claims of women were amazing. The desire to get something back for what had been paid was a human failing. The logical sequence to compulsion was resistance, and that it would take the form of malingering in many instances was a certainty. The psychology of malingering was a complex and interesting study; pecuniary gain was not always the underlying motive, and other influences were often at work, such as idleness and a desire for sympathy or notoriety and resentment. Hitherto, the largest proportion of claims were for the results of accident or injury, and extravagant damages were often demanded from wealthy employers, corporations, or the State. Many persons fit to return to work were restrained from making the attempt when litigation was in the air by the fear that it might prejudice the issue. Introspection, suggestion, repeated medical examinations and consultations with solicitors, according to the psychological law, led to the intensification of symptoms, and so long as these mischievous agencies continued in operation the abnormal mental condition was not likely to improve. Although it was the duty of the profession to discountenance any kind of fraud which came under notice, no doctor was expected to undertake the duties of a detective. If he acted in good faith not much was to be feared, and no sensible medical man would make an accusation of malingering unless he was prepared to bring forward positive evidence in support of the charge. Precipitate action was to be condemned. In doubtful cases it was far better to be deceived than to allow unjust suspicion to fall on the victims of some obscure or depressing disease. The essential feature of malingering was deliberate deceit to gain some desired end. Valetudinarianism occupied a different position. The President then considered the various methods of malingering. Valetudinarianism was of great importance from the medical standpoint. Many of these cases, no doubt, came under the head of unconscious or subconscious malingering, but it also included a considerable proportion of genuine invalids who demanded the utmost sympathy and protection. Surgical cases gave far less trouble than medical ones; there was not much scope for fraud in visible physical injuries. When objective signs were present they could be deciphered on regular lines, but if the complaints were only subjective one had to rely on the none too reliable statements of the claimants. Some of the so-called functional cases deceived the very elect. Before a diagnosis of functional disease could be made organic signs must be eliminated from the field of inquiry. The sufferings of the true neurasthenics were only too sad and genuine, and to brand them with the name of malingerer was both cruel and unjust. Finally the President dealt with the prevention of malingering, and made the following suggestions: (1) the appointment of independent medical referees of wide experience; (2) medical assessors to sit with the arbitrators or county court judges to interpret medical evidence; (3) a system of organised lay inspection and visitation; (4) compulsory detention in hospital of doubtful cases; (5) a time limit to functional illnesses; (6) periodical medical examination of suspected cases by independent practitioners; and (7) some system of registration by which the benefits of claimants from all sources could be made known.

During the evening cases were shown by Mr. N. BISHOP HARMAN, and the meeting closed with a vote of thanks to the President for his interesting and opportune address.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on Oct. 3rd. Dr. David Ross, the new President, delivered an address on Some Mistakes in Prognosis. He urged the advisability of not giving a prognosis on seeing a patient for the first time, although one was often demanded, especially from a consultant. An absolutely hopeless prognosis should seldom be given. He doubted whether the date of demise could be fixed by anyone, illustrating the unwisdom of attempting to do so by a case of heart disease in a woman who was given three weeks to live, yet who on hearing the opinion changed her attendant, and three months later became a weekly attendant at the local theatre for about two years. Prognosis depended on a complete and careful examination leading to a scientific diagnosis. Yet the disease should not alone be considered and weighed, but the body as a whole in which it occurred. In bedridden asthenics death was not infrequently delayed though desired. Conversely, some apparently died merely because death was expected by the patient, the illness being but an excuse for the end. To illustrate recovery from the moribund state a puerperal septicæmia was cited in a young woman to whom no good from vigorous treatment resulted. Then morphia in a moderate dose was hypodermically

injected, and, to the surprise of all, sleep succeeded delirium and a gradual convalescence was followed in due course by five pregnancies. Arthritis due to pyorrhœa alveolaris was not invariably cured by the removal of the cause, but might unexpectedly increase. A case of malignant disease of the base of the bladder, seen by a consultant, in a man aged 70, was given an unfavourable prognosis, yet after treatment by ergot and calcium chloride hæmorrhage and retention of urine gradually ceased. Now, three and a half years after the diagnosis was made by the aid of the cystoscope, the man goes twice weekly to the city on business. Prognosis in pulmonary tuberculosis he considered full of difficulty, quoting a case of a young man who seemed to be dying and so to justify an unfavourable opinion. Yet he speedily improved, and is now, four and a half years from then, in active business. When honestly possible a favourable outlook should always be given because of its therapeutic effect. A bad prognosis by destroying hope and paralysing sustained effort might often bring about its own fulfilment.

MANCHESTER MEDICAL SOCIETY.—A meeting of this society was held on Oct. 1st. Dr. J. J. Graham Brown delivered the opening lecture and took as his subject "Certain Aspects of Hemiplegia." His object was to prove that the movements regained on the paralysed side after hemiplegia were due to the re-assumption by the basal ganglia of functions possessed by them before the development of the phylogenetically recent cortex. He briefly reviewed the history of the cortex from the standpoint of comparative anatomy, tracing it from the ganoid fishes through the reptiles, birds, and lower mammals. He then showed that complete ablation of the cortex in these fishes, reptiles, birds, and lower mammals was followed by little or no effect at all, owing to the fact that in these animals the cortex was of such recent appearance that it had not taken the functions of movement and locomotion from the basal ganglia to any great extent. In man, however, most of these functions had been abrogated to itself by the cerebral cortex, although it was probable that the basal ganglia even in his case retained some of their primitive functions as far as locomotion and perception were concerned. He quoted a case of great interest that had come under his observation in which the patient who had hemianopsia was able to state in which direction an object was moved, the blind side being stimulated, although he was unable to "see" it. Dr. Brown then discussed the theories at present accepted as to the factors at work when movements return to a previously paralysed side. He could not agree with the statement that the homolateral cortex was the agent owing to the fact that movements returned after a double hemiplegia. Neither could he accept the theory that such movements were due to the direct pyramidal tract, since the fibres of this tract almost certainly decussate in the cord before passing to the cells of the anterior horn. Dr. Brown considered that the principal tracts concerned in the conduction of impulses to the paralysed side after hemiplegia were the rubro-spinal and the vestibulo-spinal.

NATIONAL ASSOCIATION FOR THE FEEBLE-MINDED.—In the council chamber of the London Guildhall on Oct. 23rd Field-Marshal Lord Methuen will preside over the annual Conference on After-Care. The Lord Mayor will open the conference at the morning session which commences at 10.45, and a paper by Sir William Chance on the Mental Deficiency Act, 1913, will follow the President's address. At the afternoon session, commencing at 2 o'clock, papers are announced by Mr. F. O. Spensley, senior medical officer at the Darenth Industrial Colony, on Occupations Inside Institutions, and by Mrs. Burgwin on Occupations Outside Institutions. There will be a discussion at each session, and work done by feeble-minded inmates at various homes and institutions will be exhibited during the day. In view of the importance of the question of the mentally defective it is expected that there will be a large gathering representative of public bodies concerned in the administration of the new Act. A report of the proceedings will be issued at the price of 1*s*.

Reviews and Notices of Books.

Surgery, its Principles and Practice. By Various Authors. Edited by WILLIAM WILLIAMS KEEN, M.D., LL.D., Emeritus Professor of the Principles of Surgery and of Clinical Surgery, Jefferson Medical College, Philadelphia. Vol. VI., with 519 illustrations, 22 of them being in colour. London and Philadelphia: W. B. Saunders Company. 1913. Pp. 1177. Price, cloth, 30*s*. net.

THE fifth volume of this "System of Surgery" completed the work, and that volume was published in 1909, but the time that has elapsed since then has witnessed so many advances in surgical theory and practice that the editor felt it was desirable to publish a supplementary volume, in which might be included all the latest facts in surgery. The authors of the articles in the previous volumes were therefore asked to provide the extra material, so as to bring their articles up to date; in addition, a few new sections have been added on intratracheal insufflation, the surgery of the hypophysis or pituitary gland, and the use of salvarsan in syphilis.

From the very nature of the volume as a supplement to the "System of Surgery" it follows that many of the articles are brief and, in fact, even a little scrappy, for only those points which are new are recorded; but this in no wise detracts from the value of the volume, for it is these new points which are of importance. It is somewhat invidious to select from so large a mass of material articles for special mention, but there are some which seem to us particularly valuable. The chapter on shock, by Dr. George Crile, of Cleveland, is a very useful summary of his views on this important matter, and as he has probably done more than any other surgeon to advance our knowledge of this condition, this presentation of his views is likely to prove useful. The chapter on what he has named "anoci-association" is a careful account of his methods of avoiding post-operative shock in all its forms, and will be familiar in its contents to readers of our columns. The article on fractures, by Dr. Daniel Eisendrath, of Chicago, also contains much new material.

The new chapter on the surgery of the hypophysis has been written by Dr. Dean Lewis and Dr. Allen Kanavel, of Chicago; it contains a satisfactory account of the development, the anatomy, and the histology of the gland, and its physiology, at least so far as that is known. The symptomatology connected with the pituitary body and the operative treatment which has been employed for tumours affecting it are detailed, thus forming one of the best accounts of this gland and its diseases that we have seen. Dr. George Emerson Brewer has written on the surgery of the thorax, and as this is a department of surgery in which much recent progress has been made the chapter is long. Mr. Mayo Robson's article on the surgery of the stomach certainly merits special mention, as does also the chapter on the surgery of the intestine by Dr. Weller Van Hook and Dr. Allen Kanavel, of Chicago. We should also like to draw attention to the chapter on plastic surgery by Dr. John B. Roberts, of Philadelphia.

The editor has wisely added a general index to the whole six volumes.

British Rainfall, 1912. By H. R. MILL, D.Sc., Director of the British Rainfall Organisation; assisted by CARLE SALTER. With Maps and Illustrations. London: Edward Stanford. 1913. Pp. 468. Price 10*s*.

THIS invaluable work continues to increase in scope and usefulness, the number of stations at which observations are recorded now amounting to 5272, a net increase of 198 over the figure for 1911. The grouping of stations by counties and river basins throughout the United Kingdom is now complete, and useful maps are supplied in this volume,

clearly indicating the basins and watersheds. The mean rainfall for stations in England in 1912 was 39·31 inches, being 23 per cent. above the average of the 35 years, 1875–1909; in Wales it was 56·19 inches, or 19 per cent. above the average; in Scotland it was 49·01 inches, being 11 per cent. above, and in Ireland 44·06 inches, or 8 per cent. above, the average. Within the last 32 years for which comparisons are available, two only (1882 and 1903) have been wetter than 1912 in England and Wales, or in the British Isles. In 1910, for the first time in 21 years, a wet year immediately followed a wet year, and the succession of two dry years followed by one wet year, that had been the rule in England and Wales from 1839 to 1909, broke down. Dr. Mill points out, nevertheless, that it is significant that the very wet year 1912 "falls into place in the old order, maintaining the tradition that every third year should be wetter than the two preceding." The greatest rainfall in the kingdom occurred on Snowdon (Crib Goch), where 205·17 inches were registered; in England 196·43 inches fell at the Stye, near Scafell Pikes, in Cumberland; in Scotland 178·95 inches fell at Loan, Loch Quoich; and in Ireland 106·60 inches were recorded at Gearahameen in the Gap of Dunloe. The least rainfall, 19·24 inches, was registered at Stifford (Essex). The principal feature of the year was the great rainstorm of August 25th and 26th, extending over a considerable part of East Anglia, where a fall of over 3 inches occurred in Norfolk and Suffolk and Cambridgeshire; in East Norfolk and the adjoining part of Suffolk more than 4 inches fell, while in the neighbourhood of Norwich the fall was over 7 inches, at one point (Brundall) 8·09 inches, and at another (Sprowston) 8·25 inches being recorded in these two days. This is the heaviest rainfall hitherto recorded in the British Isles, that at Seathwaite in 1897 having reached only 8·03 inches. Disastrous floods were the inevitable result, the effects of which on the public health have probably been long-continued and far-reaching. We much regret to hear of the ill-health of Dr. Mill, whose eyesight has been so much affected by the constant strain of this work that he has had to take complete rest for a considerable period. It is also regrettable to learn that, although the expenditure on the organisation amounted to £1521, the receipts only came to £1409, the considerable deficit of £112 having to be met by the honorary director himself. If municipal bodies and sanitary authorities understood the value of this organisation and its important bearing on public health questions, we cannot help thinking that more of them would give their support. Only 19 of these public bodies throughout the country subscribe to the organisation.

Syrian Anatomy, Pathology, and Therapeutics, or "The Syrian Book of Medicines." The Syriac text edited from a rare manuscript, with an English translation by E. A. WALLIS BUDGE, M.A., Litt.D. Vol. I.: Introduction, Syriac Text. Vol. II.: English Translation and Index. Oxford University Press, London, New York, Toronto, Melbourne, and Bombay: Humphrey Milford. 1913. Vol. I., pp. clxxviii.–612; Vol. II., 804. Price 42*s.* net.

THE science and art of medicine owe a heavy debt to Syrian Christianity, theologically known as Nestorianism. For it was Nestorian Christians, whether Arabs or Syrians, who in the great schools of Gundisapor and Bagdad studied and translated into Arabic or Syriac from the sixth to the ninth century A.D. the works of Hippocrates and Galen. Such students were Sergius Rish Aina, Bachtishua, and the Mesues, who were Syrians, but the greatest of the translators was Hunain, a Christian Arab, who was assisted by his nephew Hubaish. The Nestorian Church in its palmy days had an organisation which stretched from Asia Minor to China, and the Nestorian physicians were widely known and valued. We learn from Mandeville that the Great Cham of Tartary had: "Of Phisicyens Cristene 200. And of Leches that ben Cristene he hath 210. And of Leches and Phisicyens that ben Sarrazines 20, but he trusteth more in the Cristene Leches than in the Sarazines." It is almost certain that these "Cristene Leches" were Nestorians. Gundisapor was founded, as its name implies, by Sapor I. (A.D. 240–273), and he imported thither Greek physicians, who in the words of Bar Hebraeus "sowed Hippocratic medicine in the East." Thither, too, after the break up of the great medical Syrian school at Edessa, which was closed by the Emperor Zeno in 489 A.D., came various Nestorian physicians, such as Sergius of Rish Aina, who translated portions of Galen. He died about A.D. 536. The last of the great Syrian physicians was Bar Hebraeus, who died in 1286.

Syriac works on medicine are rare, and Dr. Budge has conferred a great benefit on students of historical medicine in thus laying before them a book which, as he says, is "the most important and most perfect Syrian treatise on anatomy, pathology, and therapeutics known to us." The manuscript which he had copied, and the text of which is reproduced in these volumes, was written, he considers, in the twelfth century. It is unfortunately incomplete, for the first portion commences with Chapter III. and portions in the middle and at the end are also missing. This first portion deals with anatomy, pathology, and therapeutics. The second portion deals with astrological matters, and the third, entitled "The Book of Native Medicines," is a collection of popular recipes and prescriptions evidently drawn up by "physicians" who did not adopt the Hippocratic theories which are the foundation of Section I. Dr. Budge considers that the first two sections were probably originally written in Greek, while the third "may have been written in Arabic, or Persian, or in some Syrian dialect."

Section I. is a series of lectures in which the author, whoever he was, follows the principles laid down by Hippocrates and Galen. The various portions of the body and the diseases which affect them are dealt with seriatim, commencing with the head; the last chapter, which is incomplete, begins with diseases of the kidneys. Numerous personal experiences are quoted in illustration of the principles laid down in the lectures, and the author had evidently seen many dissections performed or had dissected himself, for he constantly refers to anatomical points apparent by dissection. Also, he insists on the value of anatomical knowledge for a right diagnosis and successful treatment. Here is an illustrative case (Vol. II., p. 131): "If therefore a man knoweth from the making of dissections the sources of the nerves which come to each one of the members, this man, I say, can cure so successfully the want of feeling and the want of motion of each one of the members, even as I myself did in the case of a man who fell from a horse, and hurt the upper part of his back, and feeling was paralysed in two of his fingers and the half of a third. I ordered them to put plasters on the place which was injured, and the man was cured in a few days. And with the following fact physicians are not all acquainted that the roots of the nerves which are divided (i.e., radiate) in the skin of the hand, wherefrom cometh the power to feel, are of one kind, and that those which move the muscles are of another." The author of the "Book of Medicines" must have felt an honest pride in this case, for Galen relates an exactly similar case with the exception that his patient had fallen from his chariot and not from a horse. (De Locis Affectis, Lib. I.; see Kuhn's "Edition of Galen," Vol. VIII., p. 56 *et seq.*) It must not be imagined that the author exhibits such sound knowledge as the above in all his lectures, for, as is only natural in the state of

physiological knowledge of that time, he is inclined to treat symptoms rather than causes, of which he was necessarily more or less ignorant. But as regards nervous affections and paralyses, wherein, as we have seen, he applies correctly his anatomical and physiological knowledge, he lays down the canon (p. 143) "if a man is not able to make a diagnosis he will not be able to cure the disease properly." On the whole his lectures are far more scientific than the writings of many physicians of the thirteenth and fourteenth centuries, and there is a singular absence of the loathsome prescriptions which are so prominent a feature of later writers, even of the seventeenth century.

In addition to his translation Dr. Budge has supplied a most interesting introduction, giving a description of the MS., a *précis* of the contents of the three sections, a short historical review of ancient medicine, and a chapter dealing with the author so far as anything can be gathered from his work, which is but little. The date of the "Book of Medicines" must be as late as the second century A.D., as Galen and Sorinus (probably Soranus of Ephesus, 98–138 A.D.) are quoted. But the book is, in the main, Hippocratic, and it is one which every student of the history of medicine should study. It is published under the direction of the Royal Society of English Literature of the United Kingdom.

A Course in Normal Histology: A Guide for Practical Instruction in Histology and Microscopic Anatomy. By RUDOLPH KRAUSE, a.o. Professor of Anatomy at the University of Berlin. Translated from the German by PHILIPP J. R. SCHMAHL, M.D., New York. Part I. London: Rebman, Limited. 1913. Pp. 86. Price 5*s.* net.

THE slim volume before us, containing only 86 pages of text, is devoted to the technique of histological study. It is published separately in order that it may prove of use to others besides students of histology, affording as it does an epitome of microscopical methods.

It opens with an account of the structure and principles of the microscope itself, in which are described the properties of lenses, single and in combination, the methods of illumination adopted in modern microscopes, and the structure of the stand itself. Such terms as achromatic and apochromatic are explained, and the principles of immersion and of the construction of objectives are elucidated. A few words of advice are added as to care of these instruments, of which the cost of one suitable to a beginner is given as 300 to 400 marks (£15 to £20). The next section deals with methods of preserving specimens and with the principles of cutting and staining sections, the various fixatives being enumerated and discussed. The author speaks especially highly of corrosive sublimate, and also favourably of formalin, for this purpose. Among methods of cutting sections a good deal of space is devoted to the freezing microtome, which is evidently a favourite with the author for general purposes. The principles of staining are next set forth, the reader being introduced to mordants and lakes, to progressive and regressive staining, to basic and acid stains, and so forth, and the commoner dyes are enumerated and separately discussed, attention being directed to methods of impregnating tissues with silver or gold and to the mode of injecting organs. Finally, a few pages are devoted to mounting specimens and to measuring and drawing them when finally prepared. Professor Krause rightly lays stress on the importance of every student practising the methods here set forth and not being content to receive specimens ready prepared by a demonstrator, as well as on the value of making drawings of what is observed.

The book forms a very complete guide to histological methods, a large amount of information being compressed into a small compass. The information given is clear, succinct, and accurate. The translation is of only moderate quality, the translator being apparently not quite at home in the English language. For example, we do not usually speak of alcohol "assiduously" attracting water, or of the paraffin method of embedding tissue as the most "aggressive" (does this mean "troublesome"?). Phrases such as "a different colour than ....," "most all will be bleached" (for "almost"), "lest the cement will not adhere," are actually ungrammatical. German compound words like "chlor-calcium," "indig-white" should surely be translated by their English equivalents.

Gynæcological Diagnosis and Pathology. By A. H. F. BARBOUR, M.D. Edin., LL.D. Toronto, F.R.C.P. Edin., Lecturer on Gynæcology in the University of Edinburgh, Gynæcologist to the Edinburgh Royal Infirmary; and B. P. WATSON, M.D., F.R.C.S. Edin., Professor of Obstetrics and Gynæcology in the University of Toronto. With 8 plates and 202 figures. London and Edinburgh: William Green and Sons. 1913. Pp. 220. Price 7*s.* 6*d.* net.

IN this book the authors do not profess to give a complete account of the various conditions that constitute gynæcological pathology; their object has been rather to furnish the student with a method of study. In their opinion gynæcological teaching in the past has suffered from the fact that the student has not been led to the study of actual specimens and the results of microscopical examination. This is, however, by no means the case in all medical schools; there is, at any rate, one school within our knowledge in which systematic instruction in gynæcological pathology has been a prominent feature of the teaching for many years past. If such a defect in the teaching of gynæcology is really common, the fault lies to a large extent with the examiners in the subject, who do not require their candidates to show a knowledge of the macroscopic and microscopic anatomy of gynæcological specimens. A perusal of this book, however, will go far towards putting the student on the right path, and the large number of illustrations should prove of great value in showing him what he is to look for and observe. The book contains a straightforward and clear account of the most important pathological conditions met with by the gynæcologist.

We are glad to see that the authors have given up the old term chronic endometritis; as they point out, this is really not an inflammation of the endometrium, as the name suggests, but includes such conditions as glandular hyperplasia, hyperæmia of the stroma, fibrosis of the stroma, and thickening of the vessels. In view of this fact it is a pity that they still retain the names glandular endometritis and hæmorrhagic endometritis in the legends to the figures they give. This, however, is a minor detail in a very good book which cannot fail to be of great value to the student who honestly studies it. The section dealing with methods of diagnosis, more especially that part of it treating of physical examination, is particularly good, and the tables of the conditions to be found in the vagina and fornices on carrying out a bimanual examination should prove useful to the student.

LIBRARY TABLE.

A Laboratory Manual of Invertebrate Zoology. By GILMAN A. DREW, Ph.D., Assistant Director of the Marine Biological Laboratory, Woods Hole, Massachusetts. Second edition, revised. London and Philadelphia: W. B. Saunders Company. 1913. Pp. 213. Price 6*s.* net.—In reviewing the first edition of this book six years ago we commended the orderly manner of its arrangement and the prominence accorded to the salient points. The present edition contains descriptions for the study of a few forms and a rather simple bibliographical list that were not included in the first edition.

The number of pages has been increased with a corresponding increase of 1*s.* in the price of the book. The manual is a time saver both for teacher and student.

Woman, Marriage and Motherhood. By ELIZABETH SLOAN CHESSER, M.B. London: Cassell and Company. 1913. Pp. 287. Price 6*s.* net.—A volume with such a title naturally arouses interest. The subject is one that might have been discussed in a superficial manner, annoying to the thoughtful public, or with a wealth of learning or detail deterring to all except the expert student of sociology. Dr. Chesser has steered between the two extremes, and has been eminently successful in producing a book which will probably be widely read by the public. She has a sane, healthy outlook on social problems, on the work suitable for women, and she writes in a fluent, bright style which conceals by an appearance of ease much that is the product of wide reading and close thought. Though fearless and outspoken in her description of the danger to the community and to the individual proceeding from prostitution and venereal disease, Dr. Chesser refrains from the screeds encountered in the publications of unbalanced and emotional writers of both sexes. Dr. Chesser claims that she seeks for the sources of wrong and suffering, instead of dealing merely with the effects; hence she seeks for the cure of the social evil in the education of the boy and girl, in the care of the feebleminded, in the prevention of alcoholism, and in the amelioration of conditions of poverty. There is much that is provocative of discussion; there is much with which the social reformer would disagree. There is also much that is but theory and generalisation, but the book is one which can be read and considered with advantage to the home and to the development of the average young woman.

MISCELLANEOUS VOLUMES.

SEVERAL reports of learned societies and reprints of original communications and addresses have reached us during the month, which for reasons of space must be dealt with briefly. In some cases the works appeared originally in our columns.

Volume XVII. of *Studies from the Rockefeller Institute for Medical Research* (New York: Published by the Institute. 1913. Pp. 624) continues its collections of reprints from various scientific and medical journals of work done by the workers in the laboratory. The list is too long to enumerate, but the volume contains, among many valuable and interesting papers, the original communications of Hideyo Noguchi on the Cultivation of the Spirochætæ, and on Treponemata, papers by Simon Flexner and others on Poliomyelitis, by J. B. Murphy on the Transplantability of Malignant Tumours to the Embryos of a Foreign Species, by Alexis Carrel on Permanent Intubation of the Thoracic Aorta and on Pure Cultures of Cells, besides many papers on Physiology and Pharmacology, Chemistry and Biochemistry, and Experimental Biology. There are also many studies from the Hospital of the Rockefeller Institute in regard to Syphilis, Pneumonia, and Heart Diseases and Conditions.——*The Transactions of the Ophthalmological Society of the United Kingdom*, Vol. XXXII. (London: J. and A. Churchill. 1913. Pp. 242. Price 12*s.* 6*d.* net), contain, besides the usual official information, the communications brought before the Society during 1912-13, divided under the following heads: Discussion on Vascular and other Retinal Changes in Association with General Disease, papers by James Taylor, Louis Werner, and George Coats; Diseases of the Eyelids and Conjunctiva, papers by Angus Macnab, M. S. Mayou, C. Killick, and Leslie Paton; Diseases of the Orbit, papers by F. A. Juler, Charles Wray (2); Diseases of the Cornea, papers by Sydney Stephenson, Charles Wray (2), and A. S. Worton; Diseases of the Uveal Tract, papers by Charles Wray (2), Malcolm L. Hepburn (3), and Inglis Taylor; Diseases of the Retina, papers by A. W. Ormond (2), J. B. Lawford, and E. W. Brewerton; Diseases of the Nervous System, papers by James Taylor and Gordon Holmes (2), A. W. Ormond, E. Arthur Donnell, and J. F. Cunningham; Congenital Abnormalities, papers by E. Treacher Collins and A. C. Hudson (jointly), E. Treacher Collins, A. C. Hudson (2); Glaucoma, papers by E. Treacher Collins, Arnold Lawson; Muscles and Refraction, papers by N. Bishop Harman, Ernest E. Maddox, E. W. Brewerton, H. B. Grimsdale and C. J. Hope Gunning.——*The Proceedings of the Chelsea Clinical Society*, Vol. III. (London: *The Medical Magazine*. 1913. Pp. 124), are edited for the council by J. FOSTER PALMER. Besides the usual official information they contain the following papers: Ionisation or Cataphoresis, by Campbell Boyd; the Treatment of Phthisis by the Induction of an Artificial Pneumothorax, by Leonard Colebrook; Diseases of the Skin in Relation to Cardiovascular Disturbances, by David Walsh; the Position of Salvarsan in Therapeutics, by H. Wansey Bayly; the Diagnosis, Prognosis, and Treatment of Neurasthenia, by J. S. Risien Russell; the Nature and Treatment of Neurasthenia, by Gordon Holmes; Puberty and the Menopause in their Bearing on Neurasthenia, by H. Macnaughton-Jones; Neurasthenia in Relation to Internal Secretions, by Leonard Williams; Neurasthenia in Relation to Eye-strain, by Ernest Clarke; the Work of a Tuberculin Dispensary, by Vivian B. Orr; the Use of Tuberculin in Diagnosis and Treatment, by J. H. Halls Dally; and the Preparation and Standardisation of Tuberculins, by Frank Curry. Several of these papers were published in our columns.——The *St. Thomas's Hospital Reports*, Vol. XL. (London: J. and A. Churchill. 1913. Pp. 217. Price 8*s.* 6*d.* net), are edited by Dr. J. J. PERKINS and Mr. C. A. BALLANCE. They contain for the most part an analysis of the practice of the hospital in its various departments. To these is added the Salter Research Report, 1911: On the Action of Certain Drugs, Toxic Bodies, Toxins, and Micro-organisms on the Fragility of the Red Blood Corpuscles of Man and Animals, by W. W. C. Topley, M.B. Cantab., M.R.C.P. Lond.——We have also received Vol. XXXI. of the *Transactions of the Royal Academy of Medicine in Ireland* (Dublin: John Falconer; London: Baillière, Tindall, and Cox; Edinburgh: James Thin; Bristol: John Wright and Co. 1913. Pp. 498), edited by J. ALFRED SCOTT, M.A., M.D., F.R.C.S.I. The Proceedings of this Academy are reported in abstract in our columns.——We have also received bound copies of two lectures: the Bradshaw lecture of Dr. DAVID BRIDGE LEES on the *Diagnosis of Incipient Pulmonary Tuberculosis* (London: H. K. Lewis. Price 5*s.*), published in THE LANCET of Nov. 9th, 1912, and commented on in a leading article in that issue; and the Samuel Hyde Memorial Lectures, by Dr. WILLIAM GORDON, on *The Place of Climatology in Medicine* (London: H. K. Lewis. 1913. Pp. 62. Price 3*s.* 6*d.*), which appeared in our columns on June 14th and 21st, 1913.

In *A Romance of Filey in the Days of Cromwell* (London: John Long, Limited. Pp. 63), "CAN POINT" tells in the iambic tetrameter of Sir Walter Scott the love story of a noble hunchback for the Lady Sylvia. The author is a medical man.——Few medical men have the time, even if they have the mood or capacity, to work out in literary form such visions of the future as Dr. W. WINSLOW HALL foreshadows in *The Peacemaker, a Retrospective Forecast* (London: A. C. Fifield. 1913. Pp. 63. Price 1*s.* net). The book is in the form of a drama in three acts, with intercanticles. The characters represent personifications of the nations, and Dr. Hall reiterates the teachings of self-effacing love inculcated by all the great religions. The ideal set forth is doubtless an eminently desirable one, but we find little evidence that human nature has yet evolved to a sufficiently high plane to render it attainable. The author's vocabulary is sometimes astonishing.

JOURNALS AND MAGAZINES.

L'Hygiène.—The September number of this admirable illustrated journal (MM. Manzi Toyant et Cie., 24 Boulevard des Capucines, Paris) contains a very interesting article by Dr. Horace Bianchon, entitled "Les Dispensaires d'Hygiène Sociale," in which he deplores the ravages of tuberculosis in France, and maintains the absolute necessity of founding dispensaries at once for its prevention. An anonymous author, above the signature "XXX," contributes an interesting description of the epidemic of typhoid fever in Avignon last year. Dr. Linossier writes with a clever blend of the scientific and popular spirit upon what he terms alimentary anaphylaxis; Dr. Maurice de Fleury, Dr. Rochu-Mery, and Dr. Henri Meurisse are among the other contributors. M. Philéas Gilbert contributes the usual article on the cuisine of the month.

The American Journal of Tropical Diseases and Preventive Medicine. New Orleans: The American Journal of Tropical Diseases Company, Limited. Subscription (countries in the Postal Union), $2.50 a year; single copies, 20 cents.—We have received the August and September numbers (Vol. I., Nos. 2 and 3) of this new periodical, edited by Dr. Creighton Wellman, which is the official organ of the American Society of Tropical Medicine. We commented in THE LANCET of August 23rd, p. 579, on an article that appeared in the first number. The numbers now before us consist largely of papers read before the last meeting of the association. In the August number Dr. Victor G. Heiser writes on Further Experiences with Beri-beri in the Philippine Islands; Major Weston P. Chamberlain, U.S. Army Medical Corps, on the Character of the Rice which Prevents Beri-beri and the Manner in which it is Milled; Dr. Creighton Wellman and Dr. C. C. Bass on Polyneuritis Gallinarum caused by Different Foodstuffs, with Special Reference to the Effect of Commercial Rice Coating on Neuritis Production, in which the authors arrive at the final conclusion, as the result of a series of experiments, that "there is more argument against the sale of these common articles of diet, sago, Irish potatoes, and corn starch, than there is against the sale of rice, 'polished' or 'unpolished,' milled or undermilled"; Dr. Carl Lovelace on Peripheral Neuritis in the Amazon Valley; Dr. Bailey K. Ashford on Sprue in Porto Rico and the Results of Treatment by Yellowed Santonin, in which the conclusion is arrived at that santonin does not seem to be superior to a carefully supervised diet, especially a milk diet; and Dr. Juan Guiteras on the White Race and the Tropics. In the September number Major Eugene R. Whitmore, U.S. Army Medical Corps, discusses Free-living and Parasitic Amœbæ and their Relation to Dysentery; Edward O. Jordan, Ph.D., writes on Disease Carriers among School Children (a paper read before the International Congress on School Hygiene, Buffalo, September, 1913); Frederick Knab on Anopheles and Malaria; Dr. Parker Hitchens on Serums and Vaccines in the Prevention and Treatment of Undulant Fever; Dr. Charles C. Bass and Dr. Foster M. Johns on the Cultivation of Malarial Plasmodia (Plasmodium Falciparum) in Vitro in the Blood of a Diabetic without the Addition of Dextrose, in which it is shown that whatever influence dextrose—and this seems to be essential for the cultivation of malarial plasmodia in vitro—has on such cultures may also be produced by the blood sugar of diabetes. A curious case is recorded of a diabetic of three years' standing who last July contracted malaria in Central America. The fever and malaria persisted in this case in spite of sufficient quinine to control the usual case of malaria. The authors suggest that this may have been influenced by the increased amount of dextrose in the blood stream.

Reports and Analytical Records FROM THE LANCET LABORATORY.

(1) RHODALZID; (2) PERUGEN; (3) VESICÆSAN; AND (4) SILVER NITRATE AMPOULES.

(CHEMISCHE FABRIK REISHOLZ, AGENTS, REITMEYER AND CO., 63, CRUTCHED FRIARS, LONDON, E.C.)

1. Rhodalzid is a combination of the thiocyanate group with albumin, which it is suggested replaces the ordinary thiocyanates with therapeutic advantage. The thiocyanates have been used in medical practice for the acute pains of tabes and also in arterio-sclerosis and migraine. They appear, in fact, to have a definite analgesic action, but some observers have stated that the inorganic thiocyanates or sulpho-cyanides have a disturbing effect upon the alimentary tract and rhodalzid is the outcome of these observations. It is, in short, an organic thiocyanate which is said to be free from secondary effects. There is a suggestion that the presence of thiocyanate in the saliva is opposed to caries, and the thiocyanates have been used in caries and stomatitis. Rhodalzid is hygroscopic, the tablets submitted to us being quite soft, but apparently this does not lead to decomposition. Rhodalzid strikes a fine red chestnut colour with ferric salts. The tablets yielded no mineral salts on incineration, so we may conclude that metallic thiocyanates were absent. 2. Perugen is described as a synthetic balsam of Peru. It contains at least 60 per cent. of cinnamein, the normal constituent of the natural product. It is employed in skin diseases depending upon the attack of a parasite. It has been used particularly in scabies and as an antiseptic for wounds. In these applications, however, the natural product has been known to produce disturbance of the kidney function, albumin appearing in the urine. For perugen it is definitely claimed that no such action occurs. 3. Vesicæsan is prepared from the leaves of *uva ursi*, the decoction having had some repute in the treatment of chronic cystitis and vesical catarrh. The leaves contain a definite crystalline principle arbutin which is a glucoside. Vesicæsan is prepared by a special process of extraction by which certain principles which are irritating in the digestive tract or the kidney are eliminated. In addition, vesicæsan is much more acceptable to the palate than the ordinary infusion of bearberry leaves. 4. We have examined the contents of the silver nitrate ampoules, the solution being prepared at a definite strength suitable for application as a prophylactic in ophthalmological practice. The solution being hermetically sealed keeps the desired strength. With the ampoule is supplied a pipette which is plugged loosely at its pointed end with a wad of cotton-wool. The cotton-wool projects somewhat, so that in applying the drops to the eye any contact of the glass edge of the pipette ought to be avoided.

BAD EMS SALTS.

(HERTZ AND CO., 9, MINCING-LANE, LONDON, E.C.)

The salts of the thermal springs at Ems in Hessen-Nassau, Germany, are quite simple in character. They consist principally of sodium bicarbonate and sodium chloride. Other salts occur, but in smaller quantities. Routine treatment at the spa has shown the value of these waters chiefly in catarrhal affections of the mucous membranes. Further, the decided alkalinity of the water probably accounts for the favourable results recorded in rheumatism and urinary disorders. A recent development has taken place at Ems in the installation of a plant which evaporates the waters in vacuo and produces a powder containing the active salts of the natural waters. We have examined a sample of this

powder and find that it contains the chief constituents of the natural water, and in the same proportions. Thus, we found it contained 65·52 per cent. of bicarbonate of soda and 30·42 per cent. of sodium chloride. Magnesium and calcium salts, however, which we found present in the bottle of water, were absent in the powder, probably because these naturally separate on concentration. Their presence, however, is probably not important. It is interesting to note that in the powder the sodium salt occurred as a bicarbonate and not as normal carbonate. The water we examined gave a total mineral residue of 2·94 grammes per litre. This contained 1·75 grammes of carbonate of soda, 1·05 grammes of sodium chloride, 0·13 gramme of calcium carbonate, and 0·068 gramme of magnesium carbonate. We also examined some pastilles which are useful for throat medication. These contained the same salts as the natural water. The water is more effective therapeutically when taken warm. The temperature of the waters at the source is from 83° to 135° F. They are probably radio-active.

PNEUMOSAN.

(THE PNEUMOSAN CHEMISCHE FABRIK, 157, GREAT PORTLAND-STREET, LONDON, W.)

Pneumosan is described as an amyl-thiotrimethylamine compound. The justification of this title appears to be in the fact that amongst its important constituents are methylene blue, which chemically is tetra-methyl thionine hydrochloride, and valeric acid—the oxidation product of amyl alcohol. A third constituent, according to our analysis, is codeine phosphate. The pharmacology of these three constituents is well known. The combination has been tried as an injection in tuberculosis with results which are reported with a confidence that has attracted attention. Reports have appeared which apparently show that in the early stages of tuberculosis the administration of pneumosan is followed by a marked improvement in the condition of the patient. An abatement of fever is recorded, and rise in the opsonic index is said to take place. Reference is made to the value of the valeric acid in the product as influencing a favourable action over the nervous system. The preparation has been analysed and the results have been communicated to us. Our own examination bears out the statements in regard to the principal constituents. We found, for example, that on evaporation of the dark blue fluid a residue was obtained amounting to 1·70 per cent. This on incineration yielded a mineral residue equal to 0·11 per cent. On distillation valeric acid was obtained in the distillate amounting to 0·765 per cent. The same figure was obtained when pneumosan was extracted with ether, the ether taking out apparently the whole of the valeric acid. Further examination showed the presence of codeine combined with phosphoric acid. We found present codeine 1·427 per cent. and phosphoric acid 0·38 per cent. The physician will be helped in his opinion as to the therapeutic claims made for this preparation by a knowledge of its constituents, and we are glad of the opportunity of bringing this information to his notice. A note on pneumosan as a remedy for tuberculosis appeared in our columns of March 30th, 1912, and further reports have appeared in other publications.

ZYMINE PEPTONISING POWDER.

(FAIRCHILD BROS. AND FOSTER, ALBERT CHAMBERS, 64-65, HOLBORN VIADUCT, LONDON, E.C.)

The enzyme products of this firm are well known. There has recently been issued a smaller-sized package of the zymine peptonising powder which readily effects, amongst other things, the peptonisation of milk. The reduced size adds to the convenience in practical use of this agent. We have tried it in regard to the peptonisation of milk and the digestion of starch, and in both cases the results were satisfactory. It rapidly liquefied starch jelly, and ultimately converted it into sugar.

(1) "TABLOID" LYMPHATIC GLAND; (2) "KEPLER" MALT EXTRACT WITH GLYCEROPHOSPHATES; AND (3) "TABLOID" ADJUSTABLE HEAD DRESSING

(MESSRS. BURROUGHS WELLCOME AND CO., SNOW HILL-BUILDINGS, LONDON, E.C.)

1. The tabloid lymphatic gland supplies a convenient means of administering this organo-therapeutic substance. Treatment with lymphatic gland substance is based upon the view that when tonsillar enlargement occurs it is an attempt on the part of nature to increase the lymphoid tissue of the body. The trials in cases of enlarged tonsils and adenoids in children indicate that the snoring has been improved and the tonsils diminished in size. 2. Kepler malt extract is an excellent vehicle for the glycerophosphates which comprise the salts of calcium, magnesium, potassium and sodium. The extract shows a remarkable digestive activity on farinaceous foods, and we had no difficulty in confirming the presence of the glycerophosphates enumerated. 3. We have already described a tabloid adjustable head dressing the convenience of which threatens to replace the old roller bandage. The dressing is now issued in a large size, and therefore supplies a covering in circumstances where the primary dressings require increased accommodation. The numerous useful applications of this head dressing will easily occur to the surgeon. The dressing is compressed, and so far justifies its description of a tabloid. At any rate, when packed it goes easily into the waistcoat pocket.

MALT EXTRACT WITH HÆMOGLOBIN.

(A. WANDER, LIMITED, 1 AND 3, LEONARD-STREET, FINSBURY, LONDON, E.C.)

This is a crystalline preparation comprising the extractives of malt, which include its active digestive principle. It is reinforced with hæmoglobin. We found that on boiling a solution of the preparation a coagulation occurs which carries with it the colouring matter. Viewed with the spectroscope the solution showed the characteristic absorption lines of hæmoglobin. The combination appears to be a useful one in cases where the administration of assimilable iron is indicated. The preparation is palatable and is both a nutrient and hæmatinic.

CYSTOPURIN.

(A. WÜLFING AND CO., 12, CHENIES-STREET, LONDON, W.C.)

Cystopurin is a compound of sodium acetate with hexamethylene-tetramine, the latter now being accepted as a useful bactericide for the urinary tract. The presence of sodium acetate is regarded as assisting the action. Sodium acetate, of course, is changed into the carbonate, and so favours an alkaline condition. The sodium salt is also diuretic. Cystopurin was favourably mentioned in a recent communication to our columns on tuberculosis of the urinary tract, by Mr. J. Howell Evans.[1]

THE AYMARD PATENT MILK STERILISER.

(THE AYMARD PATENT MILK STERILIZER COMPANY, LIMITED, ST. MATTHEW'S WORKS, IPSWICH.)

The principle upon which the effective action of this milk steriliser is based is quite simple. The apparatus consists of a container for the milk, beneath which is a boiler generating steam which travels through a jacketed space around the milk chamber. The milk is therefore not in direct contact with the source of heat; burning is avoided and the taste of the milk is not altered. The temperature obtained is, of course, that of steam at the existing atmospheric pressure, the milk chamber acting as a condenser. Following the directions supplied, confidence may be felt that sterilisation is accomplished by this apparatus.

[1] THE LANCET, August 2nd, 1913, p. 273.

THE LANCET.

LONDON: SATURDAY, OCTOBER 11, 1913.

Education and Examination.

WE publish again this week certain selected addresses delivered at the commencement of the October session in the various medical schools, and among those addresses is one by Sir WILLIAM OSLER which, like every public saying of its distinguished author, merits close attention by those interested in the progress of the medical profession. Sir WILLIAM OSLER, it will be seen, speaks throughout as a frank critic of examinations; he finds overrated both their importance as a test to those who pass them, and their value as machinery for educational purposes. He does not go so far as some have done and suggest that examinations should be abolished, for he is a practical man, and realises that the public, who depend on our professional ministrations, should have a guarantee, itself open to test, that those on whom they rely for medical service are educated up to a certain standard. Examinations form the ready way in which it is possible for those responsible for the medical education of the country to make out a list of practitioners who can be publicly hall-marked as educated, but to allow this is not to allow that in the multiplicity of examinations lies the safety of the public or the elevation of the medical profession to any exalted academic level. We have before now expressed in these columns our entire approval of a motion introduced at the General Medical Council many years ago by that fine and clear thinker, Mr. T. PRIDGIN TEALE, which ran as follows: "That the present system of accumulated examinations and the enormous increase in the number of rejections resulting from it are not only unjust to the student, but damaging to medical education." The figures which Mr. TEALE depended upon in support of this motion indicated that the percentage of rejections at medical examinations had progressively risen from 12·4 in 1861, to 22·2 in 1876, to 34·8 in 1886, and to 41·9 in 1895, while, as Sir WILLIAM OSLER shows in the address which we publish to-day, the five years 1908-12 display a continuation of this significant movement. There can be no two opinions in the matter here—something is wrong when we regard such a percentage of rejections at examinations as the normal outcome of our methods of education.

The statutory period of studentship in medicine in this country is five years, and for practical purposes the time taken by the student to pass his necessary examinations is now seven years. Seven years is a large slab of any man's life, and when those years are taken between such ages as 19 and 26 they cover the flower of adolescence. Stronger in body perhaps, and for certain both richer in learning and more discreet in council, will the young man become, but never again for him can the days have quite the radiancy and flavour of youth. It is no light thing, therefore, that this precious period should in the case of our medical students be too often a period of muddle and mortification. Seven years is not too long a time in which to acquire a working knowledge of the medical profession; but, again, in the absence of any definition as to what constitutes a working knowledge of the medical profession, five years may not be too short a time. It is admitted now on all hands that the medical man must remain a student to the end of his days, and no medical men are happier than those who recognise this fact and who steadily maintain themselves in touch with their profession by attendance at post-graduate classes or by an interchange of views at scientific debates, where personal experiences can be collated and the latest general principles can be adopted with some fulness of knowledge. If the medical man is thus happy in adding to his store of wisdom, why, it may be asked, condole with the medical student because his time spent in adding to his store of wisdom grows longer? The point is that the medical student and the post-graduate student are not in the least comparable persons, while in speaking of the modern medical student we are speaking of a young man for whom it is probable that somewhere in his lengthy career of examinations mortification awaits him. The post-graduate student continues to work, as opportunities serve him, at the practical side of his profession, either in the direction which has for him the chief scientific appeal or that in which he feels that his knowledge particularly requires supplementing. In either case he works *con amore* along lines agreeable to himself, in order to satisfy his conscience, to realise his ideals, and perhaps to make as certain as possible of professional success of a desired sort. The medical student in entering for his first examination may be single-minded in his desire to get forward and to learn more. The rejected student works in no such spirit at all, and a vast number of our students are rejected at least once. In many instances there is with the rejected student an abiding sense of injustice. Of course, we know that very often that sense of injustice is not justified; on the other hand, it must be admitted that the element of chance plays a considerable part in the results of examinations, both pass examinations as well as competitive. In every final examination in medicine we may be fairly certain that some 15 per cent. of the candidates upon re-examination would change their places from rejected to passed, and *vice versâ*. Professor EDGEWORTH'S well-known figures in respect of examinations for the Indian Civil Service, the Home Civil Service, and the Army may be recalled. In these examinations he found in an ingenious manner the element of luck to be such that in any given examination the chances of displacement upon re-examination would amount to one-seventh. Again, there is a feeling, sometimes just and sometimes not, among many students that, although they do not happen to be able to satisfy an examiner with the answer expected, often the question is of the sort that in real life would have had no terrors, inasmuch as in real life either there would be time to clear up the point by consultation of books, or it would not matter in the least whether the point was cleared up.

Students who have grounds for considering that the element of luck is too high, or who feel that an examiner is trying to pose them rather than to ascertain the value of what they know, do not face re-examination with any great relish, and some are beaten before the fight begins.

What is the lesson to be drawn from the admitted fact that our system of examinations, however necessary and however honestly planned, may have a blighting effect upon what is best in the medical education of many of our students, leading too often to a waste of the time of both teacher and taught? Dr. WILLIAM HUNTER, of whose annual report as dean of the Charing Cross Medical School a large portion is published in our present issue, supplies interesting material for an answer, and the answer is coördination. Dr. HUNTER is speaking of London only, and the education of the London medical student is in a critical position, as we await anxiously the new scheme under which the University of London may prove itself a more vital and practical force in the education of our students, making full use of the splendid pathological material of the metropolis and of our unrivalled system of clinical training. But in London there are educated a very large percentage of all English medical students and not a few of those who receive their degrees or diplomas from other educational centres, and if order is introduced into the education of the London medical student we shall have taken a great step towards removing the general conditions of waste and disappointment. What are really necessary at the present moment are patience and adaptability. If with as little friction and delay as possible a new scheme comes into being for the education of the London student possessing the admitted virtues of our present system, but having also a simplicity, economy, and effectiveness which results show to be lacking now, much indeed will have been accomplished. Those who are providing for the country with great zeal and self-sacrifice the national training of our young medical men are not of one mind in detail with regard to a metropolitan university; but as all alike deplore the multiplicity of examinations for which the student has to sit, and the inevitable interference with the smoothness of the curriculum which is caused by the scandalous number of rejections, we believe that differences of opinion, now so acute, may greatly disappear during the work of reconstruction. London should be able to show the way to employ clinical opportunities and pathological resources in the education of the medical student in such a manner as to transform examinations from vexatious and extravagant breakdowns into reasonable halts upon a well-planned journey.

The Rag Flock Act, 1911.

SINCE the measure known as the Rag Flock Act was passed in 1911 experience has shown that unless certain amendments are shortly introduced its salutary intentions may be defeated. The main purpose of the Act was to prevent the use of insanitary material, whether it was made from rags or anything else, in the manufacture of flock for bedding. It was an Act primarily designed to secure clean materials for the mattress on which we sleep, and no one is found to say that this is not an important matter. Judging from the attitude of some magistrates, however, there seems to be a disposition on their part to treat offences under the Act in a trivial way, and this is not in accord with the best traditions. Such an attitude may arise from an ignorance of the real importance of the aim of the Act or because the Act allows a freedom of construction which enables clear cases of offence to escape. It appears, according to the views of at any rate one sanitary authority—viz., the health committee of the corporation of Bradford—that the Act requires strengthening in regard to working definitions. The members of this committee have made, it seems to us, some trenchant suggestions in this direction. They have asked, for example, for a definition of the expression in the Act "flock manufactured from rags" so that it may include flocks whether made directly or indirectly from rags or from some one or more intermediate processes in the conversion of rags into shoddy cloth, as well as flocks developed in the milling, raising, cropping, and other processes which take place after shoddy cloth has been woven. They suggest, also, that the word "rags" shall include all fabrics whatsoever, whether woven or felted, which are admittedly destined for conversion into flock. These recommendations to the Local Government Board, made with the view of securing an amendment of the Act, mean that there are deficiencies in the measure which permit a limited application of its provisions, or which lead to a failure to secure a conviction when an obvious breach of sanitary requirements has been committed.

We learn also that quite recently a practice has arisen which, while satisfying the Act in regard to the statutory limit of chlorine capable of being washed out of rags, may leave in the material undesirable solids and dirt. It may be remembered that the Act states that flock may be passed as having been satisfactorily cleaned or washed which does not yield to distilled water more than 10 milligrammes of chlorine in one litre of wash prepared on well-regulated lines. This test is based, of course, upon the probable presence of soluble impurities in the fabric, but leaves untouched the question of insoluble impurities. The Act would seem, in short, to provide for soaking the material, but not for the thorough washing of it, using that word in the sense of removing all impurities detachable by a washable process. It follows that a mere soaking of flock may fulfil the requirements of the Act in regard, that is, to the chlorine standard (soluble impurities), but the process still leaves the fabric unclean, dirt of all kinds and much objectionable matter not being eliminated by the ordinary process of soaking. The matter is simple in the case of linen. It is obvious that the mere soaking of a shirt in water will not render it clean or presentable, thorough washing is required to take away all evidence of soiling. That is what the Rag Flock Act should ensure in the case of rags intended for bedding if it is to succeed at all under the dignified title of a sanitary reform. On the face of it, it is difficult to suggest how the question of mechanical scouring, the removal of dirt and so forth, can be controlled by laying down a standard unless that control be an actual experimental washing itself. Possibly it may be

practicable to add to the efficiency of the test by requiring, in addition to a limited yield of chlorine, a minimum of colouring material or of attached impurities which are capable of being removed by the ordinary process of washing. The wash water could be examined both for chlorine and suspended impurities, and a minimum allowance imposed in the latter case as well as in the former. It is quite clear that if an efficient washing process has been conducted by the rag flock manufacturer he will have nothing to fear when such a test is carried out upon his material, for thorough washing would exhaust it of those very impurities which the sanitary officer would look for when an examination is made. The whole matter is of the first importance, and we beg to call the attention of all sanitary authorities to the existing situation.

Annotations.

"Ne quid nimis."

RELIGION AND SCIENCE.

UNDER the presidency of the Bishop of Winchester the fifty-third annual Church Congress was held last week at Southampton. The programme challenged criticism by its boldness and novelty. Old questions were set aside and attention was centred upon the work of the Church in the life of to-day, faced as it is with the changes which must inevitably arise in days of progress and development. The deliberations, which were imbued with modern spirit, were concerned with such urgent social questions as the women's movement in its larger aspect, rural betterment, the ethics of property, and (as was appropriate in Southampton, a large port of exit to the great world) the difficult problem of the relation between civilised and backward races. The majority of the speeches on the position of woman indicated the opinion that her first duty was the maintenance and perpetuation of life, that a larger share in social service should be given to her, and that there should be increasing coöperation in public affairs which fall peculiarly within her influence between men and women; little direct allusion was made to the question of female suffrage. The problem of the races, which means much to Great Britain, the world's first colonising force, was discussed from many standpoints. The note of the Congress was that the advances of anthropological science would assist in the foundation of fruitful and successful government. It was felt that the control of backward races by a civilised Power must be "full, complete, and exercised in the light of day," and that although it seemed unwise to force education on people who did not want it, yet all nations and individuals should be given every opportunity for development. The Congress was in many respects a distinctive one and full of hope. It is too early to estimate its real value. But it has done much to establish high ideals, to help forward the cause of social progress and reform, and to forge new and closer links between the Church and the affairs of our collective life. At the Church Congress, as at the recent meeting of the British Association, it became obvious that the antagonism between religion and science is practically in abeyance. Science is, as Sir Oliver Lodge said in his stimulating Presidential Address to the British Association, an affair of the intellect—"it examines everything in the cold light of reason, and that is its strength." But the strength of science is much tried by the vast processes of examination that it now has to carry on, and the faculty of imagination is increasingly employed in these processes. As a consequence a healthy position has been reached in which the faith of the religious man can be respected by earnest scientific workers, while the huge undertakings of science can be supported by religious believers, who see in the stupendous facts revealed to them no contradiction to their beliefs and hopes.

SEPTEMBER AT HOME AND ABROAD.

UNLIKE August, which was cool for the time of year over the greater part of this country, September's temperature was at least equal to the normal, and over a large portion of the kingdom a little above it. In the matter of sunshine, too, it was relatively more generous than the preceding month, although it still fell somewhat short of the average, and was dull when compared with some of the brightest of past Septembers. Like both July and August, its rainfall was below the average in most localities, but not in such a marked degree. In the metropolitan area, as represented by Kew, the mean maximum temperature was 66°, or rather more than a degree above the average, while the mean minimum was 50°, also a trifle more than a degree above. The warmest and brightest weather came during the last week, when, under the influence of a wind current from the south, the sheltered thermometer rose to 70° or above on five days, and only descended to about 55° at night. The first week was the most sunless ever recorded in September, and its remarkable dulness has been seldom surpassed even in the months, November–January. At Kew the first seven days gave a total sunshine of only 8·6 hours, and at Bath 8·3 hours, but when the dense canopy of cloud had once been broken, it never formed again for more than a day, and most of the remainder of the month was fairly bright. The aggregate number of hours at Kew was 127, against an average of 141. As many as 51 hours of the 127 were recorded during the last seven days. Rain fell on 12 days, and yielded a total of 1·73 in., a figure nearly a quarter of an inch below the average. At Bath the mean temperature was slightly higher both during the day and night than at Kew, while the sunshine was practically the same. The rainfall, on the contrary, was much heavier, owing chiefly to a sharp thunderstorm on the 5th. The aggregate figure was as high as 3·17 in., or 0·95 in. above the normal. Further north the mean temperature decreased. At Nottingham the mean maximum and minimum values were 65° and 48·5°, at Harrogate 62° and 49°, and at Buxton 60·5° and 46·6°. Both at Nottingham and Harrogate the total sunshine was about ten hours less than at Kew and Bath, but at Buxton it was about 20 hours less. At Buxton, although rain fell on no less than 18 days, the total fall was no more than 1·83 in., or 2·34 in. below the normal. On the south coast of England the mean maximum temperature differed little from that in London, but the mean minimum was appreciably higher. At Brighton the mean night was nearly 4° warmer than at Kew, and at Bournemouth 2° warmer. The weather was also much more sunny; at Brighton the total sunshine was more than an hour a day above that at Kew. The extreme south-west of England had rather cooler days and milder nights than the rest of southern England, and also more rain and less sunshine, but at Jersey the month was warmer, brighter, and drier than on any part of the mainland of this country. The mean maximum temperature equalled 68° and the mean minimum 55°, while the sun shone during 191 hours, exceeding the average by five hours, and rain fell on only nine days, yielding the small total of 0·65 in. The Continental weather was normally hot and dry in Southern Europe, the temperature rising to between 80° and 90° in Italy and the Spanish Peninsula during the earlier half of the month, and subsequently to between 70° and 80°. In France the heat was not, as a rule, very

great, and the general condition rather variable, with spells of showery, thundery weather, while in the central countries, where the greater part of the period was dry, the decrease in warmth during the latter half was very noticeable. At Paris the mean maximum temperature was 69°, or 3° higher than in London, and at Brussels 68°, but at Berlin it was only 65°. The mean minimum of the nights was nearly the same in all three capitals, being 49° at Brussels and 51° at Berlin and Paris. At Berlin there were only seven days with rain, and the total was no more than 1·66 in., and at Brussels eight days, with a total of 1·49 in. Paris, however, was rather less dry, rain falling on ten days, and giving an aggregate of 1·78 in. Paris was, relatively, more sunny than during August, a total number of hours equal to a little more than six hours daily being registered. In London the figure was little more than four hours daily. The greatest shade heat at Paris was 78° on the 3rd, a figure that was equalled in some parts of London towards the end of the month, but in the French capital the thermometer reached or rose beyond 70° on as many as 14 days. Brussels also had a temperature of 70° or above on 14 days, but at Berlin there were only five readings as high, as in London (Kew). The deluge that accompanied the thunderstorms in the extreme south of France on the 29th was comparatively local, but was extraordinary for the tremendous quantity of water falling in a short time. Over many thousands of acres the amount appears to have varied between 4 in. and 7 in., all of which fell within 24 hours.

THE ETIOLOGY OF RELAPSE IN MALARIAL INFECTIONS.

IT has been asserted by certain experts quite recently that while our knowledge of the malarial parasite, its morphology, mode of transmission, treatment, and prophylaxis is fairly complete, the etiology of relapse in this malady has not yet been satisfactorily determined. This is the more to be regretted since there are good grounds for believing that relapses in malaria lead often to more serious consequences than do primary attacks. The Department of Sanitation of the Isthmian Canal Commission began two years ago an inquiry into the various predisposing causes of relapse in malaria, with the object of verifying or excluding the several hypotheses at present current concerning the etiology of relapse, as well as to ascertain the best methods of prophylaxis and treatment against it. The material thus collected has not yet been fully dealt with, but meanwhile Dr. W. M. James, physician to the Ancon Hospital, has discussed in the *Journal of Infectious Diseases* the various hypotheses put forward. His article is entitled "Notes on the Etiology of Relapse in Malarial Infections," and in it he directs attention more particularly to the two principal hypotheses advanced on this subject, both of them having one factor in common—namely, that relapse is due to the renewal of the asexual cycle of the malarial parasite to a degree when clinical symptoms become observable, and a resistance of the latent parasites, whatever may be their form, to quinine. In summarising his views, Dr. James says that if the hypothesis be accepted that the asexual cycle alone is the cause of relapse, and that under certain conditions there is established a relative immunity against quinine, an explanation is afforded of all the facts associated with the etiology of this condition. Relapse, he goes on to say, is one of the most common factors in malarial infection, and the asexual cycle is that phase of the parasites found to be most frequently connected with the primary infection and relapse. Relapse follows often upon the so-called spontaneous cure of malaria because the asexual cycle in such instances often persists in numbers which can be detected by the thick-film method. Infections treated insufficiently with small doses of quinine will in all probability relapse, because the parasites of the asexual cycle in the spleen and marrow are very slightly, if at all, affected thereby. On the other hand, relapse is less likely to occur when the infection is promptly and vigorously treated, for the older the asexual cycle the more resistant to quinine does it become. When a relapse occurs with manifestation of parasites in the peripheral blood during the administration of quinine by the mouth in sufficient doses, it is evident that there must be faulty absorption of the drug, and that the method of medication ought to be altered. The potential of vitality of the asexual generation is not unlimited, and owing to this, if death does not supervene in the course of a malarial infection, the infection itself will in time die out, but often not until it has done irreparable injury to the patient. It is easier to eradicate an infection in persons who are otherwise in good health, because in these cases the natural protective forces of the body aid the action of quinine. In Dr. James's opinion, the practical importance of the above hypothesis lies in the value it has as a guide to the treatment of malaria. Small doses of quinine even in the mildest infections serve only to render the asexual cycle relatively immune, so that larger doses, which if they had been given early in the attack might have exterminated the parasites, are at a later stage without effect. After numerous experiments with varying doses of quinine Dr. James, in conjunction with his colleague, Dr. W. E. Deeks, of the Ancon Hospital, came to the conclusion that the best method of treating malaria by quinine is to give 45 grains of the sulphate daily, dividing it into three doses, each of 15 grains. By this mode, it is contended, recurrent malaria has been practically banished from among the Americans in the Panama Canal Zone, and to a large extent among the European labourers employed on the Isthmus. But it has to be remembered that the latter are also heavily infected by syphilis, a complication which lessens the efficacy of the routine treatment of malaria until the syphilis itself has been successfully dealt with.

THE NATIONAL GAS CONGRESS AND EXHIBITION.

THERE is an extremely interesting collection of modern gas appliances on view at the National Gas Exhibition at the International Exhibition Halls, Shepherd's Bush, London, which was opened on Oct. 1st by the Lord Mayor of London in the presence of a large gathering of scientific, industrial, and municipal authorities. The exhibition remains open until Nov. 1st. The occasion commemorates the jubilee of the Institution of Gas Engineers and the centenary of public gas-supply. The exhibition reflects the enormous progress that has been made in the methods of gas manufacture and in the appliances employed for utilising gas for power, lighting, and heating purposes. The demonstrations are of an instructive and practical character. An excellent series of popular lectures has been organised which is intended to familiarise the public with the proper and economical use of gas in domestic service. We note with special interest that many of the advances demonstrated give evidence of a regard for hygienic considerations, and this is particularly so in respect of gas stoves. The models now made by the leading gas firms excite our admiration for the excellence of their design, the economy with which they deal with gas as a fuel, and the methods adopted to secure comfortable and healthy warmth for domestic purposes. There is also an incidental display of the numberless by-products obtained in gas manufacture, including ammonia compounds, synthetics, dyes, antiseptics, and so forth. It is interesting to note that medical science owes much of its impetus to the gas industry. The gas

industry supplied, for example, the early antiseptic workers with antiseptics, it furnished also a series of valuable antipyretics and anodynes, while bacteriology owes much of its advance to the aniline dyes which served to bring the organisms of disease into view and into differentiation. The exhibition, therefore, has many points of interest to medical men apart from the great public matters of efficient and healthy lighting and heating.

PERITONSILLAR ABSCESS EXTENDING DOWNWARDS AS FAR AS THE SECOND RING OF THE TRACHEA.

IN the *Boston Medical and Surgical Journal* of August 21st Dr. G. L. Richards has reported a case in which suppuration beginning in a peritonsillar abscess extended downwards as far as the second ring of the trachea. The patient was a well-nourished man, aged 42 years, who had enjoyed good health except for occasional attacks of quinsy. He went to hospital with a history of sore-throat for several days followed by difficulty in breathing and swelling of the entire left side of the face and neck. The left tonsil had been lanced on the previous day and again on the morning of admission but without relief, and the abscess had been enlarging. He was breathing with great difficulty, and there were occasional paroxysms of dyspnœa and coughing. The entire left side of the neck down to the clavicle was swollen and œdematous. Examination of the throat, which was done with difficulty, showed that the tonsil, lateral wall, and the supratonsillar area were intensely swollen. The pulse was 124 and the patient was nearly cyanotic. The skin of the neck was very tense, but no definite fluctuation could be felt. A large peritonsillar abscess was diagnosed. He was seated in a chair, the tongue was depressed, and an incision was made in the supratonsillar fossa. This caused a discharge of pus and a paroxysm of coughing. As this incision was made rather for diagnosis, it was small. An attempt was made to enlarge the opening. A gush of pus escaped, and at the same moment an inspiratory spasm, a cry, and cessation of breathing occurred. He was immediately placed on the operating-table. Unfortunately, no preparations had been made for tracheotomy, and in lifting the patient on to the table the knife was dropped on the floor and lost for the moment. A hurried call for a knife caused the assistant to bring a thin nasal chisel by mistake, and several seconds were lost before a knife was obtained. The head was placed somewhat over the edge of the table, the neck was put on the stretch, and an incision was made at the supposed site of the trachea. Much to his surprise, Dr. Richards entered, not the trachea, but an abscess. The abscess had burrowed downwards to a little below the second ring of the trachea, producing phlegmonous inflammation of the tissues of the neck, and had pushed the trachea well over to the right. While the pus was still flowing the trachea was found and quickly opened. The patient was apparently lifeless, but the pulse was still beating. Artificial respiration was performed, and after a few seconds natural respiration began and a tracheotomy tube was inserted. The peritonsillar abscess and the abscess near the trachea were then widely opened with the aid of the finger. The two were found to communicate. The patient was kept in bed with his feet about a foot higher than his head for the next three or four days, a wick being inserted around the tracheotomy tube. The temperature, which was 101·5° F. on admission, slowly fell. An abundant discharge of pus took place from the mouth and at the side of the tracheotomy tube for a few days. The tracheotomy tube was removed on the eighth day, and the patient was discharged from the hospital cured on the seventeenth day. The case illustrates the danger of allowing a peritonsillar abscess to develop. The pus probably forced its way through the fibres of the superior constrictor of the pharynx, which is in contact with the tonsil, and gained access to the prevertebral fascia. Following this fascia down the neck it came in contact with the larynx and trachea. It was an error to attempt to open such an extensive abscess without being prepared for tracheotomy.

HARD WATER AND OLD AGE.

A FEW months ago we received a communication from a lay correspondent in which he expressed his belief "that the lime in common water has much to do with bringing on old age." In an annotation entitled "Hard Water Fallacies," which appeared in our issue of June 28th, we said that the belief, although fairly common, was fatuous, pointing out that the amount of lime salts consumed in the daily diet was largely in excess of that contained in a daily allowance of the hardest water supplied to the community. In an interesting article published in another column of our present issue under the title of "Hard *versus* Soft Water," Dr. J. C. Thresh gives the results of an extended inquiry which he has made into the question of a possible relation between the hardness of water and the death-rates. His conclusion is that there is no such relation. Taking the averages for the five years (the period of his calculations) the differences between the death-rate for the area with the softest waters and the area for hardest waters is, he points out, in one instance (the metropolitan area) only 0·1 per 1000, and in the other (country towns) only 0·2 per 1000, whilst the moderately hard water areas taken together have a death-rate exceeding that of the hard water areas of from 0·1 to 0·2 per 1000. These differences he regards as so slight that only one conclusion can be deduced—namely, that the natural character of the water-supplies in this country has no effect upon the death-rates. Incidentally they confirm also a previous opinion which he expressed, that the filtered water from the sewage-polluted rivers, the Thames and Lea, is as wholesome as the water from our very deep wells and gravel springs. In 1893 the famous River Pollution Commission reported that "where the chief sanitary conditions prevail with tolerable uniformity, the rate of mortality is practically uninfluenced by the softness or hardness of the water supplied to different towns, and the average of mortality in the different water divisions varies far less than the actual mortality in the different towns of the same division." There is obviously a concordance of observations here which should place at rest the contention that an increased rate of mortality is favoured by hard water. It may be added, however, that a hard water-supply introduces enormous economic inconveniences, amongst which are the furring of the service pipes and fittings and a wastage of soap.

THE TYPE OF BACILLUS IN TUBERCULOSIS OF THE BONES AND JOINTS.

THE view that tuberculosis of the bones and joints is almost exclusively due to the human type of tubercle bacillus is emphasised in the *Deutsche Medizinische Wochenschrift* for Sept. 18th by Dr. B. Möllers, Koch's late assistant. His investigations in 12 cases of tuberculosis involving the bones and joints failed to demonstrate any but the human type of tubercle bacillus. Of the patients examined, three were between the ages of 5 and 16, the rest being older. Pure cultures of the bacilli were obtained in every case; in one case three cultures were obtained at different periods, and in another case two cultures. From the 15 cultures thus obtained 49 rabbits were inoculated with a dose of 10 mgm. each. These subcutaneous inoculations, which were to a certain extent supervised by Koch, conclusively proved,

according to Dr. Möllers, that only the human type of tubercle bacillus was present. He has also collected the observations on this subject made by 15 workers in 163 cases (including the 12 cases already referred to) of tuberculosis of the bones and joints. Of these, only four were associated with the bovine type of bacillus. The remainder were undoubtedly due to the human type. In other words, only 2·45 per cent. of these cases showed the bovine type of bacillus. These conclusions are much at variance with those to which Dr. J. Fraser has been led by his recent examination of 70 cases of tuberculosis of the bones and joints. He found the human type of bacillus in 26 cases and the bovine type in 41, the remaining 3 showing a mixture of the two types. If Dr. Fraser's and the other workers' observations be compared with reference to the ages of the patients, it is seen that in children under 5 years Dr. Fraser finds the human type of bacillus in 27·27 per cent., and the bovine type in 72·72 per cent., while the other workers find the human type in 100 per cent. Between the ages 5 and 16 Dr. Fraser's figures show the human type in 55 per cent. and the bovine type in 45 per cent., while the other workers' figures show the human type in 94·54 per cent. and the bovine type in 5·45 per cent. In adults over 16 Dr. Fraser has not found the bovine type once, while the other workers have found it in 2·2 per cent. Dr. Möllers argues that these differences cannot wholly be explained by the facts that all but three of Dr. Fraser's patients were under the age of 12, and that his material was gathered from a small area comprising Edinburgh and its immediate neighbourhood. He suggests that Dr. Fraser's conclusions should be accepted with reserve so long as the premises on which they are founded are not fully published.

INDUSTRIAL ANTHRAX IN LIVERPOOL.

IN an instructive paper read last year at the International Congress of Hygiene and Demography, and now reprinted, Dr. E. W. Hope and Dr. W. Hanna drew attention to the occurrence of anthrax in Liverpool among a population which does not come under the special provisions of the Factory Act in regard to that disease. These are principally the carters engaged at the docks and quays, who handle imported wool and hides, and the sorters in wool warehouses or skin stores. The Liverpool public health authorities have, in view of its occurrence in this way, declared anthrax to be a notifiable disease. In a period of about eight years 60 cases have arisen in connexion with the importation of these animal products. The majority appear to have been infected in the unloading or carting of hides, either loose or in bales, but 13 were engaged in handling or sorting wools, such as sheep's wool or goats' hair in wool warehouses, while 7 were infected from horsehair or bristles in hair factories. In the latter case the hair was derived from Russian sources; in the case of the hides infection seems to have been brought from all parts of the world, but chiefly from China and the East Indies. The site of invasion in the case of the dock labourers and carters was usually the cheek, but in some instances it appeared elsewhere as a result of the existence of a skin abrasion which became inoculated. The disease in persons of this class is apt to be specially severe, as, unlike the factory workers, they are not familiar with the existence of any risk from anthrax and do not recognise its early signs. The writers do not consider that the danger of anthrax from foreign imported animal products was diminished, but they find that the number of cases in Liverpool shows some tendency to diminish, which may be ascribed to greater care in handling material and to the efforts of the health department to bring to notice the various methods of prevention, short of disinfection, which should be adopted. Protective gauntlets have been provided by shipping firms in many cases, but the difficulty of getting the men to wear them is very great. But much is done by means of cautionary notices prohibiting the carrying of hides on the men's shoulders, use of mechanical means of removal, and like measures. In recent years the earlier recognition of the pustules and prompt treatment in hospital by excision and administration of Sclavo's serum have materially diminished the number of fatal cases.

AUTUMN COURSE OF DEMONSTRATIONS AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

INSTEAD of appointing special guides for visitors to the Museum the Council of the Royal College of Surgeons of England some years ago resolved to institute a series of demonstrations to be given by officers on the Museum staff. During the past five years these demonstrations have been well attended, although the aim of the demonstrators has been to appeal to the research student rather than to the candidates for ordinary examinations in surgery. The present course of demonstrations, which commences on Friday, Oct. 17th, at 5 o'clock, will consist of eight demonstrations, three being given by the conservator, Professor Keith, three by the pathological curator, Mr. Shattock, and two by the odontological curator, Mr. Colyer. The dates and subjects of the demonstrations will be duly noted in our "Diary of the Week." One of the most interesting of the series should be that given by Professor Keith on Oct. 17th, when a peculiar form of defective bone growth—described a few years ago by Porak and Durante, under the name of *Dystrophie periostale*—will be described and discussed. Two complete examples of this curious and instructive condition have been recently added to the Museum. The demonstrations are open free to all medical men and medical students, and cover subjects which are included in higher examinations in surgery.

REINFECTION AND SUPERINFECTION OF PRIMARY SYPHILIS.

THE discovery of the specific parasite, the study of experimental infection in animals, the application of an exact method of diagnosis, and the introduction of a new therapeutic agent are four important factors which have contributed toward revolutionising our old notions of many obscure problems of syphilography. There are two fundamental problems in the question of syphilitic immunity: (1) whether the immunity period coincides, or not, with that of the disease—that is to say, if the subject can be said to be immune only to such an extent, and so long as he is ill, or if, on the contrary, the state of resistance to infection lasts, and if so how long, after cure has taken place—i.e., after the extinction of all the specific parasites in any situation and under any form; (2) whether the immunity period is capable of *extension*—if, that is to say, it must be interpreted as a condition of absolute resistance of the whole organism, or if, on the other hand, a partial resistance must be admitted as against a receptivity of some parts of the organism. Dr. M. Giuseppe has taken up the study of these problems, giving in a recent number of *Il Policlinico*[1] notes of four cases and a critical investigation of the cases of other observers. Such cases fall into two groups, one in which the clinical picture is made up of the complete development of two cycles of specific infection, while the other comprises cases in which one of these two cycles is incomplete and is therefore represented only by a form of primary infection without secondary manifestations. A study of these cases seems to

[1] Il Policlinico, August, 1913. Medical Section, Fasc. 8, p. 337. Roma.

show that there exists a series of clinical types, linked up by transitional forms, in which therapeutic intervention, especially by "606," plays an important part. While it is possible as a rule to arrive at a differential diagnosis between neo-infection and pseudo-primary forms, it is impossible to distinguish accurately between reinfection and super-infection. Two essential and common facts stood out prominently in all the cases examined by the author—first, the intense and typical lymphatic and glandular regional reaction corresponding to manifestations of primary type; and secondly, the delicacy and precision with which the degree of deviation of the complement signalised modifications of the state of the patients' blood serum, *pari passu* with the disappearance or development of the various morbid forms.

FRACTURE OF THE LIP OF THE ACETABULUM.

IN the *Journal de Médecine de Bordeaux* M. J. Guyot has reported a case of one of those minor fractures which have received little attention because they could not be diagnosed before the introduction of radiography. A labourer, aged 41 years, was emptying a pit containing manure when he was surprised by a falling in of the earth and sustained a severe contusion over the left hip. He was thrown down and wounded in the scrotum by the handle of the shovel with which he was working. The wound was sutured by a practitioner and the patient was taken to hospital, where it was dressed, but he was not detained. Abundant suppuration followed, and healing was not completed for 48 days. After the accident he complained of pains shooting from the root of the penis to the left hip and sacro-iliac joints. On examination it was observed that he walked with short steps. When he tried to walk more quickly he was prevented by pain in the hip. There was no deformity or vicious attitude of the limb. Pain was especially felt when he walked with long steps or endeavoured to separate his thighs, even when sitting. The only movement that was limited was rotation outwards of the thigh, which was painful. On movement articular crackling was observed, but this was found in other joints, especially the right hip and both knee-joints. A radiogram clearly showed that a fragment of the lip of the left acetabulum at the upper part had been broken off. There was a region of greater transparency in the neighbourhood which suggested the existence of some osteitis. The outline of the femoral head and of the cotyloid cavity were very clear, as clear as on the opposite side. The patient was examined by an expert and pronounced to be suffering from a permanent incapacity which was estimated at 25 per cent. A fracture of this kind separating a fragment of the acetabulum is rare, and can be discovered only by systematic radiography.

PUBLIC RESPONSIBILITY TOWARDS PUBLIC SERVICE.

THE value of patient, persistent, and probably unobtrusive work in the library as well as in the laboratory still fails of proper recognition at the hands of those in this practical age who constantly use its results without recognising their dependence thereon. Such work supplies the motive power without which the engineer of progress would be unable to propel his vehicle. It is his control and effective direction, it is true, that produce useful work, but the necessary power he must have, and that power is knowledge gained by patient investigation in the laboratory and research in the library. At the recent meeting of the British Association Principal E. H. Griffiths, in his presidential address in the Section on Education, urged the importance of making evident to the working man his indebtedness to the pioneers of science. He instanced the dependence of refrigerating processes on the investigations of Joule and Thomson, of the electric tramcar on the researches of Faraday, of the telegraphist on those of Volta and Wheatstone, of the steelworker on those of Nasmyth and Bessemer, as instances where the workman's means of livelihood were the outcome of purely scientific investigation; and the discoveries of Davy, of Pasteur, of Röntgen, and of Lister, as enabling them to enjoy in security, comfort, and health the fruits of their labours. And so it is also with library work. Elsewhere in this issue will be found a review of the investigations into the British rainfall during 1912. The researches of the British Rainfall Organisation, as our reviewer points out, are of the greatest value for their bearing on public health questions, and should consequently be of interest to municipal bodies and sanitary authorities. It is, therefore, a matter of regret that the subscriptions in support of this most valuable work fall short of the expenditure by £112, which deficit the honorary director, Dr. H. R. Mill, has himself to meet. We feel sure it cannot be necessary to do more than call the attention of the numerous sanitary authorities throughout the kingdom to this fact. A very small individual effort on the part of each of them would remedy this injustice.

THE demonstration by Dr. Hideyo Noguchi, of the Rockefeller Institute for Medical Research, will take place at the Royal Society of Medicine on Monday next, Oct. 13th, at 5.30 P.M. The following will be shown: 1. Pure cultures of various spirochætæ (Treponema pallidum, T. pertenue, T. microdentium, T. macrodentium, T. mucosum, T. calligyrum, and T. refringens). 2. Transmission of syphilis to animals by means of pure cultures of Treponema pallidum. 3. Demonstration of Treponema pallidum in the brain of general paralytics. 4. Transmission of Treponema pallidum from the brain of general paralytics to the rabbit. 5. Production of symptoms and lesions resembling general paralysis in the rabbit by means of an intracerebral or subdural inoculation with Treponema pallidum. 6. Cultural studies of the virus of rabies. These will be demonstrated by the lantern slides and the real objects. Announcements have been made in the lay press for some days of certain discoveries upon which these demonstrations will bear. Dr. Noguchi, as related by our Paris correspondent a fortnight ago, has already given his important demonstration to the Institut Pasteur.

WE have been asked to state that copies of the catalogue of the Museum of the International Congress of Medicine may be obtained from the honorary secretary of the Museum Committee (Mr. H. W. Armit, Ravenhurst, Talbot-road, Wembley), on the payment of the postage (4*d*. per copy).

THE annual dinner of the London School of Tropical Medicine will be held at Prince's Restaurant on Friday, Oct. 24th, under the presidency of Dr. F. M. Sandwith.

GUY'S HOSPITAL MEDICAL AND DENTAL SCHOOLS.—The following Entrance Scholarships and prizes have been awarded:—Senior Science Scholarship for university students (£50): Arthur Gerard East, St. John's College, Oxford. Junior Science Scholarships (£120): Eric Clark Hinde. Preliminary Science Class, Guy's Hospital (£60): Frederick Currer Hiller, St. Paul's School, West Kensington. Entrance Scholarships in Arts (£100): Eric Roland Webb, Dean Close School, Cheltenham; (£50) Gordon Frank Peters. Certificate: Myles Wheeler O'Bryen, Oratory School, Edgbaston. Open Scholarship in Dental Mechanics (£20): Hugh Muir Smith. Scholarship in Dental Mechanics for pupils of Guy's Hospital (£20): George Dee.

HOSPITAL DINNERS.

St. Bartholomew's Hospital.—The annual old students' dinner, which marks the opening of the winter session, was held in the great hall of the hospital on Oct. 1st, under the chairmanship of Dr. Howard H. Tooth, C.M.G., physician to the hospital. Among the large company were Sir Dyce Duckworth, Sir Clifford Allbutt, Professor Howard Marsh, Sir Lauder Brunton, Sir Francis Champneys, Dr. Samuel West, Dr. J. A. Ormerod, and many of the present visiting staff, together with the headmasters of Haileybury, Wellington, and Westminster. The chairman, in proposing the toast of "Prosperity to the Hospital and Medical School," gave a short review of the past year's work, which he said had been one of activity in all departments. The teaching had become more and more organised, and specialists had now been appointed to take charge of each of the special departments, while the systematic lectures had disappeared. The petition for a charter of incorporation of the medical school had been presented early in the year. Referring to the report of the Royal Commission on University Education in London, Dr. Tooth said that these proposals would touch the hospital and medical school at many points and were engaging the earnest attention of the staff. True clinical teaching in England, which brought the student into personal contact with the patient, was the best in the world, and he hoped that that part of our English teaching would be treasured. The effect of the Insurance Act had been to reduce greatly the work of the out-patient and casualty departments, especially on the male side, but there was no evidence of much diminution among the in-patients. The toast was responded to by Mr. G. Acton Davis, acting treasurer of the hospital, who said that during the past year they had had to deal with many difficult problems of administration and finance. Both speakers made feeling references to the premature death of Mr. R. B. Etherington-Smith, and it was announced that the fund to his memory now exceeded £1700. The toast of "The Visitors" was proposed in an admirable speech by Dr. W. P. Herringham, Vice-Chancellor of the University of London, who referred to his aspiration that London University should become to its graduates what Oxford and Cambridge were to theirs, and spoke in praise of the English educational method and tradition. Sir C. Pardey Lukis, Director-General of the Indian Medical Service, and the Rev. Dr. Gow, headmaster of Westminster, responded. Dr. Gow said that he had followed with great interest the controversy on methods of medical education, and he was convinced of the value and importance of the knowledge gained from personal contact between teacher and student and from the *obiter dicta* of the teacher. The health of the chairman was proposed by Sir Anthony A. Bowlby, who spoke in warm terms of Dr. Tooth's personal qualities and of his services to the Officers' Training Corps. The toast was enthusiastically received, and after the chairman had briefly replied an adjournment was made to the library, where a most successful evening was brought to a close.

Guy's Hospital.—The opening of the school year was marked by a dinner in the College dining hall on Oct. 1st, at which the President of the hospital, Mr. Cosmo Bonsor, presided. Among others, the following gentlemen were present: Dr. W. Hale White, Sir W. Arbuthnot Lane, Dr. H. C. Cameron, Dr. Newton Pitt, Sir George Savage, Mr. R. Clement Lucas, Mr. C. J. Symonds, Sir Alfred Fripp, Dr. J. Fawcett, Dr. Herbert French, Mr. R. Wynne Rouw, Mr. Montagu F. Hopson, and Mr. J. Lewin Payne. After the usual loyal toasts the chairman invited the Dean, Dr. Cameron, to present the annual report of the Medical and Dental Schools. In doing so the Dean referred to the extraordinary activity which had been displayed in every department of the medical school throughout the year. Not only had the new pathological department been brought into smooth working order, but the opening of the session was marked by the simultaneous birth of three new departments, those of pharmacology, morbid histology, and chemical pathology, under the direction of Dr. A. J. Clark, Dr. G. W. Nicholson, and Mr. J. H. Ryffel, respectively—departments which were adequately housed, equipped, and staffed. With regard to the future of the medical school, while it would be folly to deny that the present time was a critical one for all medical schools in London, he was able to say this much: that while not a few other schools had sensibly declined, the medical school of Guy's Hospital had at least held its own and even increased its numbers during the past year; and that so far as the financial position of the school was concerned, thanks to the generosity of the governors and other friends, no single scheme for improvement which had won general approval had had to be withdrawn or even postponed for lack of funds. They had set themselves to develop and perfect, so far as possible, the peculiar system of clinical training which was the pride of all the schools of medicine in London, and he thought that the report of the past year's work showed that in this they had been eminently successful. Whatever changes the future had in store for them they had at least been successful in the work which immediately lay to their hand. Mr. Bonsor, in proposing "The Prosperity and Health of the Medical and Dental Schools," spoke of the recent extension of the medical school and the completeness of its equipment both for teaching and research, and said that during all the years in which he had presided over the meetings of the school the one thing which had struck him most had been the absolute determination of the governors and staff alike that no reason whatever should be allowed to stand in the way of securing efficiency in teaching and opportunity for investigation and research, and that no financial sacrifice to attain these ends could be too great. Dr. Hale White, who replied on behalf of the schools, spoke of the enormous debt of gratitude they owed to the long line of treasurers of Guy's Hospital, and especially to Mr. Bonsor, their chairman that evening. Undertaking office at the time of depression both in the hospital and school, he had guided their fortunes to the present unrivalled position. The service of Mr. Bonsor to the schools could never be over-estimated. The work which he had initiated was being admirably carried on by his successor in the office of treasurer, Viscount Goschen, who, to everyone's regret, was unable to be present that evening.

St. George's Hospital.—The annual dinner of the past and present students of St. George's Hospital was held on the evening of Wednesday, Oct. 1st, at Prince's Restaurant, London, Mr. W. Adams Frost, consulting ophthalmic surgeon to the hospital, being in the chair. Sir William Osler, who had delivered the introductory address earlier in the day, which is published in another column of this issue of THE LANCET, was the guest of the evening. After the loyal toasts had been drunk, Mr. Frost in an interesting speech reviewed the circumstances which have led to the impending migration of St. George's Hospital from the site which it has occupied now for 180 years, and reminded his hearers of the interesting fact that amalgamation with the Westminster Hospital would mean the reunion of two long-divided bodies. Mr. West, the treasurer of the hospital, and Dr. R. S. Trevor, dean of the Hospital Medical School, replied, and the latter made a fighting speech on the position of the school, alluding to the brave front which it had presented in the face of many adverse circumstances which were alike unanticipated and uncontrollable. The aim of the school had always been, as Dr. Trevor maintained it should be, to turn out practical physicians and surgeons, adding that "if God made man, the Devil made the bookworm." Dr. Rolleston proposed Sir William Osler as "The Orator of the Day" in a happy speech, in the course of which he read out some of the questions from the famous examination paper on the "System of Medicine" which appeared in 1902 in the pages of *St. Thomas's Hospital Gazette*. Sir William Osler, in reply, explained, and not for the first time, what he really said and what he really meant with regard to the use of the lethal chamber after the age of 60. He amused his hearers by saying that he was only referring to persons of professorial rank, maintaining that professors should retain dignity of person, a charm of manner, and an abundance of hair that was not usually associated with advanced middle age. He pleaded guilty to being a bookworm, despite Dr. Trevor's aphorism, and concluded an excellent speech by the daring suggestion that if a medical degree upon fair terms was not soon provided for London students the students should combine and take the matter into their own hands. He suggested that a strike of students would solve the problem in a very short time. Dr. Drury Pennington proposed "The Past and Present Students of the

School," and the toast was replied to by Mr. Ivor Back and Mr. E. F. W. Grellier. The health of the chairman was neatly proposed by Mr. G. R. Turner.

King's College Hospital.—The anuual dinner of past and present students of this hospital took place on Oct. 2nd at the Waldorf Hotel, under the presidency of Viscount Hambleden, chairman of the hospital and of the medical school. During the afternoon many past students visited the new King's College Hospital at Denmark Hill, and were conducted over the buildings by the Dean and other members of the staff, being afterwards entertained to tea. Among those present at the dinner were Surgeon-General A. W. May (Director-General of the Medical Department of the Navy), Sir C. Pardey Lukis (Director-General of the Indian Medical Service), Mr. A. Boyce Barrow (consulting surgeon to the hospital), Professor Nestor Tirard (senior physician to the hospital), Professor Sir Watson Cheyne (senior surgeon), Sir Ronald Ross, Sir StClair Thomson, Professor W. R. Smith, Professor Ernest White, and Dr. G. E. Shuttleworth. The health of the chairman was proposed by Sir Watson Cheyne, who spoke in warm terms of the exceedingly satisfactory relations which existed between the committee of management and the staff of the hospital. Not until that night had the chair of that dinner been occupied by a layman, but it was unanimously felt that an exception should be made on this memorable occasion, the eve of the opening of their new hospital at Denmark Hill. He was voicing the feelings of all present in expressing the hope that Lord Hambleden would be the chairman of King's College Hospital for very many years to come. Lord Hambleden in his speech explained the reasons which had caused the delay in completing the new hospital. These were largely due to the unfortunate disputes in the labour world during the last few months. He hoped, however, that in a very few weeks the hospital would begin its work, and he was sure the staff would find the building in every way as perfect as it was possible to make it. He desired especially to thank Dr. J. F. W. Silk and the members of the watching committee for the immense amount of time and labour which they had given during the work of building. To this was largely due the perfection of arrangements in the new hospital.

Middlesex Hospital.—The annual dinner of past and present students of Middlesex Hospital was held at the Trocadero Restaurant on Oct. 1st. Sir James Kingston Fowler, K.C.V.O., presided, and a large number of those connected with the hospital and their friends attended. Amongst those present were H.S.H. Prince Alexander of Teck, Sir Alfred Pearce Gould, Dr. W. Pasteur, Sir Squire Bancroft, the Mayor of Marylebone (Mr. J. Penton, jun.), Sir James Collie, and Dr. H. Campbell Thomson, Dean of the School. After the Royal toasts had been honoured, Sir James Fowler proposed the toast of "The Middlesex Hospital and Medical School." He referred to certain matters in the history of the school, especially mentioning the union of the hospital and school. Since the school had been managed by a joint committee, consisting of representatives of the managing body of the hospital and of representatives of the honorary staff and teachers at the school, great success had been obtained. Sir James Fowler referred in terms of deep sympathy to the death of Mr. Andrew Clark, who had been greatly attached to the school. He also spoke in high praise of the excellent work accomplished by Dr. Campbell Thomson as dean of the school. Prince Alexander of Teck, in responding to the toast, said that during the past year separate wards had been allocated for the treatment of patients suffering from skin diseases and for diseases of the eye and ear. In the near future it was hoped that the children's ward would be considerably enlarged, and that the sanitary arrangements of the wards in the south-west wing would be improved. Efforts were being made to put into the hands of the medical staff a sufficient quantity of radium in order that they might test its curative properties to the full. Dr. Campbell Thomson, responding for the school, said that a most satisfactory entry of new students had been obtained. Mr. R. Steer Bowker responded for the past students, and the senior Broderip scholar, Mr. A. O. Gray, for the present students. An excellent musical programme added to a most enjoyable evening.

St. Thomas's Hospital.—The annual dinner of the old students of St. Thomas's Hospital was held at the Hotel Cecil on Oct. 1st, the chair being occupied by Dr. H. P. Hawkins. In proposing the toast of the King, the chairman made reference to the close association between the Sovereign and the hospitals, and while proclaiming the late King Edward as pre-eminent in this respect, remarked that King George was a worthy successor. In proposing the toast of "St. Thomas's Hospital and Medical School," the chairman, after referring briefly to the past, turned his attention to the future, and endeavoured to forecast its trend. This, he said, was an era of change. Of course, there had always been change, and the hospital had adapted itself to such changes. But great and revolutionary changes were now taking place, and these would require considerable adaptation. Referring to the three duties of the hospital—to the patients, to teaching, and to research—he spoke of the necessity for the further organisation of research. The growth of specialism—which was inevitable in consequence of the increase of knowledge to such an extent that no man could compass it all—was such that the day of the general physician was rapidly passing, and soon the specialists would invade the wards, as they had already created for themselves special departments. Moreover, the field of work had now shifted from the wards to the clinical laboratories. He expressed the hope that before they met again a scheme for combined work among the various departments would have taken shape. Mr. J. G. Wainwright, the treasurer, in responding, referred to some of the effects of the Insurance Act. It had reduced the number of genuine out-patients, but had increased the number of casualties; the old-time "chronic" had disappeared. Further, a great many cases were being sent in to the special departments by the panel doctors. The advantage to the hospital in having a tuberculosis department in close contact with it was manifest. The massage department was becoming very large and a baby clinic had been lately established. He referred to the report of the Royal Commission on the University of London, and said that if its recommendations were carried out it would materially interfere with all hospitals. He spoke of a legacy left to the hospital by a former almoner who had recently passed away, which would probably be allocated to the reorganised out-patient department. Referring to the expected and deplored cloud hanging over them on this occasion last year, the retirement of Mr. G. H. Makins, he was glad to inform them that the cloud had lifted and that he was yet to remain a while in active service and coöperate in the reorganisation of the out-patient department. He spoke of Dr. Russell's illness and said that he would be back at his work again by the end of November. Finally, he mentioned that during his treasurership 1194 men had passed through the school and gained their diplomas. Dr. E. Stainer, the dean, also responded, and gave some school statistics. An interesting one was that a party of 30 from St. Thomas's Hospital had helped in the Balkan war. Mr. E. F. White proposed the health of the chairman, who responded. The meeting was a record one, nearly 200 being present, among whom were Surgeon-General Sir Launcelot Gubbins (Director-General, Army Medical Service) and Surgeon-General A. W. May (Director-General, Medical Department, Royal Navy), Alderman Sir Thomas Crosby, M.D., Mr. C. A. Ballance, M.V.O., Dr. F. F. Caiger, Dr. S. M. Copeman, Dr. E. Hopkinson, D.S.O., Dr. S. I. Oddie, coroner for Westminster, and Dr. F. M. Sandwith.

University College Hospital.—The annual dinner for past and present students of University College Hospital Medical School took place at the Café Royal on Oct. 1st. The chair was taken by a distinguished past student of the hospital, Mr. C. J. Bond, of Leicester. The dinner was well attended. The chairman proposed the toast of "The Prosperity of the School" in a felicitous speech full of interesting reminiscences. In his witty reply Dr. G. F. Blacker, the dean, announced the successful state of the school as shown by noteworthy increase in fresh entries and the opening of new departments. Sir Victor Horsley consulting surgeon to the hospital, proposed the health of his friend and fellow-student, the chairman.

Westminster Hospital.—Dr. Purves Stewart took the chair at the annual dinner of the past and present students of the Westminster Hospital Medical School at the Imperial Restaurant, Regent-street, on Oct. 2nd. Proposing the toast of the evening, he referred to the approaching amalgamation of St. George's and Westminster Hospitals.

The principle had been accepted by the governing bodies of both hospitals, which originally were closely related. The newly amalgamated hospitals and schools would have to build a new institution of over 500 beds in some part of London. It had been stipulated that every member of the present staff of both hospitals should retain a position equivalent to that which he now held. Dr. F. de Havilland Hall, in reply, said that the question of name had yet to be settled.

The London Hospital.—The annual old students' dinner was held on Tuesday, Oct. 7th, at the Savoy Hotel, Strand, W.C., when Dr. Wilfred J. Hadley, physician to the hospital, presided over a good assembly. Dr. Hadley, in his speech proposing "Prosperity to the London Hospital," referred to the effect upon the hospital of the National Insurance Act. The reduction in the number of out-patients would mean, he said, a reduction in teaching material for the student; and so serious was this in the matter of tuberculous patients, who were all seeking sanatorium benefits under the Act, that it might be necessary to institute a tuberculosis department.

MEDICINE AND THE LAW.

Mental Deficiency and Provocation as a Defence to a Charge of Murder.

THE Court of Criminal Appeal had to sit recently during the long vacation in order to hear an appeal from a sentence of death passed upon a man named Thomas Alexander at the Central Criminal Court in September. The prisoner, who had received great provocation from his victim, was found guilty of the murder of a woman, Ellen Clarke, and was recommended to mercy by the jury. On the ground that he was mentally deficient an attempt had been made at the trial to induce the judge to put the case to the jury as one of manslaughter, but this he had declined to do; he explained to the jury the law with regard to sanity and insanity, and the jury did not find that the prisoner was insane when he committed the act, but recommended him to mercy, as mentioned above. It was argued on the prisoner's behalf that a thing might be provocation to a man on the border-line of sanity and insanity which could not be treated as a defence in respect of a man perfectly sane. Mr. Justice Darling, who delivered the judgment of the Court of Criminal Appeal, said that it was clear that the jury had held upon the evidence that the man was not insane in the legal sense, although they thought him mentally deficient. All sane persons were not of equal mental capacity, and the verdict meant that the prisoner was below the average mentally, but not across the border-line of sanity, and hence there had been a special verdict. The argument with regard to provocation was ingenious, and one which had not been raised before. If such an argument were allowed to carry weight and a man killed another because he had red hair, the act being done by a person mentally deficient, the judge would have to ask the jury whether the murderer, because he was a person mentally deficient, had sufficient provocation in the fact that his victim had red hair to render the verdict one of manslaughter instead of murder. There was no authority to support such a proposition. Only in very exceptional circumstances could mere words constitute such provocation as would reduce murder to manslaughter. The court must hold that the verdict was a proper one and dismiss the appeal, but it expressed no opinion that would limit the Home Secretary's action in the exercise of the prerogative of the Crown.

LONDON SCHOOL OF TROPICAL MEDICINE.—The winter session opened on Oct. 3rd with 60 students on the books. The additional laboratories, rendered possible by the fund raised by Mr. Austen Chamberlain, are being occupied for the first time. The new course in tropical sanitation and hygiene, open to students who have already attended the ordinary course, will be inaugurated this session, the first lectures being held about Oct. 20th. The increased accommodation for resident students has also been made available, and all the rooms have already been let. The annual dinner will be held at Prince's Restaurant, Piccadilly, W., on Friday, Oct. 24th, under the presidency of Dr. F. M. Sandwith.

Public Health.

REPORTS OF SCHOOL MEDICAL OFFICERS.

City of York.—The report for 1912, signed by Mr. E. M. Smith, school medical officer, and Mr. E. S. Galbraith, assistant school medical officer, is noticeable for the record of work done in the school clinic, which now carries on nearly all the different kinds of work possible to it, and for the presentation of the records of weight and height in conjunction with those of malnutrition. The clinic comprises a "general" department for the supervision of children unfit for school attendance, a treatment department for "minor" ailments, an ophthalmic, and a dental department. There are two whole-time school nurses, five attendance officers, and the whole of the work is well coördinated, the fact that the school medical officer is also medical officer of health materially contributing to this result. The figures for malnutrition show nearly 10 per cent. of children examined to be suffering from this defect; 10 per cent. also "had footgear so defective as to be practically dangerous to the wearer." Also, nearly 10 per cent. are seriously verminous. The "submerged tenth" appears to be a statistical reality. The weights of children are compared with the anthropometric committee's standard, and the total deficiency in weight for the total number of children examined is given as follows:—

—	Children examined.	Deficiency in total weight as compared with anthropometric standard for various age-groups in pounds.	Number of children who would be represented by this weight deficiency.
1910	2,206	9,450	158 { 82 boys. 76 girls.
1911	4,152	14,645	208 { 106 boys. 102 girls.
1912	3,240	11,450	176 { 88 boys. 88 girls.

The total deficiency in weight represented as above in terms of children (calculated as belonging to different age-groups) thus represents the population of a fair-sized school. In other words, the malnutrition in York causes that city to be 542 children short. The question of the special education of such defective children as the feeble-minded and high myopes is receiving attention, and the whole field of medical inspection is gradually being brought under cultivation.

City of Sheffield.—Dr. R. P. Williams's report maintains the high standard of its predecessors and records the continuous growth of the work and the perfecting of the organisation. A valuable feature is the graphic chart of "Facts Disclosed by Medical Inspection," and a diagram giving a bird's-eye view of the agencies coöperating in the very complete school antituberculosis scheme. A proposal is made to combat malnutrition by numerous centres for open-air instruction to which debilitated children would be sent. The record of a special investigation is given in Appendix A with regard to boots and clothing "to determine how far the condition of the child was due to the poverty of the parents and how far to neglect," but unfortunately this requires considerably more explanation than that given to make it of much value to those ouside the district.

City of Carlisle.—Mr. Joseph Beard's report for 1912 calls attention to sanitary defects in schools; the outside conveniences at one infants' school are described as being "in a disgusting and dangerous condition"; and it is very regrettable that any authority should allow such a state of things to continue. Unfortunately, the school medical officer has little or no direct control over the structure or condition of school buildings. A class for "delicate children" is held at Denton Holme, but it is to be hoped the authority will make up its mind to conserve the health of the children who are not yet delicate by providing suitable and sanitary school premises. The cheapness of the open-air school might well be considered if new buildings are required.

County Borough of Bury.—Dr. G. Granville Buckley's report records the beginning of an inspection clinic, one half-day a

week having been set aside for this purpose and 176 cases dealt with. A fair proportion of defective children have been treated, but carious teeth, tuberculous diseases, and various "minor ailments" stand out conspicuously as needing further measures to secure treatment.

Borough of Bootle.—An inspection clinic is held at the town-hall on Monday, Wednesday, and Thursday at 4 P.M., and on Saturday at 10 A.M., and has done useful work. Dr. W. Allen Daley reports that 3966 children were examined in the year, and showed percentages defective: vision, 16·4; four or more unsound teeth, 34·3; and mouth breathers, 14·0. The cost of inspection for the 12 months is given as £489, and the cost per child 9·5*d.* It is noted that owing to the migratory habits of parents of children in Standard II. throughout the borough 38·5 per cent. girls and 31 per cent. boys had not been educated in the corresponding infants' school.

County Borough of Huddersfield.—Dr. S. G. Moore's report suggests the advisability of the wearing of slippers in school, especially in damp weather. The prevalence of dental caries has induced the committee to consider the appointment of a school dentist, and a whole-time officer is to be appointed. The parents attending at the inspections are always handed a note of the height and weight of their offspring, and take the greatest interest in these records. Attention is strongly called to the question of the type used in school books in relation to sight, and the report of the British Association Committee and the comments of the medical officer of the Board of Education are quoted. Children over 9 years should have bold "pica" type and below 9 years "double pica."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns, with populations exceeding 50,000 persons at the last Census and whose aggregate population at the middle of this year is estimated at 17,852,766 persons, 8433 births and 4651 deaths were registered during the week ended Saturday, Oct. 4th. The annual rate of mortality in these towns, which had been 14·5, 14·3, and 14·4 per 1000 in the three preceding weeks, declined to 13·6 per 1000 in the week under notice. During the thirteen weeks of the quarter just ended the mean annual death-rate in these towns averaged 12·7, against a corresponding rate of 11·8 per 1000 in the Metropolis. Among the several towns the death-rate last week ranged from 3·6 in Wimbledon, 6 9 in Bournemouth, 7·0 in Swindon, 7·2 in Ilford, and 7·7 in Hornsey, to 20 8 in Aberdare, 21·9 in Sunderland, 23·2 in Tynemouth, 25·2 in Dewsbury, and 26·5 in Great Yarmouth.

The 4651 deaths from all causes were 285 below the number in the previous week, and included 866 which were referred to the principal epidemic diseases, against numbers declining from 1242 to 1081 in the three preceding weeks. Of these 866 deaths, 730 resulted from infantile diarrhœal diseases, 43 from diphtheria, 32 from whooping-cough, 28 from measles, 19 from enteric fever, and 14 from scarlet fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 2·5, against 3·3 and 3·2 per 1000 in the two preceding weeks. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had been 1104, 983, and 927 in the three preceding weeks, further declined to 730 last week; of this number 142 deaths occurred in London, 45 in Birmingham, 38 in Liverpool, 36 in Manchester, 26 in Hull, 24 in Sheffield, 23 in Leeds, 22 in Stoke-on-Trent, and 19 in West Ham. The deaths referred to diphtheria, which had been 36, 40, and 38 in the three preceding weeks, rose to 43 last week, and included 9 in London, 3 in Portsmouth, 3 in Preston, and 2 each in Cambridge, Great Yarmouth, Bristol, Stoke-on-Trent, Birmingham, Salford, and Rhondda. The fatal cases of whooping-cough, which had risen from 31 to 49 in the four preceding weeks, fell to 32 last week; of this number 5 were recorded in London, 4 in Liverpool, 3 in West Ham, and 2 each in Stoke-on-Trent, Birmingham, Bolton, and Leeds. The deaths attributed to measles, which had been 26, 20, and 31 in the three preceding weeks, declined to 28 last week, and included 5 in London, 5 in Stoke-on-Trent, 3 in Bradford, and 2 each in Dewsbury, Barnsley, and Sheffield. The deaths referred to enteric fever, which had been 10, 13, and 17 in the three preceding weeks, further rose to 19 last week, of which 4 occurred in London and 3 in Stoke-on-Trent. The fatal cases of scarlet fever, which had been 28, 18, and 19 in the three preceding weeks, fell to 14 last week, and included 2 in London and 2 in Birmingham.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had increased from 2112 to 2570 in the four preceding weeks, had further risen to 2818 on Saturday last; 499 new cases were admitted during the week, against 346, 473, and 508 in the three preceding weeks. These hospitals also contained on Saturday last 977 cases of diphtheria, 194 of whooping-cough, 65 of measles, and 61 of enteric fever, but not one of small-pox. The 1092 deaths from all causes in London were 74 fewer than the number in the previous week, and corresponded to an annual death-rate of 12·6 per 1000. The deaths referred to diseases of the respiratory system, which had been 132, 125, and 134 in the three preceding weeks, declined to 124, and were 67 below the number recorded in the corresponding week of last year.

Of the 4651 deaths from all causes in the 96 towns, 176 resulted from various forms of violence and 346 were the subject of coroners' inquests. The causes of 35, or 0·8 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in 13 of its 14 suburban districts, in Manchester, Bristol, Bradford, Hull, Newcastle-on-Tyne, Nottingham, and in 55 other smaller towns. Of the 35 uncertified causes of death, 4 were registered in Birmingham, 4 in South Shields, 3 in Liverpool, 3 in Darlington, and 2 each in Stoke-on-Trent, West Bromwich, and Southport.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns, with an aggregate population estimated at 2,259,600 persons at the middle of this year, 1051 births and 627 deaths were registered during the week ended Saturday, Oct. 4th. The annual rate of mortality in these towns, which had been 16·4, 14·4, and 15·1 per 1000 in the three preceding weeks, fell to 14·5 per 1000 in the week under notice. During the thirteen weeks of the quarter just ended the mean annual death-rate in these towns averaged 14·3, against 12·7 per 1000 in the 96 large English towns. Among the several towns the death-rate last week ranged from 7·5 in Kilmarnock, 9·5 in Hamilton, and 10·2 in Falkirk, to 17·4 in Greenock, 17·9 in Dundee, and 20·8 in Leith.

The 627 deaths from all causes were 26 fewer than the number in the previous week, and included 81 which were referred to the principal epidemic diseases, against 94 and 90 in the two preceding weeks. Of these 81 deaths, 43 resulted from infantile diarrhœal diseases, 14 from diphtheria, 8 from measles, 7 from scarlet fever, 5 from whooping-cough, and 4 from enteric fever, but not one from small-pox. These 81 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·9, against 2·5 per 1000 in the 96 large English towns. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had been 96, 62, and 55 in the three preceding weeks, further declined to 43 last week, and included 18 in Glasgow, 9 in Dundee, 4 in Edinburgh, 4 in Aberdeen, and 3 in Leith. The deaths referred to diphtheria, which had steadily increased from 5 to 10 in the five preceding weeks, further rose to 14 last week; of this number 5 occurred in Aberdeen, 4 in Glasgow, and 2 in Edinburgh. The fatal cases of measles, which had been 12, 9, and 10 in the three preceding weeks, fell to 8 last week, and comprised 7 in Glasgow and 1 in Edinburgh. The deaths attributed to scarlet fever, which had been 4, 4, and 5 in the three preceding weeks, rose to 7 last week, of which 2 were registered in Aberdeen. The 5 deaths referred to whooping-cough, including 3 in Glasgow, were slightly below the average in recent weeks. Of the 4 fatal cases of enteric fever, 2 were recorded in Glasgow, 1 in Dundee, and 1 in Falkirk.

The deaths referred to diseases of the respiratory organs, which had been 65, 63, and 66 in the three preceding weeks, further rose to 69 last week; 27 deaths were attributed to different forms of violence, against 17 and 26 in the two previous weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,199,180 persons at the middle of this year, 696 births and 415 deaths were registered during the week ended Saturday, Oct. 4th. The annual rate of mortality in these towns, which had been 21·1, 19·8, and 21·0 per 1000 in the three preceding weeks, declined to 18·0 per 1000 in the week under notice. During the 13 weeks of the quarter just ended the mean annual death-rate in these Irish towns averaged 18·2 per 1000; in the 96 large English towns the corresponding rate did not exceed 12·7, while in the 16 Scotch towns it was equal to 14·3 per 1000. The annual death-rate last week was equal to 20·1 in Dublin (against 12·6 in London and 14·8 in Glasgow), 13·2 in Belfast, 21·8 in Cork, 21·6 in Londonderry, 23·0 in Limerick, and 38·0 in Waterford, while in the remaining 21 smaller towns the mean death-rate was equal to 17·9 per 1000.

The 415 deaths from all causes were 68 fewer than the number in the previous week, and included 94 which were referred to the principal epidemic diseases, against 120 and 103 in the two preceding weeks. Of these 94 deaths, 78 resulted from infantile diarrhœal diseases, 5 from scarlet fever, 4 from whooping-cough, 3 from enteric fever, and 3 from diphtheria, and 1 from measles, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 4·1 per 1000; in the 96 large English towns the corresponding rate was 2·5, while in the 16 Scotch towns it did not exceed 1·9 per 1000. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had been 111, 98, and 84 in the three preceding weeks, further declined to 78 last week, and included 26 in Dublin, 15 in Belfast, 8 in Londonderry, 6 in Portadown, 5 in Cork, 5 in Waterford, and 3 in Queenstown. The deaths referred to scarlet fever, which had been 4, 6, and 3 in the three preceding weeks, rose to 5 last week, and comprised 3 in Belfast and 2 in Dublin. Of the 4 fatal cases of whooping-cough, which were slightly below the average in recent weeks, 3 occurred in Galway and 1 in Dublin. The 3 deaths referred to diphtheria and 2 of the 3 deaths to enteric fever were recorded in Dublin. The fatal case of measles was registered in Newry.

The deaths referred to diseases of the respiratory system, which had been 41, 56, and 60 in the three preceding weeks, declined to 34 in the week under notice. Of the 415 deaths from all causes, 121, or 29 per cent., occurred in public institutions, and 7 resulted from various forms of violence. The causes of 16, or 3·9 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 96 large English towns the proportion of uncertified causes of death last week did not exceed 0·8 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Order in Council of April 1st, 1881, Deputy Surgeon-General Richard Aubrey Fitch has been placed on the Retired List (dated Sept. 27th, 1913).

The following appointments have been notified:—Fleet-Surgeons: J. E. Coad to the *Terrible* and for group of ships of Third Fleet; H. H. Pearse to the *Commonwealth*; F. J. Burns to the *Orion*; E. B. Townsend to the *Vernon*; J. C. Rowan to the *Audacious*, on commissioning, and as acting interpreter in German; and J. E. H. Phillips to the *Leander*, and for duty with torpedo boat destroyers. Staff-Surgeon: F. E. Anley to the *Weymouth*, on recommissioning; K. D. Bell to the *Victory*, additional, for disposal, and to the *Audacious*, on commissioning. Acting-Surgeon: P. B. Wallis to the *Victory*, additional, for Haslar Hospital, and for course of instruction at Naval Medical School, Greenwich College, and Royal Naval Hospital, Haslar.

ROYAL ARMY MEDICAL CORPS.

Royal Army Medical Corps Training Establishment: Lieutenant-Colonel Alexander A. Sutton, D.S.O., Royal Army Medical Corps, to be Commandant, vice Colonel George D. Hunter, D.S.O. (dated Sept. 20th, 1913).

Major Gerald S. Mansfield retires on retired pay (dated Oct. 4th, 1913).

Lieutenant-Colonel T. Du B. Whaite has been placed under orders to embark at Southampton for a tour of service with the Northern Army in India, and on arrival will be appointed for duty with the Third (Lahore) Division. Lieutenant-Colonel R. J. Geddes, D.S.O., late senior medical officer at Jubbulpore Cantonment, has been appointed an Honorary Associate to the Order of St. John of Jerusalem by His Majesty the King. Lieutenant-Colonel J. Fallon has been appointed to hold charge of the Military Hospital at Lahore on transfer from Dalhousie Cantonment.

Major H. B. G. Walton has been transferred from the Military Hospital at Bareilly Cantonment to Ranikhet. Major W. B. Winkfield has taken up duty at the Military Hospital, Maymyo, Upper Burma, on transfer from Meiktila Cantonment. Major G. Mansfield has been appointed to hold charge of the Military Hospital at St. Peter's Barracks, Jersey, in succession to Lieutenant-Colonel E. Davis, who has retired from the service. Major G. Baillie has been appointed to the Military Hospital at Colchester, on transfer from Yarmouth. Major A. A. Seeds has been transferred from the Military Hospital at Rawal Pindi Cantonment and appointed Senior Medical Officer at Kuldhana, Murree Hills District. Major P. H. Henderson has been appointed to the Military Hospital at Portsmouth, on termination of a tour of duty at the Royal Army Medical Corps Camp of Instruction at Tidworth Park, Salisbury Plain. Major S. M. Adye-Curran has arrived home on leave of absence from Sialkot Cantonment. Major S. H. Withers has taken up duty as Senior Medical Officer at Dagshai Cantonment, Simla Hills District. Major A. W. N. Bowen has been granted six and a half months' leave of absence home from India. Major J. Dorgan has embarked for a tour of service in South China. An exchange on the roster of service abroad has been approved by the Director-General between Major E. S. Clark, in charge of the Military Hospital at Holywood, and Major A. O. B. Wroughton, in charge of the Military Hospital at Maidstone. Major C. C. Cumming, specialist in bacteriology, has embarked for a tour of service at Malta. Major J. H. R. Winder has taken over medical charge of the Military Families Hospital, Wellington Lines, Aldershot. Major J. W. West has been appointed Specialist in Operative Surgery to the Second (Rawal Pindi) Division of the Northern Army in India. Major H. E. M Douglas, V.C., D.S.O., has been placed under orders to proceed to Egypt for a tour of service. Major G. St. C. Thom has taken up duty as Deputy Assistant Director of Medical Services (Mobilisation) to the Second (Rawal Pindi) Division of the Northern Army in India. Major T. J. Potter has been appointed Clinical Pathologist to the Military Hospital at Cairo. Major C. T. Samman has been appointed Specialist in Mental Science to the Fifth (Mhow) Division.

Captain J. E. Powell has been appointed to the Military Hospital at Hilsea. Captain G. H. Rees has been transferred from medical charge at Mosney Camp to the Military Hospital at Belfast. Captain M. Keane has been placed under orders to embark for a tour of service with the Ninth (Secunderabad) Division. Captain O. Ievers has been appointed to the Military Hospital at Chatham. Captain T. T. H. Robinson has been transferred from the Military Hospital at Lichfield to Strensall for a tour of duty. Captain G. A. Kempthorne has been transferred from the Royal Army Medical Corps Camp of Instruction at Tidworth Park, Salisbury Plain, to Tregantle Fort. Captain R. W. D. Leslie has been transferred from the Military Hospital at Gosport to Romsey. Captain M. C. Wetherell has been appointed to Kildare for duty at manœuvres. Captain L. Cotterill, instructor in musketry at the Royal Army Medical Corps Depôt, has been appointed to the First (Peshawar) Division of the Northern Army in India. Captain A. A. Meaden has been appointed to the Eastern Command for duty at the Military Hospital, Colchester. Captain W. H. Forsyth has been transferred from Tidworth Park, Salisbury Plain, to Netheravon for duty at the Cavalry School. Captain J. H. Campbell has been appointed to the Scottish Command for duty at the Military Hospital, Edinburgh. Captain H. C. Sidgwick has been appointed to the Royal Herbert Hospital at Woolwich. Captain J. McKenzie has been placed under orders for duty with the Eighth (Lucknow) Division of the Southern Army in India. Captain N. Low has been appointed to the Military Hospital

at Cosham. Captain G. G. Tabuteau has qualified at the Royal Army Medical College for appointment as Specialist in Operative Surgery. Captain R. H. L. Cordner has been appointed to the Aldershot Command. Captain H. J. Crossley has been placed under orders to embark at Southampton on Oct. 22nd for a tour of service in India and has been placed under orders for duty with the Seventh (Meerut) Division of the Northern Army in India. Captain R. G. Meredith has taken up duty in the London District. Captain F. E. Roberts has been appointed to the Military Hospital at Shorncliffe and has been selected for appointment as Specialist in State Medicine. Captain T. H. Gibbon has taken up duty at King George V. Military Hospital, Dublin. Captain F. C. Lambert has been placed under orders for duty with the Sixth (Poona) Division of the Southern Army in India. Captain J. E. Hoar has been appointed to the Military Hospital at Chatham. Captain A. H. Jacob has been transferred from the Military Hospital at Dublin to Wicklow and appointed to hold medical charge at the Murrough Camp. Captain C. W. O'Brien has taken up duty in the London District. Captain R. E. Humfrey has joined the Military Hospital at Cork for a tour of duty. Captain A. D. Fraser has been selected for appointment as Specialist in Bacteriology. Captain R H. MacNichol has been placed under orders to embark for a tour of duty in Malta.

Lieutenant B. H. H. Spence has been appointed to the Second (Rawal Pindi) Division. Lieutenant W. F. Christie has taken up duty in the Straits Settlements. Lieutenant S. P. Sykes has been placed under orders for a tour of service in India, and on arrival will be appointed to the Third (Lahore) Division of the Northern Army. Lieutenant C. C. Jones has taken up duty in the London District. Lieutenant C. J. H. Little has joined the Northern Command. Lieutenant W. Stewart has relinquished duty at the Military Hospital, Colchester, and embarked for service with the Seventh (Meerut) Division of the Northern Army in India.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel V. Drake-Brockman, Agency Surgeon at Meywar, has been placed under orders for transfer to Bhagelkhand.. Lieutenant-Colonel W. Ronaldson Clark has been appointed to hold civil medical charge at Jullundur. The services of Lieutenant-Colonel W. E. Jennings have been placed at the disposal of H.E. the Commander-in-Chief in India.

Major A. Murphy has arrived home on leave of absence from India. Major J. Watson has been selected for appointment as Agency Surgeon to the Eastern States of Rajputana by the Foreign Department of the Government of India. Major H. A. F. Knapton has been appointed to officiate as Sanitary Commissioner to the Government of Bombay Presidency. Major C. G. Webster, of the Madras Medical College, has been granted two years' combined leave of absence home from India. Major W. M. Anderson, second-class agency surgeon, has been appointed Residency Surgeon to the Gwalior State. Major A. G. Sargent has been appointed Superintendent of the Lunatic Asylum at Rangoon, in succession to Major W. H. Cox, D.S.O., granted leave of absence home from India. Major E. E. Waters has been appointed to officiate as Professor of Materia Medica at the Government Medical College, Calcutta, during the absence on sick leave of Major D. McCay.

Captain H. P. Cook has been appointed to the United Provinces of Agra and Oudh for employment in plague prevention duty. Captain J. V. Macdonald has been transferred from duty under the Home Department of the Government of India and reverted to military employment. Captain R. G. Croly has embarked at Bombay in medical charge of troops on board the s s. *Barjora* for service at Muscat. Captain H. N. H. Melhuish, plague medical officer at Rohtak, has been granted combined leave of absence home from India for six months. Captain N. S. Sodhi, plague medical officer at Gurgaon, has been transferred to the Ludhiana District. Captain H. C. Keates has been appointed to hold civil medical charge at Campbellpore on return to duty from leave of absence. Captain S. H. Lee-Abbott has been appointed Civil Surgeon at Ferozepore on termination of leave of absence. Captain E. T. Harris, civil surgeon at Toungoo, has been transferred to Bassein and appointed to hold civil medical charge in succession to Captain E. A. Walker. The services of Captain T. G. F. Patterson have been placed temporarily at the disposal of the Government of Bombay Presidency for civil medical employment. Captain J. M. A. Macmillan, civil surgeon at Hoshangabad, has been granted privilege leave of absence. Captain J. Cunningham has been placed on special duty under the Director-General I.M.S., at Barisal Jail, in connexion with the prevalence of dysentery in Eastern Bengal jails.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

The undermentioned Lieutenants to be Captains:—Charles M. Page (dated Sept. 14th, 1913). Edward T. Holland (dated Sept. 28th, 1913). William M. Biden (dated Sept. 30th, 1913).

TERRITORIAL FORCE.

Royal Army Medical Corps.

3rd Lowland Field Ambulance, Royal Army Medical Corps: Lieutenant James Young to be Captain (dated August 8th, 1913).

North Midland Mounted Brigade Field Ambulance, Royal Army Medical Corps: Lieutenant William M. Hewetson resigns his commission (dated Oct. 8th, 1913).

Welsh Border Mounted Brigade Field Ambulance, Royal Army Medical Corps: Major Alexander G. Hamilton to be Lieutenant-Colonel (dated July 18th, 1913).

3rd London General Hospital, Royal Army Medical Corps: Captain Frederick Richard Miller, from the 6th London Field Ambulance, Royal Army Medical Corps, to be Captain in the permanent *personnel* (dated Sept. 10th, 1913).

ROYAL NAVAL MEDICAL SERVICE: EXAMINATION FOR APPOINTMENTS AS ACTING SURGEONS.

At the examination for the Naval Medical Service held on Sept. 29th and Oct. 1st and 2nd, 13 candidates were successful and obtained the following marks:—

	Marks.
J. S. Elliot, M.B., Edinburgh University	1703
A. J. Tonkinson, M.B., London Hospital	1686
A. R Sharrod, M.B., London Hospital	1643
T. J. Kilbride, M.B., Cecilia-street Medical School, Dublin	1578
A. E. Panter, B.A., M.R.C.S. Eng., L R.C.P., Cambridge University and King's College Hospital, London	1515
G. S. Harvey, M.B., University College, Cork	1483
J. P. Blockley, M.B., Edinburgh University	1470
W. H. Murray, L.R.C.P. & S., University College, Cork	1456
J. R. Haldane, M.B., Glasgow University	1455
G. H. Hayes, M.B., University College, Cork	1435
W. S. Birch, M.R.C.S. Eng., L.R.C P., King's College Hospital	1418
H. C. A. T. Cannon, L.R.C.P. & S., Royal College of Surgeons, Ireland	1380
H. J. Hopps, M.B., Edinburgh University	1338

The maximum number of marks obtainable is 2400.

DEATHS IN THE SERVICES.

Deputy Surgeon-General Nathaniel Norris (late A.M S.), at his residence, Chester, in his eighty-third year. He entered the service in 1855, and served with the Jowaki expedition in 1877 (medal and clasp). He was in the Afghan war of 1878–80, and was medical inspector on the lines of communication in the Soudanese Nile expedition of 1884–85 (medal with clasp and bronze star).

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Opening of the Medical Session.

Professor A. E. Boycott gave an address on Oct. 1st in the Medical School to inaugurate the session. He chose for his subject "The Aim of Pathology." Professor W. Stirling, in opening the course of lectures on physiology, gave an address under the title "Can you Believe Your Eyes?" The address was illustrated by many lantern slides of geometrical and other optical illusions, as well as by optical illusions of varying characters projected on the screen. He said that the wise saying of Solomon, "Hardly do we discern the things that are on earth, and the things that are close at hand we find with labour," still holds true. Illusions make up a large part of our daily life, while the fusion and continuity of impressions which give rise to many optical illusions are represented by the action of the thaumotrope and its latest offspring, the cinematograph. The light of the body is the eye, yet the great majority of mankind either do not see the

fraction of what is displayed to their organs of vision or they fail to interpret correctly what is presented before them. Ruskin said that the degree of vision that dwells in a man is the correct measure of a man, and "to see clearly is poetry, prophecy, and religion all in one." The sense of sight is the one in which we believe most implicitly, and the one which gives us the largest store of information regarding the world in which we live. So confident are we that what we see must be true, that the expression "Seeing is believing" has passed into a proverb. The possible field of error is larger in the case of vision than in any other sense-organ. Many illusions have their roots in normal mental life. If on seeing an object we believe, and the belief is demonstrably wrong, there is an illusion. Pictorial art is largely based on illusions. In architecture the ancient Greeks corrected the unpleasant optical illusion which columns with perfectly straight edges suggest—namely, the appearance presented by the shaft of being narrower at the middle of the column. They therefore gave to the middle of the shaft an increased diameter—a process known by the name of entasis. The Greeks also applied the same correction to the apparently vertical sides of a tower. In the course of his address Professor Stirling showed experiments to illustrate the after-effects of scene movements, such as the effects produced by gazing for a short time at a waterfall and then turning our eyes to the contiguous rocks, when the rocks appear to move upwards with a velocity equal to that of the falling water. The production of coloured fringes from non-coloured objects was illustrated by Benham's spectrum-top. The subjects of irradiation, contrast, direction of lines, and objects seen under familiar conditions were presented and explained.

Professor Stirling in addition on Oct. 3rd gave a demonstration of new cinematograph films to students and medical men on "Some Applications of Cinematography in Physiology, and more especially in the Teaching of Physiology." Professing himself to be a convinced believer in the value of cinematography in the teaching of physiology, the lecturer presented first a series of films to illustrate the movements of microscopic animals by the method known as "dark-ground illumination"; then he showed the protoplasmic movements of amœba and of some animalcules which are propelled by means of ciliary motion. The same method was adopted to show the movements of the white cells of the blood of the carp, which have their nucleus at the hind end of the cell. The circulating movements of the protoplasmic granules and chlorophyll granules within certain water plants were projected on the screen. The actual growth of the protoplasm of slime-fungi at the circumference of the organism, as well as the remarkable reversible movements in the protoplasm itself, could be seen by the whole audience. The astonishing corkscrew-like movements of the organisms known as spirochætæ were next shown. The circulation of the blood in a small crustacean—an Isopod—was demonstrated. The latest advance in cinematography which is known as "ultra-cinematography" was also illustrated. In this method the successive phases of movement are "slowed down." Impressions of a movement, such as walking, running, or the flight of a bird, are taken at the rate of 180 images per second. These images were projected in the ordinary manner—i.e., 16 per second, so that the audience could analyse with perfect ease the successive movements of the human limbs in locomotion, as well as the graceful movements of a pigeon flying freely in the open air under perfectly normal conditions. The beating of the heart in the open chest, when normal and during asphyxia, was projected, the movements being slowed from 10 to 20 times their normal speed, so that the successive stages of these movements could be analysed by the unaided eye. It is now well known that living embryonic tissues can be cut from the living body and can be cultivated in appropriate aseptic media for many days after removal from the body. The study of surviving excised tissues *in vitro* has been specially prosecuted in America by Harrison, Burrows, Carrel, Lambert, and others, and in France more especially by Levaditi and Comandon. Professor Stirling showed a small fragment of a spleen removed from a developing chick which was placed in a sterilised culture medium and kept at 37° C. The tissue lives for many days, and the audience could see the growth of the tissue itself, as well as the leucocytes emigrating from the piece of spleen and moving freely in the surrounding medium. A fragment of the embryonic heart of a chick showed the actual outgrowth in a radiate manner of elongated protoplasmic cells into the surrounding medium. More than this, some of the cells ceased to elongate, retract, become globular, and before the eyes of the audience were seen to divide into two new independent cells. The growth of cells from such a minute fragment of the heart fills the field of the microscope with fusiform cells in about eight hours.

Recommendations for Ambulance Provision.

In order to extend the ambulance service amongst the poorer classes the chief constable recommends that on the production of a medical certificate the free use of an ambulance be allowed to all householders who have, from all sources, an income of less than 35*s.* a week coming into the house. To secure the coöperation of medical men, and to prevent abuse as far as possible, practitioners should be supplied with a book of printed certificates, so that when called to a case requiring an ambulance they could fill in the certificate, giving the patient's full name and address, nature of disease, hospital to be conveyed to, and stating that in his opinion it was a case for free removal, and was non-infectious.

Mr. J. Carter Bell's Bequests.

Mr. Joseph Carter Bell, of Higher Broughton, public analyst for the county of Chester and for the county borough of Salford, after certain preliminary bequests, has divided the residue of his estate, approximately £30,000, into sixtieths, leaving three-sixtieths each to the Manchester Royal Infirmary, the Salford Royal Hospital, and the London Orphan Asylum at Watford. The remainder he bequeathed to relatives.

Oct. 6th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Treatment of Tuberculosis in Edinburgh.

To meet the increased demand for accommodation for phthisis patients at the city hospital for infectious disease the public health committee recently decided to erect two large open-air shelters there, each to accommodate 60 patients. Each is in the form of an elongated shed with an entirely open front, which can be easily partially enclosed by means of screens. The administration accommodation is very complete, comprehending excellent kitchen and bathrooms, and there is a large dining hall and also recreation room attached to each shelter. There is now accommodation at the city hospital for 180 cases, and with these new quarters it will be possible to have the early cases—for whom treatment must now be provided under the National Insurance Act—living under a different roof from the more advanced cases, for whom alone up to the present provision has been made at the hospital. There are at present, therefore, 92 vacant beds.

The Declining Birth-rate in Edinburgh.

An interesting return in this connexion is that made by the Edinburgh school board regarding enrolments in the day schools, which show a decrease of 748 as compared with September of last year. This fall off in numbers has taken place in the elementary schools alone, the returns for the higher grade showing a slight increase. One notes that out of 57,170 houses in Edinburgh with a rental of £30 or under, no less than 32,377 had no children of school age, which is an increase of 1798 houses in this category as compared to this state of affairs last year. The special schools showed an increase in enrolments of 12, the total being 496.

Sanatorium Benefits in Midlothian.

A statement issued by the Insurance Committee for the county remarks upon the small demand for treatment in the sanatorium. During the year there were only 32 applications, and as five were refused as being unsuitable for domiciliary or sanatorium treatment, but 27 patients were taken charge of. As the committee is allowed 9*d.* per head over the number of insured persons, which was taken as 35,000, a considerable surplus is carried over, the expenses to the committee for cases treated being only £469 as regards sanatorium benefit.

Royal (Dick) Veterinary College, Edinburgh.

At the opening of the new session of the Royal (Dick)

Veterinary College, it was announced that operations for the erection of the new college buildings were progressing rapidly, and would be pushed on with all speed in order that the classes might be transferred from the old buildings at an early date. The cost of the new buildings is estimated at £65,000.

Memorial to a Tiree Medical Man.

An interesting ceremony took place at Baugh, Island of Tiree, on Sept. 29th, the occasion being the formal inauguration of the memorial recently erected to the late Dr. Alexander Buchanan, of Tiree. The monument is composed of a shaft of Aberdeen red granite, 10 feet high, resting on a solid granite pediment, encircled in a rough cairn of sea-worn boulders, the whole erection rising to a height of 17 feet from the ground. The eastern face of the pediment bears the following inscription:—"In loving memory of Dr. Alexander Buchanan, born at Callander 4th October, 1835, died at Tiree 29th April, 1911, for 51 years the medical officer and loved and valued friend of the islanders." At the unveiling ceremony reference was made by various speakers to the love and respect in which Dr. Buchanan had been held throughout the island.

The Tuberculosis Order in Glasgow.

The executive committee formed by the corporation of Glasgow under the Diseases of Animals Acts have brought forward a proposition that certain work should be transferred from the health department to their department with a view to assisting the veterinary inspector in carrying out the Tuberculosis Order, 1913. The Order from the Board of Agriculture and Fisheries aims at the destruction of bovine animals suffering from tuberculosis. If it is to be effectively carried out there should be a regular inspection of the dairies and byres within the city. The work of inspection, it is suggested, will be similar to what is being done at present, but in addition to that work arrangements will have to be made for the valuation, slaughter, post-mortem examination, and testing with tuberculin of all bovine animals (not cows alone), and the sale of the carcasses. The veterinary inspector is to be authorised to deal with these matters, but where the owner does not consent to the slaughter of a tuberculous animal or its value exceeds £30 the inspector is to advise the town clerk, who shall communicate with the Board of Agriculture and Fisheries.

Special Reservists and Measles: the Outbreak in the Outer Islands.

At a meeting of the public health committee of Inverness-shire held on Sept. 30th, a letter was read from the headquarters, Scottish Command, in reference to the introduction of measles to the outer islands by special reservists. A resolution anent the matter passed at the last meeting of the county council had been forwarded to the chief medical officer of health, headquarters, Scottish Command. The following points were noted in the communication: 1. As the maintenance of the health of the troops is of very great importance, these soldiers are under constant and close medical supervision while in camp. The outbreak of infectious disease is thus discovered as soon as possible after the appearance of initial symptoms, and contacts are speedily isolated. 2. Every endeavour is made to ensure that soldiers in an infectious condition are not allowed to mix with the civil population, and special steps are invariably taken for the medical inspection of the men of the Special Reserve just before disbanding. 3. No complaints of the spread of infection from this source have been received from other parts of Scotland. 4. Though men actually sick can be detained, it is not in the power of the military authorities to detain healthy men or contacts beyond their training period. To do so would require a special Act of Parliament. I may mention also that the financial aspect of this part of the question presents insuperable difficulty. The letter goes on to regret the occurrence of the epidemic referred to by Dr. Murdo T. Mackenzie, and to give assurance that every effort will be made in the fnture by the military medical authorities, as far as lies in their power, to prevent the repetition of such an unfortunate incident.

Diphtheria Epidemic in Aberdeen.

A severe epidemic of diphtheria is at present raging in Aberdeen. Fortunately the majority of the cases have not been of a severe type. On the advice of the medical officer of health the water-supply at the various schools in the city was turned off on the 26th of last month. At a meeting of the Aberdeen school board held on Sept. 26th the chairman, in answer to a question, said that he thought it was rather the use of the drinking mugs at the schools that was objected to than to the use of the water itself.

The late Dr. Gavin Tennent.

Dr. Gavin Paterson Tennent, whose death was recorded in these columns on Sept. 27th, bequeathed £25,000 to the University of Glasgow. A point in his life also, I think, deserves further mention. In his younger days he had a large experience of relapsing fever, a disease known only by name to the majority of the profession at the present day. In 1867, the year in which he graduated, there were many Glasgow practitioners who remembered the epidemic of relapsing fever in the year 1843, when there were 32,000 cases in eight months. In March, 1870, the disease reappeared in the city, Dr. Tennent being resident physician in the fever hospital then in Kennedy-street. At the end of October of that year the routine work of the wards became so heavy that elaborate clinical records could no longer be compiled, but Dr. Tennent had already collected copious data relative to 352 successive cases, and published an analysis of them in the *Glasgow Medical Journal* for May, 1871.

Oct. 7th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Irish Medical Committee.

THE new Irish Medical Committee has issued a circular, copies of which are to be sent to the members of the profession by the secretaries of the various Local Medical Committees. An account of the formation of the Irish Medical Committee is given, and attention is drawn to the critical position in which Irish doctors have been placed by the statement made by Mr. Lloyd George in the House of Commons on August 14th, to the effect that, if a scheme could be devised for certification which was satisfactory to the medical profession and the Approved Societies, he would be prepared to ask Parliament to increase the grant by such amount as may be necessary, subject to the limit of 2*s.* 6*d.* per insured person which has been imposed. Further, it is pointed out that in the struggle which is likely to take place in Ireland over the extension of medical benefits—based on the recommendations of the Majority Report of the Treasury Interdepartmental Committee—the medical profession will have no security, except in its own united action, against the gravest injury to its status, its interests, and the efficiency of its work. An appeal is therefore made for financial support for the expenses of this struggle, and it is expected that members of the medical profession will forward not less than £1 as their present subscription. The difficulty is that the expenses of the Local Medical Committees—which are not small—must be met in the first instance.

Infantile Mortality in Dublin.

The high rate of infantile mortality in Dublin during the past few weeks gives cause for anxiety. In particular, the prevalence of diarrhœa and enteritis is alarming. To some extent the unusually dry season is responsible, but it cannot be doubted that the distress consequent on the industrial dispute has made matters much worse. In the four weeks ending Sept. 27th there were 107 deaths of children under 2 years of age from diarrhœal diseases. It is noticed by residents in Dublin that the number of flies has been abnormally great this autumn, and there is little doubt that this has been a factor in the spread of disease. With a view to diminishing the propagation of flies, the public health committee advises the cleansing of lanes and courts not in charge of the corporation. The streets and lanes in charge of the corporation are, however, far from clean, and no attempt is made to enforce the law against private owners. An instructive correspondence has passed between the public health committee and another committee of the corporation, the cleansing committee. The former requested the latter to water the streets before sweeping, in order to keep down the dust. The cleansing committee replied that the water in the city reservoir was low, and economy was required. In response the public health committee pointed out that water could readily be obtained from the canals for watering the streets. Of this suggestion no notice was taken, and on the

rare occasions when the streets are swept the dust is raised in clouds to the tops of the houses.

Treatment of Tuberculosis in Belfast.

The scheme for the treatment of tuberculosis devised by the corporation of the county borough of Belfast having now been approved of by the Local Government Board for Ireland, and the Treasury having now written to guarantee the share to be borne by them, which will amount to £16,745 13*s.* 4*d.*, according to the estimate, the arrangement will shortly come into being. The White Abbey Sanatorium, built and at present run by the Belfast board of guardians, is to be taken over by the city corporation. In the meantime, a very keen canvass is going on for the post of chief tuberculosis officer, who is to have a salary of £600 a year.

Oct. 7th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Académie de Médecine.

THE permanent secretary of the Académie de Médecine has been authorised to accept in its name the legacy of M. Pannetier, made in his will dated Dec. 10th, 1908. This legacy consists of 100,000 francs, the proceeds to be devoted to the establishment of an annual prize for the author of some discovery in medicine or surgery, or to any person who shall be distinguished for the application of recent discoveries. If during one or more years the prize cannot be awarded, the interest is to be added to the capital, to augment the proceeds in the ensuing years. The sum bequeathed is to be invested in French three-per-cents. in the name of the Académie de Médecine, the destination of the proceeds being duly recorded.

The Sale of Poisonous Substances.

Oct. 7th has been set aside for discussion at the Académie de Médecine of a proposition advanced by many of the members for a Bill to modify the ordinance governing the sale of poisonous substances. At present no one who does not hold a pharmacist's diploma or is not authorised by the laws in force to dispense medicines under exceptional conditions to his patients may supply for use in human or veterinary medicine the poisonous substances contained in Table A, which may be dispensed only on the prescription of a medical man, of a veterinary, or of persons authorised especially to prescribe them. The author of the prescription must sign and date the prescription and give his name and address and the doses of the said poisons, and must indicate their mode of administration. Ergot and corrosive sublimate may be supplied on the prescription of a midwife. In default of any contrary indication by the author, every prescription containing poisonous substances in Table A may be repeated by pharmacists, but prescriptions containing aconitine or its salts, hydrocyanic acid, potassium cyanide, digitaline, hashish and its preparations, strophanthine, veratrine or its salts, may not be repeated either by the pharmacist who first dispensed the prescription or by any other. The same prohibition extends to prescriptions ordering the alkaloids of opium or cocaine, as well as their salts or derivatives, but only when these products are prescribed by themselves or in the form of solutions for injection. It applies also to powders with a cocaine base or one of salts containing these substances in a proportion of or above 1 per cent. Pharmacists must enter their prescriptions on a register and enter also renewals thereof. When they retain the prescription they must return to the patient a signed and dated copy. These articles of the law leave many loopholes. It appears insufficient to authenticate prescriptions by signing and dating them and legibly appending the name and address. It would be a good plan to enjoin the use of a stamp or an adhesive wafer bearing the name and address of the medical man, together with his number on the official register. It is also very dangerous for the medical man as well as for the pharmacist, and opposed to the interests of the public health, to permit the repetition of any prescription containing poisonous subjects without renewal by its author; first, because the prescription was written to apply only to a determined condition, and the medical man alone can determine other cases in which the prescribed medicaments are suitable; next, because, since it is forbidden to supply the drugs without a prescription from a medical man, it may be equally or even more dangerous to repeat them without the advice of him who is the sole judge of the fitness of repeating them. Dr. Desesquelles therefore proposes to replace this entire article of the law by the following: In the absence of any contrary indication by the author of the prescription, no prescription containing any of the poisonous ingredients in Table A may be repeated by pharmacists. The supplying of aconitine or its salts, of hydrocyanic acid, of potassium cyanide, digitaline, hashish or its preparations, must not be repeated without a fresh prescription from a medical man, the prescription being dated and legibly signed and bearing the medical man's name and address.

The Collège de France.

The Minister of Public Instruction has signed the decrees whereby the number of chairs in the Collège de France is reduced from 43 to 40, the suppression to take place as the chairs fall vacant. The annual salaries of the 40 professors of the college are fixed at 12,000 francs.

Conferences on Electricity, X Ray, and Radium.

The Société des Médecins Chefs des Laboratoires de Radiologie et d'Electro-radiothérapie des Hôpitaux de Paris organises twice yearly, in November and May, a series of theoretical and practical conferences on electricity, X ray, and radium, lasting for one month. The first series will take place from Nov. 3rd to Dec. 2nd of this year in the amphitheatre of the Hôpital de la Pitié, 83, Boulevard de l'Hôpital, for the theoretical part. The practical part—that is to say, practical demonstrations in electrology, X ray work, and radium work—will be held in the mornings in the laboratories of radiology and of electro-radiotherapy of the Paris hospitals. Those attending will be divided among the various hospitals in parties of ten at most. The parties will be formed at the close of the conference on Monday, Nov. 3rd. There is no subscription. Intending entrants must register with Dr. Delherm, Hôpital de la Pitié, or with Dr. Aubourg, Hôpital Boucicaut.

Attempted Murder of a Medical Man by a Madman.

Dr. Philippe, who is at present doing duty for a *confrère* at Saint Mandé, was called to see a man aged 25. Shortly before midday the medical man, on presenting himself at the address given, was received by the patient, who took him into the dining-room and offered him a paper to read. The paper contained an inconsequent jumble of words. Unsuspectingly the doctor examined the patient, auscultated him, and put a few questions. Suddenly the patient seized a couple of knives and threw himself on the doctor. The latter seized his aggressor by the wrists and with a violent effort forced him into a corner, then hurriedly escaped, not, however, before he had been wounded, though only slightly, on the hand, the left eyebrow, and the upper lip.

Burglars at the Hôpital de la Charité.

An attempt has been made to rob the strong room of the Charité, but the thieves succeeded only in carrying off some 20 francs that they found in an office drawer. An unsuccessful attempt was made to open the strong room with a false key. It has been clearly shown that the thieves could not have broken in at night, but must have been in the building, and are probably there now. Both honest men and rogues are taken care of at the hospital. Pay-day for the *personnel* is on the 29th of each month. On the 28th the cash—some 50,000 francs—is brought from the bank and placed for the night in the safe. The thieves were certainly acquainted with this detail, since they attempted their *coup* on that day. But the 28th being a Sunday the money had not been brought, and the strong room contained only the remainder from the last pay-day.

Oct. 6th.

GUILD OF ST. LUKE.—At the annual service of the guild, which will be held in St. Paul's Cathedral on Tuesday, Oct. 21st, at 7.30 P.M., the sermon will be preached by the Rev. Canon Arnott, F.R.C.S., rector of Beckenham. Admission will be by ticket, to be obtained from the Provost, Mr. George Cowell, F.R.C.S., 24, Harrington-gardens, London, S.W. A stamped addressed envelope should be enclosed with the application.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Statistics of Cancer.

ACCORDING to Professor Behla, one of the medical members of the Prussian Statistical Office, the number of deaths from cancer has again increased in 1912 as compared with the preceding year, 30,045 deaths from cancer having been reported in 1912 against 29,473 in 1911. The increase in cancer mortality has been continuous during recent years, whilst the death-rate from tuberculosis is constantly decreasing. New methods of treatment have thus failed to produce a decrease in the mortality, and it will be of interest to see from future statistics whether this will continue to be the case after the introduction of modern radiotherapy. Professor Behla draws attention to the remarkable fact that the cancer mortality of the year is always greatest in the autumn.

A Municipal Subvention to the Berlin Medical Society.

The Berlin Medical Society has hitherto not been in possession of premises of its own, the Langenbeck House, where the meetings take place and where also the offices and library are accommodated, being the property of the German Surgical Association, and only rented from them. The Langenbeck House has long since proved much too small for the increasing number of members of the Medical Society, and the society has therefore decided to build a new house of its own, to be called the "Virchow House." The purchase of a site in the medical quarter of Berlin, however, has exhausted the funds at the disposition of the society, so that but little money is left for the cost of building. The committee of the society some time ago petitioned the municipal authorities of Berlin to grant to the society a subvention on account of the valuable work done by the society for public health. The town council has, indeed, after a thorough discussion, decided to grant the request and to give to the society an annual sum of £500 for five years, beginning with Oct. 1st, 1914, and further, to lend the sum of £50,000 on mortgage on the premises. In this way the Medical Society is at once relieved from its financial difficulties and will be able to begin building the new premises. This generous decision of the Berlin municipal authorities is highly appreciated in medical quarters. The plan of co-operating with the German Surgical Association in constructing a large house to be used in common has been abandoned, the negotiations for that purpose not having led to any practical result, although the Langenbeck House also is much too small for the Surgical Association, so that their last two meetings had to be held outside the Langenbeck House in a large concert hall.

The Noise in Modern Hotels.

Professor Oppenheim, the well-known specialist for nervous diseases, has been drawing public attention to certain drawbacks connected with modern hotels, notwithstanding the great progress made in their construction and management. He refers to the noise produced by lifts and by the hot-water arrangements for a great number of bathrooms and lavatories. Matters are made worse by the thinness of the partitions between the hotel rooms, which allow every noise in the neighbouring rooms to be heard, notwithstanding double-doors and double-windows. The situation of the leading hotels in busy thoroughfares does not favour quietness, and in the back rooms the noise is sometimes as annoying as it is in front. But the greatest nuisance of all is the excessive supply of music. Formerly musical performances took place only in the evening and in certain hotels; nowadays every hotel, from the fashionable ones in the great cities to the more unpretending inns in remote mountain places, has its house band, which performs at least twice a day. Music, as Professor Oppenheim says, is truly a great delight, but only under certain conditions, and the individual hotel resident should have the choice whether he wishes to hear music or not, whilst under present conditions he has no means of escaping it, even should he prefer to seek quietude in a retired corner. The hotel managers, Professor Oppenheim suggests, should discuss the question at their forthcoming congress; he is certain that it would be a great comfort to many of the guests, especially to those in a nervous condition, if they would alter the present noisy state of things.

Oct. 6th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

An International Congress against Alcohol at Milan.

THIS is a season of congresses, of which perhaps the most important has been the International Congress against Alcohol, inaugurated at Milan on the 22nd of last month. The Onorevole Falcioni, Under Secretary of State, represented the Government and welcomed the delegates, who included representatives of 28 different countries. The committee had kept in view the most important point of the alcohol question as it affects this country, and instead of inviting the Congress to philosophise over the vice of inebriety and enthuse over the virtues of abstinence they had placed before it the economic problem, vital to Italy, of the utilisation of the fruit of the vine apart from the production of alcohol. It appears that the work of Italians has gone far towards the solution of this problem in the preparation of a grape juice concentrated by a cold process. This gives an economical, pleasant, and nutritious drink containing phosphorus in combination as lecithin and nuclein in proportions much higher than in wine. Experiments have shown the ease with which it is assimilated and proved its nutritive value for children and delicate subjects.

The Congress of Sciences at Siena.

Another interesting congress has been that of the sciences held at Siena last week. Medical sciences were well represented. Professor Sclavo's address on the Rights of Hygiene was an outspoken criticism on the state of affairs obtaining here. He told an amusing story of a doctor who, having obtained funds for the acquisition of a site for a home for children with a tendency to tuberculosis in a fine position overlooking the sea, received a summons to the prefect, who advised him to drop the project as he would never allow him to open an establishment of such a kind, so full of danger to the fish in the sea below! Professor Sclavo found both medical men and engineers deficient in education in matters of public health, and deplored the great waste of public money which this ignorance has caused. Professor Centanni reported some original observations on the behaviour and development of tissues in artificial conditions. Making use of a modification of Carrel's technique, he had studied the means to stimulate the growth of tissues and to produce pathological formations. He expressed the conviction that this line of research promised important practical results. For the entertainment of the congress the municipal authorities arranged a third performance of the "Palio," the mediæval horse races, of which the usual two performances take place in July and August in the Piazza del Campo.

Oct. 4th.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Canadian Public Health Association.

AT the third annual congress of the Canadian Public Health Association, held in Regina, Saskatchewan, on Sept. 18th, 19th, and 20th, under the presidency of Dr. John W. S. McCullough, chief health officer of Ontario, a resolution was adopted affirming that advanced cases of tuberculosis could be treated in general hospitals without the danger of infection to other patients, providing proper arrangements were made, and copies were ordered to be sent to the Provincial Governments, asking that provision be made in all hospitals receiving Government aid. A resolution was adopted also asking the Dominion Government to take into consideration the danger to the public health through the yearly increasing number of immigrants from European countries into Canada. The following officers were elected for 1914: President, Dr. M. M. Seymour, Regina. Vice-presidents, Dr. J. D. Page, Quebec; Dr. T. Aird Murray, Toronto; and Dr. Duncan Anderson, Toronto. General secretary, Dr. Lorne Drum, Ottawa. Treasurer, Dr. G. D. Porter, Toronto. Fort William and Port Arthur will be the place of meeting in 1914.

Sanitary Services Convention, Quebec.

The fifth annual conference of the Sanitary Services of the Province of Quebec was held in Montreal during the week

ending Sept. 20th, and presided over in the absence of the chairman of the Quebec Board of Health, Dr. E. P. Lachapelle, by its secretary, Dr. E. Pelletier. Dr. J. E. Laberge, of Montreal, insisted that instruction in hygiene should be made compulsory in all the schools of the province. He outlined 12 lessons, which could be subdivided into four parts, so that ample time could be devoted to all phases of the subject. At an evening session, Dr. T. A. Starkey, Professor of Hygiene in McGill University, gave a public lecture on the Responsibility of Municipalities in carrying out Sanitary Measures, which was followed by another lecture by Dr. C. N. Valin, Professor of Hygiene in Laval University, on the Advantages of Public Hygiene. Dr. A. Simard, of Quebec City, dealing with infant mortality, said that at least 2000 babes could be saved from death in that province with better care, proper sanitation, and hygiene. The conference also advocated the proper medical inspection and supervision of school children in all the elementary schools of the province.

Public Health Legislation in the Province of Quebec.

The Provincial Board of Health of the Province of Quebec was first organised in 1887, Dr. Lachapelle, of Montreal, being appointed president, and Dr. Pelletier, of Quebec City, secretary. After 26 years these two officers still continue in control of health matters in that province and to them is due the credit of the excellent Public Health Acts now in force. The board consists of nine members, four of whom must be physicians. In 1910 it was decided to divide the province into ten health districts, and six of these districts have since been organised with medical men in charge located in each district. All medical inspectors are required to hold a diploma of public health and to pass an examination prescribed by the Board of Health. Special attention is given to small-pox—always a menace throughout that province—and the Vaccination Act provides for vaccination in the first year after birth, and revaccination both in the eleventh and twenty-first years. During the present year in Montreal there have been 222 cases of small-pox—March heading the list with 51—and 1204 cases of tuberculosis—967 pulmonary and 237 of other forms.

Insanity in Quebec and Ontario.

In the Province of Quebec the care of the insane is under somewhat peculiar conditions, being entrusted to corporate bodies, religious or otherwise, by the Government, which makes a per capita grant for the public patients, who are allotted to the different institutions as follows: St. Jean de Dieu, 2000; Quebec Hospital for the Insane, 1257; Verdun Protestant Hospital, 515; St. Ferdinand Hospital, 145; St. Anne Hospital, 123—a total of 4040 public patients. Only Verdun makes returns of its private patients, and these number practically the same as the public patients. If the ratio in others is the same the officially insane in that province would approximate 8000. The amount paid by the Government for the public patients is $460,738.36. For the Roman Catholic institutions this is $112 per capita, while for the Verdun patients it is $142. Quebec has a total population of 2,000,000.

In Ontario for the last official year the total number of insane in the provincial institutions was 5726, 2769 being males and the rest females, a net increase of 86 for the year. The admissions for the year totalled 1247, an increase of 103; the deaths, 460, an increase of 45; and the discharges, 570, an increase of 28. The number of deportations was 258, an increase of 32, 66 being insane, 49 criminal, and 48 likely to become a charge upon the province. Manual and health work has been found most beneficial in lessening mental degeneracy, and a high standard of efficiency has been reached in the various institutions. The growth of insanity in the province is seen in the following statistics: 1882 to 1886, total 2775; in 1891, 3201; 1895, 3865; 1901, 4604; 1906, 4933; 1912, 5517. Of the 1247 admitted in the past year 890 inherited a predisposition. Of the admissions of the year 653 were men and 594 women, of whom 543 were single, 587 married, 116 widowed, and 1 divorced.

Dominion Medical Council Matters.

At the first examinations of the Dominion Medical Council held in Montreal on Sept. 7th some 66 candidates presented themselves. At the recent annual meeting the Ontario Medical Council instructed its registrar to accept Dominion registration as full qualification for licence in Ontario, subject only to the production of the necessary credentials and payment of the usual fee. Four provinces have now established reciprocity with Great Britain—namely, Quebec, Prince Edward Island, Nova Scotia, and New Brunswick. Only one province, British Columbia, has failed to comply with all the requirements of the Dominion Act. It retains the right to examine candidates for subsequent licence in that province in the final branches.

Sept. 23rd.

NOTES FROM SOUTH AFRICA.

(FROM OUR OWN CORRESPONDENT.)

Immigration Regulations.

A SERIES of regulations has recently been promulgated under the Union Immigration Act passed last session. Under these regulations the port health officer or other duly appointed medical practitioner is to be present at the examination of passengers by the immigration officer and to indicate any passenger whom he deems it necessary to examine medically before he is passed as an immigrant. Leprosy, trachoma, favus, frambœsia, syphilis, and scabies are declared loathsome diseases, bringing those suffering therefrom under the category of prohibited immigrants. The regulations provide that persons suffering from tuberculosis may be allowed to land under a permit from the immigration officer, but these permits are only to be issued at the ports of Cape Town and Durban, and on the following conditions. The place of residence and the mode of transport thereto to be subject to the approval of the immigration officer, the immigrant to report himself to the local health authority at his place of residence, and to present himself for examination by the district surgeon or other approved medical practitioner whenever required; sleeping accommodation never to be shared with any other person, and regulations by the local health authority for preventing infection to others to be observed. It is clearly the policy of the Government to discourage the entry into the Union of tuberculous persons, although very little is being done to prevent the spread of the disease in the subcontinent itself. But with no properly organised health department the regulations are likely to be applied improperly or to become a dead letter.

Reorganisation of Hospital Work in the Cape Peninsula.

The Cape Hospital Board has appointed a committee of inquiry to advise as to the requirements of the Cape Peninsula and the reorganisation of work under the new *régime*. The committee having sought the advice of the Cape of Good Hope (Western) Branch of the British Medical Association, the Association approved the formation of a clinical medical school, but as that would require some years of preparation it recommended that the board keep steadily in view the provision of a large hospital for the university medical faculty. It recommended the early establishment of a pathological department under the control of a university medical faculty, and considered it desirable that the New Somerset Hospital should be entirely reserved for free patients with a view to its development into a teaching hospital, though the site of that hospital is hardly ideal, not being in the neighbourhood of the medical school. It recommended that the honorary staff should be specialised and the principle gradually introduced of requiring the staff to restrict themselves in private practice to their specialty. Also that, when a complete medical course was established, beds should be reserved for the university professors, and that in the meantime all holders of appointments as honorary visiting medical officers be selected by a mixed committee representing the lay board, the honorary staff, and the outside profession. It further recommended that free out-patients be treated at both the New Somerset Hospital and the Free Dispensary by an honorary out-patient staff appointed for the purpose; that the four suburban hospitals should, as at present, be conducted on the lines of cottage hospitals; that maternity blocks should be attached to the teaching hospital; and that an entirely new hospital on the small ward system should be built in as central a position as possible for contributing patients. Finally, it stated emphatically

the opinion that it was unnecessary for the board to make provision for fully paying patients.

South African District Surgeons' Association.

At a meeting of the district surgeons representing all provinces of the Union recently held at East London, on the suggestion of the Transvaal District Surgeons' Association it was unanimously agreed to form a South African District Surgeons' Association, with a local committee in each province. The following provisional committee was appointed: Dr. Grinsell (Stutterheim) and Dr. E. G. Dru Drury (Grahamstown), representing the Cape Province; Dr. D. Campbell Watt (Pietermaritzburg) and Dr. J. Dodd (Ixopo), representing Natal; Dr. Moorhead (Rustenburg) and Dr. Nixon (Heidelberg), representing the Transvaal; and Dr. D. M. Tomory (Bloemfontein) and Dr. P. D. Strachan (Philippolis), representing the Orange Free State. Dr. Campbell Watt was unanimously elected the first president and Dr. Moorhead vice-president, and Mr. W. A. J. Cameron, of Johannesburg, a temporary secretary. The rectification of the grievances of district surgeons under the existing regulations, and the contemplated promulgating of new regulations curtailing many of the existing fees, were the determining causes of the new association.

Railway Sick Fund Regulations.

The long awaited new regulations for the administration of the Railway Sick Fund under Union are at last gazetted. The control of the fund is to be in the hands of a central board of 16 members, half to be nominated by the administration and half elected by contributors. No provision is made for medical representation, although it is possible that the administration may intend to nominate one or two medical men as their representatives. Subordinate to the board are to be four district boards with offices respectively at Cape Town, Bloemfontein, Johannesburg, and Durban. On these also there is no specific provision for medical representation. The objections to the regulations are very numerous. The new regulations are understood to have been compiled without reference to contributors to the fund, to the medical men concerned, or to the medical profession. It is of the utmost importance to the railway employees that their medical service should be an efficient one. The medical officer has hard work to do his duty both to the railway administration and to the patient. It is utterly impracticable for laymen unassisted by professional advice to draw up satisfactory regulations; yet this is what the railway administration has endeavoured to do. The new regulations are perhaps objected to more strongly in Natal than elsewhere. At a meeting of the Durban branch of the British Medical Association recently convened to consider the terms offered by Government for medical officers to the new Railway Sick Fund, Dr. R. K. Howden stated that he had been offered the appointment as railway medical officer to the Greyville district. There were 2380 (estimated) railway workers in this district, including wives and children of the actual employees. He was offered £500 per annum. A few extras were allowed, the chief being £2 2*s.* for midwifery cases and £1 1*s.* for anæsthetics and for consultations; also a travelling allowance of 8d. per hour when absent from headquarters on duty. He had worked out the remuneration offered, and it came to slightly less than 4*s.* 2*d.* per head per annum. With women and children included a fair estimate of the incidence of sickness would be 3 per cent., giving about 60 attendances per diem. This was more than one man could manage, and if an assistant and two motor-cars were kept it would all have to come out of the £500 per annum. Dr. Howden further pointed out that the majority of these people had previously been private patients, so that practices would be broken up and for ridiculously low rates of payment. He might well also have added that in addition there would be interminable correspondence connected with such a post. From the general discussion it was evidently the consensus of opinion that the terms were totally inadequate and should be strenuously resisted. Eventually resolutions were agreed to calling for conference with other branches as to their attitude, standing by the 12*s.* minimum rate for adult workers and adopting the principle of free choice of doctor, and informing the Central Board that members of the branch would not be allowed to negotiate individually for the posts of railway medical officer until terms were accepted by the branch and inviting a conference between the board and the branch. Dr. Howden, Mr. S. Copley, Mr. B. A. Nicol, Dr. A. McKenzie, and Dr. Duncan McKenzie were appointed a committee to deal with the matter and, if necessary, to meet a delegation from the sick fund and to report to the branch. The firm stand taken up by the Durban practitioners is very satisfactory.

Sept. 5th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Medical Research in India.

THE first number of the new Indian *Journal of Medical Research*, edited by the Director-General of the Indian Medical Service and the Sanitary Commissioner with the Government of India, is now under issue as a quarterly. It is published for the Indian Research Fund Association and takes the place of the Scientific Memoirs. Sir Harcourt Butler in a foreword says: "The time has come for the fund to have its own official organ, and the *Journal* should be a worthy record of what is being done in India for the advance of sanitary science in the widest sense of the term." Its pages will be open to all, official and non-official alike, for papers on subjects of research connected with medical and sanitary science. It is added that research work is rapidly developing in India, and Sir Harcourt Butler makes an earnest appeal to all who are interested in it to support the journal and enable it to hold a high place among the scientific journals of the world. The first number contains 16 articles dealing, amongst other things, with cholera, kala-azar, dysentery, latent malaria, &c. Photographic reproductions of certain biting insects are beautifully done. The journal, which is published by Messrs. Thacker, Spink, and Co., of Calcutta, is admirably printed on thick paper. Its price is six rupees per annum.

Hospital Accommodation in Cochin.

The Anglo-Indian community of Cochin, numbering over 3000, are making arrangements to memorialise the Madras Goverment, through the local municipal chairman, to reconsider its decision to omit the proposed European and Eurasian ward from the estimate of the new Municipal Hospital submitted by the local civil surgeon.

Infant Mortality in Bengal.

In the annual report of the Sanitary Commissioner for 1912, just published, it is stated that nearly 340,000 children under one year died in Bengal, representing a loss of 21 per cent. of the births. The figures for 1911 were just under 310,000. Calcutta has hitherto returned the highest infant death-rate—26 per cent. of births—but Jalpaiguri, with 28·69 per cent., and Dinajpur, with 26·26, are now worse. Cholera and fever have been prevalent, but infant mortality is not largely due to these diseases, but to ignorance of hygiene and want of skilled medical treatment.

Child Life in Calcutta.

A correspondent of a Calcutta paper draws attention to the fact that little children are employed in the city to descend the drains and clean them. The corporation should take the matter up and substitute more humane and up-to-date methods of cleaning the drains of the city.

The Drainage of Imperial Delhi.

The scheme for the training of the Jumna at Delhi is to be prepared in due course. The engineering difficulties are not likely to be great, and with the services available of experts in river training in India the work should be completed in two or three years. When once the Jumna has been "trained" it can be kept to channels that will leave the area now liable to flooding high and dry all the year round.

Ambulance Work in India.

General Haji Hafiz Obeidullah Khan, C.S.I., Imperial Service Lancers, has signified his intention of presenting an ambulance challenge shield to the Indian Council of the St. John Ambulance Association for competition among the units of the St. John Ambulance Brigade in India and Burma.

Tube Wells in India.

Experiments with tube wells in India are still being

carried out, and experience alone can show where they can be used with full advantage, but of their utility in some tracts there can be no question. In Vol. II. of the proceedings of the All-India Sanitary Conference at Madras a short paper by Mr. T. A. Miller Brownlie, municipal engineer of Amritsar, gives some particulars of borings and workings. His concluding paragraph is worth particular attention, for he says: "The question of the relative cost of tube wells is of no great importance when one considers that from an ordinary masonry well 12 feet in diameter, as built for modern water-supplies, the average yield is roughly 3000 gallons per hour and the cost is over £200; whereas at a less cost a tube well can be sunk which will yield 45,000 gallons per hour, or 15 times the supply of an ordinary well and under the same head." After such a statement we can fully agree with him that a considerable amount of good can be done by the installation of tube well water supplies for towns and villages of India which are in urgent need of pure water. It is to be hoped that experiments will be steadily continued and that the results gained will be made public.

Town Planning in India.

The Government of Madras has now taken steps to frame a set of rules, and has issued them for the guidance of municipal councils, to ensure that schemes for the extension of sites and the provision of house accommodation are carried out with regard to sanitary principles. Certain draft rules were first circulated amongst the various municipalities in the Presidency for their criticism. A large majority of the municipalities approved of the rules in their entirety, while several of them, like Coimbatore, Ellore, and Tanjore, made some excellent suggestions based on their own experience. The rules come into force on Oct. 1st in all except hill municipalities. All such undertakings have to receive the approval of the district medical and sanitary officer or the Sanitary Commissioner, with special reference to the suitability of the soil for building construction, facilities for drainage, water-supply, and other matters. Streets are required to be marked out on the sites, and as far as possible to run in straight lines crossing one another at right angles, and the main streets, exclusive of lateral drains, are to be not less than 40 feet, the secondary streets not less than 30 feet in width. All streets are to be metalled throughout their entire width, not merely in the centre of the roadway, and any departure from this rule is to be made only with the sanction of the Government. Conservancy lanes 10 feet in width, exclusive of lateral drains, must be formed along the backs of houses, and streets must be provided on both sides with open and impervious unshaped drains to carry off storm-water. The formation of streets and drains, it is wisely laid down, should form part of the scheme for laying out the sites, and should ordinarily be put in hand simultaneously with the execution of the scheme. In large streets the municipality will maintain suitable avenue trees on both sides of the street.

Efficient Medical Women.

The results of the examinations of the Agra Medical College seem to show that the women students are more efficient and more diligent than the men. Major E. J. C'Meara, I.M.S., in his annual report, states that 65 male students appeared at the final medical examination in April, 1913, and only 29 passed in all subjects. Out of 20 women students who presented themselves 13 passed in all subjects. Of the male failures 27 were remanded for one year and 9 were recommended for dismissal, as in the opinion of the Medical Board they are never likely to pass, and their retention is a waste of money to the Government.

Pasteur Institute for Burma.

In sanctioning the scheme for a Pasteur Institute in Burma the Secretary of State has been pleased to sanction the proposal put forward by the local Government that the balance of the grant of two lakhs by the Government of India for the purpose of erecting a bacteriological institute at Maymyo, part of which has already been devoted to the construction of a combined chemical and bacteriological laboratory at Rangoon, shall be applied to the provision of a small bacteriological and serological laboratory in connexion with the Pasteur Institute at Rangoon and the construction of quarters for the director.

Sept. 20th.

Obituary.

WILLIAM CARNEGIE BROWN, M.D., C.M. ABERD., M.R.C.P. LOND.,

PAST SECRETARY OF THE SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

THE death of Dr. W. Carnegie Brown has removed one who had done much to draw together the groups of individuals interested in the study of tropical medicine, owing to the important part which he took in the formation and development of the Society of Tropical Medicine and Hygiene, and at his funeral on Oct. 2nd the society was represented by Sir Ronald Ross, past president of the society; Dr. F. M. Sandwith, vice-president; Dr. T. P. Beddoes, and Dr. C. F. Harford, one of the present honorary secretaries. Dr. Sandwith also represented the London School of Tropical Medicine, and a wreath was sent by Sir Patrick Manson, the first president of the society.

William Carnegie Brown received his medical education mainly at Aberdeen, though he also studied at St. Thomas's Hospital. He took his M.B., C.M. Aberdeen in 1880, and after that saw something of life abroad by serving as medical officer of the White Star and P. and O. lines. In 1884 he took his M.D. degree, and from 1885 onwards he was medical practitioner in Penang, in the Straits Settlements. Here he gained good insight into tropical diseases, and, being a careful observer, made a study of some of the principal diseases that are met with in that part of the world. His chief contributions to the literature of tropical medicine, published since his return home, have been two books, one on "Sprue and its Treatment," which was published in 1908, and the other on "Amœbic Dysentery, its Complications and Treatment," published in 1910. Both of these books give a very good summary of the knowledge available concerning these two diseases at the time of writing, and it will be admitted that both these subjects are worthy of a good deal more consideration than has been generally accorded to them.

In the year 1904 he returned to England and took rooms in Harley-street, and at once associated himself with workers in tropical medicine. In 1906 he became a Member of the Royal College of Physicians of London, and in 1907, when a movement was started to found a new Society for the Study of Tropical Diseases, Dr. Carnegie Brown was chosen with Dr. Sandwith to be one of the honorary secretaries. By his tact and hard work he contributed largely to the success of the new society and gained the confidence of all his colleagues, and he continued to hold the post of secretary of the society until his health failed in the summer of 1912, when he felt obliged to resign his office. As a matter of fact, for some time previously he had been failing in health, but he stuck to his post with the greatest zeal, even though he did so at great cost to himself. The fact that there are at the present time 608 Fellows of the new society, although it has only been in existence six years, is the best monument to the indefatigable labours of Dr. Carnegie Brown. Many difficult questions came up for consideration by the society during his term of office, and nothing exercised him more keenly than the negotiations which took place between the Royal Society of Medicine and the Society of Tropical Medicine and Hygiene on the possibility of amalgamation. Dr. Carnegie Brown felt most keenly the seriousness of the problem, and he was of opinion that the cause of tropical medicine, represented as it was by medical men scattered throughout the world, needed a special society to represent its interests. He was not identified with any of the teaching schools, and therefore he could act in a specially disinterested manner, and this fact lent great value to his services. His good judgment in arranging the programme of the session and in securing papers from those best qualified to deal with particular subjects was most noticeable, and he has left behind him a record of patient and persevering work which cannot fail to act as a stimulus to his old colleagues and to all who remember him.

Dr. Carnegie Brown leaves a widow, three sons, and three daughters.

DAVID MOUNT HUTTON, B.Sc., M.D., C.M. EDIN.

BORN in Liverpool of Scottish parents 43 years ago, David Mount Hutton received his primary education at preparatory schools in St. Andrews and Edinburgh, and with a sound equipment in literature, classical, English, and German began professional study at the Edinburgh University, first in science, in which he graduated B.Sc. in 1892, and thereafter in medicine proper, taking the M.B. and C.M. degrees in 1895, and finally the "summi in medicinâ honores" with honours in 1899.

So qualified, he entered immediately on general practice at Southport-cum-Birkdale and rapidly acquired the confidence of a large *clientèle*, thanks to the very thorough clinical training he had undergone as resident physician in the Edinburgh Infirmary, and also as physician in the Royal Children's Hospital in the same school. In quick succession he became medical referee to the Scottish Provident among other insurance companies, Fellow of the Royal Society of Medicine, and an active member of the North of England Obstetrical and Gynæcological Association, as also of the Society for the Study of Children's Diseases. Latterly, amid much strenuous professional work, he interested himself in the movement, now progressing under Government auspices, for the Care of the Feeble-minded, aiding it effectively on the platform and in the press, while acting as President of the Southport Branch of the Lancashire and Cheshire Society organised in the same philanthropic interest. He even found time for enriching the literature of the profession by articles such as that on Myiasis, published in the "Encyclopædia of Medicine"; on a Case of Syphilis Transmitted to the Third Generation, printed in the Transactions of the Society for the Study of Children's Diseases; on Accidental Parasitism of Dipterous Larvæ in the Human Body, contributed to the Liverpool Medical Society's Journal; on Some Therapeutic Applications of Chloretone; and on the theme he had made peculiarly his own, the Care and Control of the Feeble-minded—a very favourably received paper published in the "Special Schools Quarterly."

Fifteen years of such work, rarely and never adequately relieved by respite or holiday, began, however, to tell on a constitution in the main robust, but not proof against the handicap of an anxious temperament and a sense of duty that never spared itself. Premature breakdown became more than ominous, insomuch that preparations were on foot for a six months' *villeggiatura* in Italy. But—*Dis aliter visum*. The project indeed had barely been initiated under a medical friend's roof near London, when suddenly, if not quite unexpectedly, he succumbed to heart failure on Sept. 21st. "And so," writes a valued correspondent of THE LANCET who knew Dr. Hutton intimately, "there went down while it was yet day' the 'sun' of a guileless and generous nature which, devoted—mind and soul—to the medical calling, 'knew its art but not its trade,' finding its true honorarium in the gratitude it earned not only by the skill acquired in the schools but by the *sagacité de cœur*, which is the precious, the distinctive possession of the born physician."

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. A. van der Loeff, formerly inspector of the medical service in West North Brabant and Zeeland, aged 71.—Dr. P. Alt, privy sanitary councillor of Charlottenburg.—Dr. F. Deus, sanitary councillor of Berlin.—Dr. A. Pitschpatsch, sanitary councillor of Sagan.—Dr. A. Thorwith, sanitary councillor of Berlin.—Dr. Julius Preuss, of Berlin, whose contributions to the press on the subject of Jewish medicine in history are of great and universal interest. His latest work, which includes most of his previous researches, was "Biblisch-talmudische Medizin." His age was 52, and he held the rank of sanitary councillor.—Dr. Theodore S. E. Schaepkens van Riempst, lecturer on genito-urinary diseases in the New York Polyclinic Medical School and Hospital.—Dr. John P. Pardue, formerly professor of materia medica and hygiene in the St. Louis College of Physicians and Surgeons.—Professor Robert Kutner, director of the Kaiserin Friedrich Haus, Berlin, and general secretary of the International Committee for Post-graduate Medical Education.

Correspondence.

"Audi alteram partem."

THE PATHOLOGY OF THE CONDITION KNOWN AS PARASYPHILIS.

To the Editor of THE LANCET.

SIR,—The extremely interesting and highly scientific paper by Dr. J. McIntosh and Dr. P. Fildes in THE LANCET of Sept. 27th tempts me to write a brief note on the subject as it presents itself to one who has had a certain amount of clinical experience and training, but very little experience of, or training in, modern precise methods of microscopical and biochemical research.

I would first mention three small items of great interest to myself, and of what I consider great clinical importance. The first one is a statement made by the late Sir Jonathan Hutchinson when teaching a class of students of whom I was one. He said that he had watched a patient for many years whose sole indication of tabes dorsalis when first seen was the absence of knee-jerks. He had, in the course of time, developed the other classical features and had ultimately died from progressive nerve trouble. I had then, and have not now, any reason to doubt his statement.

The second item is a fragment of a conversation I held some seven or eight years ago with my late colleague, Harold Barnard, who said to me, "Smith, what is your rule and teaching about administering mercury to patients suffering from disease and whom you suspect to have had syphilis at some previous period upon which the present symptoms may possibly depend?" I replied very promptly, "I teach and practise that in all such cases mercury should be very freely and promptly administered, and that iodides might also be given, but mercury never under any circumstances omitted." "How do you give mercury?" he asked, and my reply was, "Invariably by inunction of the ung. hydrarg. of the B.P." I have seen no reason to depart from my teaching or to alter my rule.

The third item is a case from my private practice. In November, 1895, I was asked by Dr. J. J. Coulton to see a patient then aged 33, who had acquired syphilis "in the year of the Paris Exhibition." (So my note runs. I have no reference by me to fix what this year was.) Subsequently, he had suffered from gumma of the testicle, but "all seems to have cleared up," and he was well till three days previous to my first consultation, when he was suddenly seized with aphasia and amnesia, could not write at all properly, began words and could not finish them, used wrong words, &c.; these symptoms had improved under K.I., with which his medical man had treated him. I have a few more notes on his nervous system, but they are not very material. I heard in March, 1896, that he had got quite well after three months of mercurial treatment combined with potass. iod. In October, 1897—i.e., nearly two years later—I saw him again with some acute illness which at the time I thought was typhoid fever, but as he had some nervous symptoms (slow syllabic speech, mind far from clear, &c.) which did not seem to be accounted for by typhoid fever, I ordered ung. hydrarg. to be rubbed in. I saw him again a fortnight later, and my note runs: "No doubt now about G.P.I. He has been made Lord S. and has acted in Germany at £1000 a night, and has £250,000; the only thing is his pupils react readily to light, but then they oscillate. His speech is very drawly and characteristic." By Nov. 10th he had had 30 inunctions of mercury; had quite lost his delusions. "His lips and speech are very characteristic of G.P.I. and his knee-jerks are greatly exaggerated; his pupils react steadily to L. and A." By December, 1897, quite sound in mind. K.J. ++. Pupils react fairly, but not absolutely as they ought to do. In 1898 he came to me to ask advice as to the frequency with which he ought to indulge in sexual connexion; desire and power both in excess. In 1899 my note runs: "Feels very well. Hands quite steady; mentally clear; good head for business. K.J. natural and equal; pupils react readily to L.; tongue quite steady." In 1901: "A bit below par. K.J. slightly glib. Pupils react readily to L. and A." In 1906: "Health excellent. K.J. both fairly free." I have not seen the patient since then, so that he may have died in the interval, and that, too, from G.P.I.

I leave these items for a moment to mention the views that I adopted in my student days and taught when I reached a position of responsibility to students and still teach—viz., that if parasyphilitic had any meaning at all it was intended to convey the idea that active syphilisation had ceased, but before ceasing had produced such disturbing effects upon lymph- and blood-vessels as to diminish the food-supply to, and removal of waste products from, the nerve fibres or cells to such an extent that the cells, and therefore the fibrils dependent on the cells, slowly but surely, and usually progressively, perished. All this seemed to me a legitimate deduction from what was then known of the power of syphilis to produce what was termed syphilitic endarteritis—a process that resulted in diminishing the calibre of the vessel below its optimum. I had then no suspicion that the microbe of syphilis could still be alive, and could be continuing to produce toxins having a primary deleterious action upon nerve cells.

It would make my comments too long to pass in review, as Dr. McIntosh and Dr. Fildes have so ably done, the various stages in the controversy regarding parasyphilis, but I would like to contradict flatly, by my own experience, the statement that "the result of treatment is *nil*." Your authors dispute the statement, and my experience confirms their view, but there must, of course, be added the proviso that treatment by mercury must be undertaken early, and often, indeed, while the evidence of syphilis is still doubtful. (I do not wish here to enter upon the value and importance of the Wassermann reaction, because I hold the view that mercury is useful in other conditions than syphilis, and therefore treatment can do no harm and may be of immense good even if syphilis be not a factor in the trouble.)

I would like to ask Dr. McIntosh and Dr. Fildes for a critical consideration of my case mentioned above; to call it a "particularly toxic secondary encephalitis," and to refuse it the name of "early general paralysis" seems to be somewhat of an anomaly.

I would like, Sir, in conclusion, to ask them also whether I am correct in saying that the most elaborate investigations of modern research do not contradict in any essential particular my view of what one ought to teach students. By essential I mean affecting the chances of the patient's cure. Or would they urge me to wait for the results of a Wassermann before resorting to mercury? (I do not wish to enter into any controversy as to the relative merits of mercury and neosalvarsan for the cases I am considering.) It seems to me that modern pathology rather supplies a firm basis of ascertained facts for my practice, a position of affairs which naturally gives me great satisfaction; and I shall conclude that it is never, clinically speaking, too late to apply antisyphilitic treatment.

I am, Sir, yours faithfully,

F. J. SMITH, M.D.Oxon.,
Physician to the London Hospital.

Harley-street, W., Oct. 2nd, 1913.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Sept. 27th you printed a contribution from us entitled "The Pathology of the Condition known as Parasyphilis." In this paper we put forward the view that dementia paralytica was merely the expression of tertiary syphilis of the brain. The condition differed from the gummatous processes confined more or less to the lymph vascular tissues, in involving chiefly or entirely the nervous substance proper. The wide extent of the lesion resulting from a minimal number of spirochætæ was due to the fact that the patient was in a "tertiary" condition—in other words, because his tissues were hyperimmune (hyperallergic) to the virus. Acute encephalitis was a lesion pathologically similar, but since its onset was relatively early after infection the tissues had not become hyperimmune, and thus a marked spirochætosis produced relatively little reaction and destruction.

We wish now to mention that Professor Noguchi, in the current number of *La Presse Médicale* (Oct. 4th), demonstrates that normal rabbits are insusceptible to intracerebral inoculations of spirochæta pallida. If, however, the animal is sensitised by repeated intravenous injections of spirochæta pallida, an intracerebral inoculation will then produce the lesion of dementia paralytica. Noguchi's investigations appear to supply the experimental evidence which is at present lacking in our purely inferential study.

We are, Sir, yours faithfully,

JAMES MCINTOSH.
PAUL FILDES.

London Hospital, Oct. 6th, 1913.

THE NATIONAL INSURANCE ACT: THE APPOINTMENT OF MEDICAL REFEREES.

To the Editor of THE LANCET.

SIR,—Medical men of all ranks are frequently asked by insurance offices or employers to examine claimants who allege that they are suffering from either accident or disease, and it is one of the settled ethical laws which govern the profession that, knowingly, no medical man shall examine the patient of another medical man except in consultation or after having first obtained his consent.

House surgeons and general practitioners continually meet medical examiners acting for insurance offices, but they decline to do so unless they are paid the usual consultation fee of £1 1*s*. The most recently qualified house surgeon will decline to attend a consultation or to write a report under the fee of £1 1*s*. General practitioners all over the country receive the same fee, if not more, for their loss of time, care, and responsibility, when called upon to give at a consultation a detailed history of a case. The Home Secretary, in fixing the fees of medical referees under the Workmen's Compensation Act, fixed a fee of £2 2*s*. as the fee for a medical examination and report to a county court judge, and no one has ever hinted that this sum is excessive.

Bearing in mind the above facts, the question arises as to what should be the attitude of the profession in regard to the appointments of medical referees by Local Insurance Committees, either at small salaries or at fees hitherto unheard of for the class of work required and without any published regulations safeguarding the ethics of the profession.

The London Insurance Committee have appointed six medical referees for the county of London, and these practitioners have presumably agreed to make visits, hold consultations with panel doctors, and write reports for the information of the Insurance Committee at an inclusive fee of 7*s*. 6*d*. per case, on which reports the standing, knowledge, and experience of the panel doctor are to be adjudicated on by the committee, as is also the character of the insured persons whose *bona fides* is in question. These latter persons will be at the mercy of an Insurance Committee solely dependent for its information on the report of a medical referee, and they may be branded as malingerers or exaggerators by the committee in a manner which may affect their whole future lives.

Six medical practitioners have accepted this enormous responsibility at a remuneration of 7*s*. 6*d*. for each consultation, examination, and full report, and it seems most improbable that any of these gentlemen, who have accepted these appointments, have realised their onerous and responsible nature or the time that must be given to each report if justice is to be done to the parties interested, or that they have satisfied themselves that regulations have been made for the obtaining in each case from the panel doctor in charge a full and exhaustive history at a consultation to be attended by the panel doctor, on terms satisfactory to himself and the profession.

If such regulations have been made the profession has a right to ask that they may be published in the medical press, so that every medical man on a panel may know exactly how he stands under the regulations, having regard to the ethics of the profession. It may be that medical referees appointed by the Insurance Committee are merely intended to advise in the first instance on a short form, but even if so, and if there is to be a right of appeal either to the Insurance Commissioners or to medical referees appointed by the Commissioners under the powers they hold under the National Insurance Act, yet even then it is most essential that the reports of medical referees to the Local Insurance Committee should be thoroughly well considered and written

under a due sense of responsibility. It is generally understood that after the report of the Departmental Committee now sitting the whole question of medical referees, both under the National Insurance Act and the Workmen's Compensation Act, will be carefully considered, and no doubt the following three questions will be kept in view: (1) Whether the decisions of medical referees shall be as now, "final and conclusive," or whether they shall be subject to appeal; (2) whether they shall be whole-time officers or part-time, payable by fees, as at present; and (3) whether a simplification of procedure and a saving of expense could not be effected by the appointment of one body of medical referees to examine and report under both the Workmen's Compensation Act and the National Insurance Act.

It will be generally felt that with a more extended use of medical referees, especially if their decisions are to be "final and conclusive" and if they are to have the confidence of the profession, they should be men of ripe experience, not only in the various kinds of medical practice, but especially in the examination of persons claiming to be incapacitated by either accident or disease, and that they should be men of tact, well used to meeting every kind of medical practitioner in consultation.

I am, Sir, yours faithfully,

South Hampstead, N.W., Oct. 4th, 1913. ALBERT BENTHALL.

THE DISCOVERY OF THE RADIUM-MESOTHORIUM CURE OF CHRONIC DEAFNESS OF THE HOPELESS KIND.

To the Editor of THE LANCET.

SIR,—Among the seriously inaccurate statements that have quite recently been made in the lay press in regard to treatment by radium and radio-active agencies that alleged to have emanated from the "Medezenalen Klinik" in which Dr. Hugel, of Berlin, is credited with having discovered the curative effects of radium and mesothorium in chronic deafness, is one that cannot be allowed to pass unchallenged.

Having in October, 1908, observed and realised the curative effect of what I had provisionally termed the "ultra-X rays" in a cast of chronic deafness in a hospital out-patient, who was being treated under my directions for specific gummata of the tongue, obliquely through the open mouth, a second case that had been otologically examined and given up as hopeless, being that of an acquired deaf-mute, was experimentally subjected to a similar course of "ultra-X ray" treatment with very satisfactory results. Both cases were subsequently exhibited at the hospital clinical meetings, and were duly published.

As two such exceptional experiences were not sufficiently conclusive they were subjected to the test of time, and the experiments were repeated in a few similarly hopeless deaf cases in 1909. During this year I also began to treat some with a plaque of radium bromide which I fixed over the mastoid process, and later the radio-active mineral autunite was introduced into the meatus in 1 centigramme metal capsules. In April, 1910, I brought forward two of the originally deaf patients before the Neurological Section of the Royal Society of Medicine, in order to illustrate what I then termed the neurogenetic effect or amœboidism induced by these radiations in nerve terminals. Owing to the large number of cases that were exhibited on that occasion the exhibition of mine was unavoidably deferred.

This experimental research was, however, continued without intermission in spite of the obstacles that presented themselves. By August, 1912, having had a large and convincing experience, I submitted the notes of a few of these cases to THE LANCET. The Editor courteously replied in returning my notes, and suggested that my cases had better be exhibited and discussed at one of the medical societies before publication. Accordingly, in November, 1912, the notes of my eight earliest cases (five of which were originally deaf-mutes) were submitted to the president of the Otological Section of the Royal Society of Medicine. After a few days he expressed his interest in the notes and kindly offered to introduce me to the meeting when the time arrived. Not being an otologist or a member of that section, I was informed that the notes would first have the consideration of the council before a date could be fixed for their discussion. This date was finally fixed for Feb. 21st, 1913, three months later.

At the eleventh hour, however, after the circulation of the notes on the agenda paper of the meeting, certain of the members of that section raised a protest to the president, threatening to resign and form another otological society if my cases were examined or discussed. The president, under these circumstances, reluctantly complied with their demands, and I was requested to cancel by wire my invitations to my patients, but this I could not bring myself to do; the patients were there, also a few medical men concerned in them, but they were not examined or discussed, to the consternation of many. I had the honour, however, of introducing some to the president.

Since this incident in the research that matter has been in the hands of my legal advisers. The experiments were continued, and in June last, at the invitation of the British Otolaryngological Society, I was able to exhibit four further cases that had been otologically tested both before and after a four months' course of treatment. A report was published in THE LANCET of July 26th last at p. 223, which speaks for itself. For this kind aid I desire to thank the Fellows of this society.

As the identical relationship of the radiations emanating from radium and mesothorium with those from such a Crookes's tube to the discharges from which I have provisionally applied the term "ultra-X" to may be questioned by some practitioners, permit me to describe that association briefly. Radium and mesothorium are elements both of which discharge the long beta and the gamma radiations, the "surpenetrans" of Dominici, but the enclosing metal or filter that is used to cut off the inevitable short radiations that damage the skin structures has, set up within the molecules of the metal, new secondary radiations of short length, the action of which has also to be provided against by more dense covering, other factors need not here be mentioned. A Crookes's tube that becomes useless for superficial therapeutic purposes, after repeated regenerations, the vacuum being now very high, it ceases to discharge the short radiations, though the long beta and gamma radiations continue to be discharged for some time longer with proper management, while using a heavy current and a spark-gap of from 10 to 12 inches. At this stage there is no difference therapeutically between these types of radiations from the sources under consideration. There is no primary necessity for protecting the skin from the action of these ultra-X rays. No metal filter being applied to the skin, there are no secondary radiations generated at the skin. An aluminium filter or thick leather disc is used in the path of the rays, at some distance from the skin surface, as a precaution against the occasional softening of the tube by heat at the anode when the cooling device fails. This valuable deep therapeutic feature of a high Crookes tube has not been known to medical science hitherto.

I am anxious to invite discussion which may help us nearer to the truth which we are all seeking.

I am, Sir, yours faithfully,

Gloucester-place, W., Oct. 7th, 1913. H. D. MCCULLOCH.

AURICULAR FLUTTER.

To the Editor of THE LANCET.

SIR,—I have read with much interest Dr. J. Hay's narrative of two cases of auricular flutter in your issue of Oct. 4th, but my object in writing you on this occasion is not to offer any comment on the suggestions it contains either as to the nature or treatment of that condition. To do so satisfactorily would require more space than you might feel disposed to grant and involve discussion more suited to a longer article. The subject, however, is one of increasing interest, and a considerable number of cases of the condition in question have now been observed—30 in all, according to Dr. W. T. Ritchie in his valuable article just published in the *Quarterly Journal of Medicine*. For personal reasons I have some reluctance in troubling you even with the note I am about to write, but statements of fact, however pardonably erroneous, are apt to become stereotyped if left uncorrected.

The first case of non-drug auricular tachycardia recorded

was one mentioned by myself in an address given in October, 1908, and published in THE LANCET of Jan. 9th, 1909. It was under my care in the Great Northern Central Hospital in 1903, and was associated with audibility of the extra auricular systoles as well as with their reproducibility by the graphic method.

Dr. Ritchie recorded a high rate of auricular pulsation still earlier[1] in a case of ventricular bradycardia, but the auricular speed in that case followed the administration of atropin, and he refers in his last paper to another case published by the late Dr. G. A. Gibson. These observations were all made prior to those on the interesting and important case recorded by Dr. Herz and Dr. Goodhart in January, 1909, not in 1908, as stated in Dr. Hay's paper.

Dr. Ritchie mentions that in his atropised case of accelerated auricle no auricular sounds were heard. The audibility of the sounds in my case, which I described to the Æsculapian Society on Dec 13th, 1908, as "jugular embryocardia,"[2] was probably owing to the comparatively slow rate of the massed rhythmic auricular extra systoles, as I consider them to be, in spontaneous cases and to their force. The auriculo-ventricular ratio was as 2 to 1. The higher the auricular rate and the more nearly the pulsations approach the impotence of auricular fibrillation, into which they may apparently at times pass, the less audible in all probability are the auricular sounds likely to be.

I am, Sir, yours faithfully,
ALEXANDER MORISON.

Upper Berkeley-street, W., Oct. 6th, 1913.

LOW-PRICED CLINICAL THERMOMETERS.

To the Editor of THE LANCET.

SIR,—The variations in the readings of the thermometers described by Dr. J. B. Cook in his letter in your issue of Oct. 4th are not necessarily indications of faulty instruments. It is possible to immerse a dozen quite reliable instruments in warm water and obtain as many different readings. In performing the test, among other precautions to be observed one should ascertain that the thermometers have been well "shaken down," that the water is maintained at a constant uniform temperature, and that the instruments do not touch the bottom or sides of the vessel. Of the many dozens of clinical thermometers examined here the percentage of rejections is very small indeed, and the greatest error observed has not exceeded one degree.

The price of 10*s.* 6*d.* per dozen cannot be described as cheap, for accurate 2 min. and ½ min. thermometers can be purchased from makers at far less than 10½*d.* each, while 1 min. thermometers fitted with a lens front and verified at Kew are obtainable at less than 2*s.* each. Dr. Cook does not state whether he ascertained the behaviour of the thermometers when used to take the temperature of the body.

I am, Sir, yours faithfully,
F. A. HOCKING,
Pharmaceutist to the London Hospital.

Oct. 4th, 1913.

DISTRIBUTION OF INSURED PERSONS UNDER THE CAPITATION SYSTEM.

To the Editor of THE LANCET.

SIR,—In your report of the last meeting of the London Insurance Committee you mentioned that Mr. E. B. Turner rose to correct my statement as to the Manchester scheme. I have this morning received a letter from Dr. J. H. Taylor, of Salford, and with his permission I venture to ask you to print the following extracts from that letter :—

I notice that according to the *B.M.J.* supplement, p. 286, Mr. Turner says you were in error about the Manchester scheme. As a matter of fact, it is he who is altogether wrong. We have a panel in Manchester and Salford in every sense of the word and as defined in Regulation 7. All the doctors on the list had to sign an agreement conforming to the Act and Regulations and the conditions of the Parliamentary grant, and the Commissioners refer to us as the panel. It is quite true that the Local Medical Committees do not like the word panel, and so they use the word "list," but it is a sort of *placebo* which they use with a nod and a wink.

Again, Mr. Turner said that the Manchester Insurance Committee handed over the whole of the Medical Benefit Fund to the Local Medical Committee. If he meant exactly what he said it is another pious delusion like the first, which he may have heard in Manchester. Your own statement was far more correct than his. What really happens is as follows, and I speak with certainty here as a member of the Salford Insurance Committee appointed by the Commissioners. The system in Manchester is a copy of the Salford system, and in neither case is a single farthing handed over to the Local Medical Committee. The whole Medical Benefit Fund, that is 8*s.* 6*d.* per insured person (*less* a few contributions to persons receiving treatment through institutions and to persons making their own arrangements, who are very few in number), is divided up into three funds—13/17ths going to the panel fund, 3/17ths to the drug fund, and 1/17th to the drug suspense fund. To the panel fund is then added 6*d.* per person for domiciliary treatment of tuberculosis, which forms the medical treatment pool out of which the doctors are paid per attendance. The important point is that the whole of this pool is paid to the doctors, except that at each payment-on-account a very small sum has been kept in hand by the Insurance Committee, partly because a number of the doctors neglect to send in their accounts in time, and partly because it is impossible to tell beforehand the exact total for the year owing to the variation in the total number of the insured, and thus with payment-on-account in advance something must be kept in hand, but the amount is quite insignificant, and at the end of the year the full total will be distributed. In Salford only £61 was retained in hand on July 31st out of a total pool that will certainly be over £28,000 for the year. Practically, then, you were quite correct in saying that the whole fund available for medical treatment of the whole of the insured is paid to the doctors. Of course you know that the doctors have no lists as you have with your capitation system. We know nothing of the insured until they actually come to us for treatment, and they are allowed to go to any doctor, changing from one doctor to another as they like, Regulation 18 not being enforced. This, by the way, tends to increase the malingering, because if one doctor refuses a certificate the person simply goes about till he can find some other doctor ready to give a certificate. It is somewhat farcical for Mr. Turner to say that the money is handed over to the Local Medical Committee. All that committee does is to scrutinise the doctors' bills, and it has the power, which is often used, to cut down any doctor's bill when his attendances have been above the average, as excessive attendances would, of course, unfairly deplete the pool. When the bills have thus been checked they are sent to the clerk of the Insurance Committee, who again checks them to see that none but insured persons have been included, and the clerk then presents them to the Insurance Committee, which may pass them for payment. Of course, the Local Medical Committee has nothing to do with the drug fund. Up to the present the whole pool has only sufficed to pay the doctors about 60 per cent. of their bills charged according to a scale of fees agreed on between the Insurance Committee and the Local Medical Committee, but this small dividend is solely because of the large number of attendances, the insignificant sum kept in hand by the Insurance Committee making no practical difference. You will see that on our system we avoid your difficulty of unallotted funds, but we have what is to my mind a far worse difficulty—namely, that payment by attendance encourages each doctor to put in as many attendances as possible.

The matter is one of considerable importance, but Dr. Taylor has stated the case clearly, and I think no comment is needed to show that the misunderstanding as to the system of payment in Manchester was Mr. Turner's, not mine.

I am, Sir, yours faithfully,
H. H. MILLS.

THE MEDALS OF THE INTERNATIONAL MEDICAL CONGRESS.

To the Editor of THE LANCET.

SIR,—In the confusion of the Congress a box of Congress medals was lost. It may be that on this account some members of Congress or ladies may have failed to obtain them. If such persons will write to me the medals will be sent to them.

I am, Sir, yours faithfully,
W. P. HERRINGHAM,
Honorary General Secretary.

40, Wimpole-street, W., Oct. 4th, 1913.

MEDICAL MAYOR. — Mr. R. Jones Evans, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed mayor-elect for Pwllheli.

UNIVERSITY OF LONDON : UNIVERSITY COLLEGE.—In connexion with the Faculty of Medical Sciences at University College, London, the following awards have been made :—Bucknill Scholarship (135 guineas) and First Medical Exhibition (55 guineas), divided equally between M. H. Oldershaw, of the Brighton Municipal Technical College and University College, London, and D. J. Thomas, of St. David's College School, Lampeter, and University College of Wales, Aberystwyth. W. Feldman, of the Central Foundation School and University College, London, is classed as second medical exhibitioner (without emoluments). Epsom Free Medical Scholarship: E. V. Corry.—The Goldsmid entrance exhibitions have been awarded as follows :—First exhibition: T. H. Somervell, Caius College, Cambridge. Second exhibition: J. Vincent Bates, Pembroke College, Cambridge. Proxime accessit: G. Y. Oliver, University College, London.

THE NATIONAL INSURANCE ACT.

SANATORIUM BENEFITS IN BIRMINGHAM.

A REPORT on the administration of sanatorium benefits for the year ending July 14th last has been issued by the Birmingham Insurance Committee. In consequence of the policy adopted by the city council it was possible to make early arrangements for the treatment of insured patients at the sanatoriums provided by the council. The first patient was admitted on August 24th, 1912, and a provisional scheme remained in force until July 14th of this year. The Local Insurance Committee has now entered into an agreement with the Birmingham corporation for a period of 30 years under which the corporation will provide the whole of the institutional treatment of insured persons suffering from tuberculosis, recommended by the committee, within the limits of the accommodation and facilities provided by the corporation's scheme for insured and non-insured persons, which when in full operation will include the following accommodation—viz., residential institutions (available for insured and non-insured persons): Yardley-road Sanatorium (including 50 beds reserved for children), 199 beds; Salterley Grange Sanatorium, 68 beds; West Heath Sanatorium, 52 beds; Romsley Hill Sanatorium, 100 beds provided by the Hospital Saturday committee, the corporation having arranged for the use of 90 beds. Dispensary accommodation is provided at the Broad-street Tuberculosis Dispensary for 2000 patients per week.

The treatment provided in the sanatoriums has been very widely appreciated, and the conduct of patients has been generally satisfactory. It has been necessary to expel a few owing to non-observance of rules, but all cases of expulsion have been investigated by the Committee and arrangements made for the patients to continue treatment in some other form, either dispensary or domiciliary. Fifty-eight patients neglected or declined to take advantage of sanatorium treatment, and 31 refused the dispensary treatment recommended. In some cases the reason given was the necessity to continue work in order to obtain means of subsistence for the family. In other cases treatment was declined because patients felt much better in health than when the application was made, and state that they will apply again if their condition changes. 1783 applications for sanatorium benefit were received, of which 1102 were from males and 681 from females. Of these 63 males and 58 females were ineligible on grounds other than health. Of the 1039 males referred by the Committee to the medical adviser for examination, 908 were members of Approved Societies, as were also 527 of the 623 females. During the year 834 males and 533 females were examined, 68 males and 20 females failed to attend for examination, and 137 males and 70 females were awaiting examination at the close of the year. Sanatorium treatment was recommended to 551 males and 347 females—337 males and 206 females to a course of six weeks; while 182 males and 152 females were ordered dispensary treatment. Domiciliary visits were suggested for 89 males and 31 females.

A table shows the occupational incidence of pulmonary tuberculosis, from which it appears the engineers sent the greatest number for treatment—this being 130 males and 18 females; while 104 general labourers were included. There are 103 domestic servants (including charwomen), 66 female press-workers, 43 warehouse workers and 36 clerks on the female side. The residential incidence varies from 3·9 per 1000 in St. Bartholomew's ward to 0·2 in North Erdington. The average for the whole city is 1·9 per 1000. The income for the year was £12,697 9*s.* 7*d.* and the expenditure £11,849 12*s.* 6*d.*, divided as follows: maintenance at sanatoriums, £6267 17*s.*; dispensary, £1142 15*s.* 6*d.*; domiciliary (estimated), £3622 10*s.* 3*d.*; medical examinations, £393; administration expenses, £350; incidentals, £73 9*s.* 9*d.*

THE MEDICAL PROFESSION IN GLOUCESTER AND MEDICAL AID ASSOCIATIONS.

At the recent quarterly meeting of the governors of the Gloucester Royal Infirmary and Eye Institution the following resolution passed by the honorary medical and surgical staff and forwarded to the general committee was read:—

That the medical staff having been appealed to by the medical men practising in the Forest of Dean and other parts of Gloucestershire to support them in their endeavour to secure adequate remuneration for contract practices, have decided that in the case of any medical aid associations having for their object the employment of medical men under conditions not approved of by the medical profession they will not, under any circumstances, meet in consultation or have professional dealings with any medical man holding office under any such association, either in the case of a private patient or at the Royal Infirmary, and they must therefore decline to treat members of such associations except in those cases urgently requiring hospital treatment.

Two other resolutions explanatory of the situation were also read. The first, which had been passed by the Gloucestershire branch of the British Medical Association, was to the effect that medical aid associations having been established in certain areas since the passing of the National Insurance Act, and having been sanctioned by the Medical Benefit Subcommittee, such action was to be deemed inimical to the interests of the medical profession and constituted a breach of faith on the part of the insurance authorities. The branch therefore called upon the staffs of the Gloucestershire hospitals to refuse to recognise professionally those holding appointments in such associations, or to treat members of them except in circumstances of great emergency. The second resolution passed at a meeting of medical men practising in the city of Gloucester was as follows:—

That this meeting of medical men in practice in the city of Gloucester considers the manner in which medical aid associations carry on their work as injurious to the interests of their patients and unfair to the doctors, and decides to refuse to recognise the staffs connected with these institutions. This meeting calls upon the staffs of all the hospitals in Gloucestershire to refuse treatment to medical aid patients except in cases of great gravity.

It is stated that the two last-mentioned resolutions have been signed by every member of the medical profession practising in the city of Gloucester.

HOSPITALS AND INSURED PATIENTS.

It is a matter of importance to hospitals, and particularly to those to the funds of which working men have been regular subscribers, that the circumstances in which, and the extent to which, insured patients are refused treatment at a particular institution should be made as clear as possible. The statement that insured persons will not be treated at a hospital is one easily made or repeated by a careless hearer without the necessary reservations, and so the story may gain ground that in no circumstances will any hospital treatment be given to a person who is insured. The usual proceeding is that all cases requiring immediate attention, as, for example, accidents, or such special treatment as only a hospital can give, will be treated, but that the hospital staff will not do for nothing that which medical men on the panel are receiving money to do. Attention has been called to this point recently at Cheltenham, and to the loss of income to which a hospital may be subjected by a misunderstanding which is excusable, but which can be removed by the proper explanation being given.

THE ALLOCATION OF INSURED PERSONS NOT MAKING THEIR CHOICE.

The question of the disposal of funds in the hands of Insurance Committees through insured persons not having chosen a medical man on the panel to attend them, and not having been distributed as the Act provides, and generall the question as to how their distribution is to be arranged for, have been occupying the attention of many committees besides that of London, including those of Cheshire, Surrey, Derbyshire, and the East Riding of Yorkshire. In the last-named district the patients who have not chosen their medical men appear to have been already distributed, but we understand that this has been done recently, and do not draw the conclusion that the difficulty which has arisen in London has been entirely avoided in the East Riding. Apparently this difficulty, which has been emphasised by the opinion obtained in London from Mr. Danckwerts, K.C., has not been before the Provincial Insurance Committees referred to, but they will now have had their attention drawn to it. The method proposed to be adopted by any committee for the assignment of insured persons to practitioners on the panel, where no choice has been made by those persons, is one of those matters which has to be submitted to the Insurance Commissioners for approval. The plan followed in the East Riding, where the Local Medical Committee was consulted, has been to assign the patients to a given medical man as far as possible in numbers bearing

the same proportion to the total number of persons to be so assigned, that the number on his list bears to the total of the insured persons who have made their choice.

MATERNITY BENEFIT AND A PROSECUTION.

The first prosecution under Section 19 of the National Insurance Act for neglect on the part of the husband to make adequate provision for his wife during and immediately after her confinement, after receiving maternity benefit, has taken place at St. Helens at the instance of the Cheshire Miners' Permanent Relief Society. The defendant received the money, gave his wife 2*s.* only, and was found lying drunk on her bed; the midwife had to buy milk for the patient and the relieving officer was called in. The defendant received a sentence of 14 days' hard labour, attention being called by the case to the provision in the section of imprisonment up to a month with or without hard labour, but without the option of a fine.

THE NUMBER OF INSURED PATIENTS TO BE ACCEPTED.

The Birkenhead Insurance Committee discussed recently the question of the number of insured patients that a medical practitioner should have on his lists. The general feeling, in the expression of which medical members of the committee took a prominent part, was that there was considerable danger of work being inadequately performed where private practice was undertaken in addition to 1500 or 2000 panel patients, the amount of private practice being an important factor. A motion was carried that the matter should be referred to the Medical Benefit Subcommittee to report upon, the chairman of the committee saying in introducing it that it would be well to know the views of the Local Medical Committee on the subject, and suggesting 2000 as a number which ought not as a rule to be exceeded. The question whether to impose a restriction might involve interference with the right of the insured to choose their doctors, he answered by saying that it was the duty of the committee to see that the insured had adequate attention, and that he had heard complaints made that insufficient attention was sometimes given.

CHANGE OF DOCTOR.

The period is approaching when patients who put themselves on the lists of those medical men who joined the panels early will find themselves able to exercise their right to select another medical attendant should they so desire, and owing to accessions to the panels will also find their range of selection enlarged. Notice has to be given in the case of desired change a month before the expiration of the existing period. It is, we fear, inevitable that it should be felt a hardship by medical men who have come late upon the panels when their former patients having the opportunity do not return to them. Equally the medical man who accepted promptly the situation created by the Act is likely to feel aggrieved when patients leave him for latecomers on the panel. It is to be hoped, however, that resentment or friction, if any arises, will be shortlived. The choice, in any case, will be that of the patient, and it has been the contention of the medical profession throughout that he should be free to exercise it.

THE BRISTOL BOARD OF GUARDIANS AND THE NATIONAL INSURANCE ACT.

At the last meeting of the Bristol board of guardians a resolution was moved to the effect that in future it should be obligatory on all officers appointed to the workhouses that they should be "on the panel" of the resident medical officer. A considerable discussion took place upon the matter, and it was stated that the motion was contrary to the provisions of the Act, which provided that insured persons should have the right under all conditions to select their own medical attendant. Eventually the proposal was defeated, on a division, by 7 votes.

ROYAL MICROSCOPICAL SOCIETY.—The next meeting of this society will take the form of a conversazione at King's College, Strand, on Wednesday, Oct. 15th, from 8 to 11 P.M.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the Second Professional Examination in Anatomy and Physiology held on Sept. 25th, 26th, 29th, and 30th, for which 81 candidates presented themselves, of whom 51 were approved and 30 were rejected, the following candidates were successful:—

William Fletcher Barrett, Charing Cross Hospital; John Behesnilian, and Richard Vincent Bevan, Charing Cross Hospital and King's College; Antoun Bishara, St. Thomas's Hospital; Alberto Henriques Ferreira Bizarro, M.D. Lisbon, Lisbon University and University College; Edgar Scott Bowes, Guy's Hospital; Ingram Richard Rhodes Brogden, B.A. Cantab., Cambridge University and Guy's Hospital; Hari Chan, L.M.S. Punjab, Lahore Unversity; Raghunath Ganesh Dani, University College; Frank Philip Gilbert de Smidt, London Hospital; David McMurray Dickson, St. Thomas's Hospital; Geoffrey Barrow Dowling, Guy's Hospital; Nashed Fahmy, Cairo and King's College; Roy Fazan, Middlesex Hospital; Sourendra Mahon Ghosh, L.M.S. Calcutta, Calcutta University; Edward Austin Gibb, B.A. Cantab., St. Thomas's Hospital; Farid Yusif Hassaballa, University College; Wilhelm Otto Holst, Middlesex Hospital; John Robert John, University College, Cardiff; Llewellyn Price Johns, King's College; Dadabhai Nowroji Kalyanvala, L.M. & S. Bombay, Bombay University and University College; Theodore Louis Kan, King's College; Dhanjishaw Phirozshaw Karaka, L.M. & S. Bombay, Bombay University and London Hospital; Thomas William Le Mesurier, London Hospital; Noel Heathcote Seton Maelzer, Guy's Hospital; Francis Keene Marriott, London Hospital; Vaman Raghunath Mirajkar, L.M. & S. Bombay, Bombay University and St. Bartholomew's Hospital; Ernest Cecil de Mallet Morgan, Guy's Hospital; Frederick Maurice Mosely, B.A. Cantab., Cambridge University and London Hospital; Bidhan Prosad Mozoomdar, L.M. & S. Calcutta, Calcutta University; Sinnethamby Muttiah, London Hospital; Canapathy Pillai Nagamuttu, Ceylon Medical College and Middlesex Hospital; Wilfrid Guy Stuart Neely, L.D.S. Eng., Guy's Hospital; Baddelianage Don Hugo Philip, Ceylon Medical College and London Hospital; Robert Louis Portway, Guy's Hospital; Charles Young Roberts, St. Thomas's Hospital; Abdel Raoof Roushdy, Cairo and King's College; Percy Gunn Russell, Middlesex Hospital; Bishambhar Sahai, Calcutta University; James Ernest Scanlan, St. Mary's Hospital; Ronald James Scarr, Manchester University; John Milnes Smith, Middlesex Hospital; Godfrey Trehane Symons, King's College; John Aylmer Tippet, St. Thomas's Hospital; Martin Baird Moore Tweed, Guy's Hospital; Douglas James Valentine, London Hospital; Harry Cecil Craven Veitch, University College; Herbert Stewart Wacher and Leonard Pengelly Waghorn, Guy's Hospital; and Alban Wilson and Ismail Zaki, University College.

FOREIGN UNIVERSITY INTELLIGENCE.—*Stuttgart:* Dr. Karl Baisch, professor of obstetrics in the University of Munich, has been appointed Chief Physician to the new Gynæcological Department of the Municipal Hospital of St. Katherine.—*Vienna:* Dr. Jakob Erdheim has been recognised as *privat-docent* of Pathological Anatomy.

MANCHESTER ROYAL INFIRMARY OLD RESIDENTS' CLUB.—A meeting of this club will be held at the Midland Hotel, Manchester, on Saturday, Oct. 18th, at 6.30 P.M. The meeting will be followed, at 7 P.M., by a dinner, at which Mr. George H. Pinder will preside. Any old resident who has failed to receive a notice is requested to apply to the secretaries, Royal Infirmary, Manchester.

MIDDLESEX HOSPITAL MEDICAL SCHOOL.—The following is the result of the Entrance Scholarships examinations at this school:—University Scholarship, J. J. O. Beven (Cambridge); First Entrance Scholarship, S. C. Shaw; Second Entrance Scholarship, O. L. C. Sibley; Third Entrance Scholarship, G. F. W. Howorth; and Freer Lucas (Epsom) Scholarship, L. W. Hefferman.

DONATIONS AND BEQUESTS.—By will the late Mr. William Weir, of Kildonan, has left £10,000 each to the Glasgow Royal Infirmary and the Glasgow Western Infirmary, £5000 each to Glasgow Victoria Infirmary and the University of Glasgow for additional assistant to the professor of materia medica, £2000 each to the Kilmarnock Infirmary and the Ayr Infirmary, and £500 each to the Glasgow Eye Infirmary and the Glasgow Ophthalmic Institution.—By the death of Mr. Thomas Ryder, of Harrogate, a sum of £20,000, left by his wife to build and endow a hospital at Middleton, subject to the life interest in this sum of her husband and her mother, has now become available for building and endowing a hospital at Middleton, Lancs.—Dr. John Albert Nunneley has left a sum of nearly £45,000 before deduction of legacy duty to the Leeds General

Infirmary and the Royal Mineral Water Hospital, Bath. The first-named institution will receive two-thirds and the other one-third.

THE temporary address of the Wellcome Bureau of Scientific Research until further notice will be 54A, Wigmore-street, London, W.

THE University Scholarship at St. Thomas's Hospital has been awarded to H. H. Monk Gould, of Charterhouse and Clare College, Cambridge.

THE Order of the Red Eagle, Third Class, has been conferred upon Surgeon-General W. Schultzen, of the War Office, Berlin.

Dr. Bruegel, of Munich, has been granted the rank and title of Court Physician.

HARVEIAN SOCIETY OF LONDON.—This society will hold a clinical meeting at 8 P.M. on Thursday, Oct. 16th, at Paddington Green Children's Hospital, when Dr. Leonard G. Guthrie will take the chair. Cases will be shown by the hospital staff. Members wishing to show cases are requested to communicate with the honorary secretary, Mr. Duncan C. L. Fitzwilliams, 31, Grosvenor-street, Grosvenor-square, W.

CENTRAL LONDON THROAT AND EAR HOSPITAL.—The winter session of the Central London Throat and Ear Hospital, Gray's Inn-road, will commence on Friday, Oct. 17th, when Dr. Thomas James Walker will deliver the inaugural address, "Laryngoscopy 1860 to 1913: a Retrospect," at 3 P.M. The annual dinner of the staff with past and present students will take place the same evening at the Trocadero Restaurant, Dr. Dan McKenzie being in the chair.

LITERARY INTELLIGENCE.—We understand that a French translation by Professor Léon Guinet of the second edition of Dr. H. Charlton Bastian's work "The Origin of Life" has been published by H. Lamertin, of Brussels. The article by Dr. Bastian entitled "Spontaneous Generation: its Reality and what it Implies," which appeared in the June number of the *English Review*, has also been translated into French, and is published in the *Revue Scientifique* for Sept. 27th.

BRIGHTON THROAT AND EAR HOSPITAL, Church-street, Queen's-road.—Non-resident House Surgeon for six months. Salary at rate of £100 per annum.

BRISTOL GENERAL HOSPITAL.—First House Physician, Second House Physician, and Casualty House Surgeon, for six months. Salary £80 per annum, with board, residence, &c.

BRISTOL ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN.—House Physician. Salary £80 per annum, with board, rooms, and attendance.

BRISTOL ROYAL INFIRMARY.—Dental House Surgeon for six months. Salary at rate of £100 per annum, with board, apartments, and laundry.

BURY INFIRMARY.—Junior House Surgeon. Salary £100 per annum, with board, residence, and washing.

CARDIFF, KING EDWARD VII.'s HOSPITAL.—House Surgeon for six months. Salary at rate of £60 per annum, with board, residence, and laundry.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Pathologist Salary £40 per annum.

CHELTENHAM GENERAL HOSPITAL.—House Physician, unmarried. Salary £100 per annum, with board, lodging, and washing.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—Surgeon.

COLCHESTER, ESSEX COUNTY HOSPITAL.—House Surgeon. Salary £100 per annum, with board, washing, and residence.

DOWNPATRICK, DOWN DISTRICT LUNATIC ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £130 per annum, with apartments, board, washing, attendance, &c.

DUMFRIES AND GALLOWAY ROYAL INFIRMARY.—Assistant House Surgeon. Salary £65 per annum, with board and washing.

EASTERN DISPENSARY, Lemon-street, E.—Resident Medical Officer. Salary £120 per annum, with residence and attendance.

GENERAL POST OFFICE, HEADQUARTERS MEDICAL DEPARTMENT.—Assistant on Headquarters Medical Staff. Salary £200 per annum.

GLASGOW DISTRICT MENTAL HOSPITAL, Gartloch.—Junior Medical Officer. Salary £150 per annum, with board, lodging, and laundry.

GOVAN DISTRICT ASYLUM, Crookston, near Paisley.—Second Assistant Medical Officer, unmarried.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway-road, London, N.—Resident Medical Officer. Salary £120 per annum, with board, residence, and laundry.

GREAT YARMOUTH HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and washing.

HALIFAX ROYAL INFIRMARY.—Third House Surgeon, unmarried. Salary £80 per annum, with residence, board, and washing.

HAMLET OF MILE END OLD TOWN.—Junior Assistant Medical Officer. Salary £120 per annum, with board, lodging, and washing.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL.—Ophthalmic Surgeon to Out-patients. Also Medical Officer in Charge of X Ray Department. Salary 25 guineas per annum.

HASTINGS, EAST SUSSEX HOSPITAL.—Assistant House Surgeon. Salary at rate of £70 per annum, with residence, board, and washing.

HEREFORD COUNTY AND CITY ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £200 per annum and all found.

HOSPITAL FOR EPILEPSY AND PARALYSIS AND OTHER DISEASES OF THE NERVOUS SYSTEM, Maida Vale, W.—Resident Medical Officer for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—Assistant Casualty Medical Officer, unmarried, for six months. Salary £30, with board, residence, &c. Also Medical Registrar. Salary £200 per annum.

HULL ROYAL INFIRMARY.—House Physician, unmarried. Salary £100 per annum, with board and apartments. Also Casualty House Surgeon for six months. Salary at rate of £80 per annum, with board and lodging.

KENSINGTON DISPENSARY AND CHILDREN'S HOSPITAL.—Resident Medical Officer, unmarried. Salary £100 per annum, with board, apartments, laundry, &c.

KIMBERLEY, KIMBERLEY HOSPITAL, South Africa.—Bacteriologist and Pathologist. Salary £600 per annum and board.

KING EDWARD MEMORIAL HOSPITAL, Ealing, W.—Resident Medical Officer for six months. Salary at rate of £80 per annum, with board, residence, and laundry.

LEEDS GENERAL INFIRMARY.—House Surgeon for six months. No salary, but board, residence, and laundry provided. Also Resident Obstetric Officer for six months. Salary £50 per annum, with board, residence, and laundry. Also Resident Medical Officer for three or six months at Ida and Robert Arthington Hospitals. Salary £60 per annum, with board, residence, and laundry.

LEEDS PUBLIC DISPENSARY.—Junior Resident Medical Officer. Salary £100 per annum, with board, residence, and laundry.

LEICESTER BOROUGH MENTAL HOSPITAL, Humberstone.—Second Assistant Medical Officer and Pathologist, unmarried. Salary £240 per annum.

LEICESTER ROYAL INFIRMARY.—Surgical Dresser. Salary £10 10s. for six months, with board, lodging, and washing.

LEWES VICTORIA HOSPITAL.—Resident Medical Officer. Salary £120 per annum, with apartments, board, washing, attendance, &c.

LEYTON, WALTHAMSTOW, AND WANSTEAD CHILDREN'S AND GENERAL HOSPITAL.—Resident House Surgeon. Salary at rate of £100 per annum, with rooms, board, and washing.

LIVERPOOL, PARKHILL SANATORIUM.—Resident Medical Superintendent, unmarried. Salary at rate of £400 per annum, with board, residence, and washing.

LONDON COUNTY ASYLUM, Hanwell, W.—Junior Assistant Medical Officer, unmarried. Salary £170 per annum, with board, apartments, and washing.

LONDON FEVER HOSPITAL, Liverpool-road, Islington, N.—Resident Medical Officer. Salary £250 per annum, with board and residence.

LONDON LOCK HOSPITAL.—Assistant House Surgeon. Salary £80 per annum, with board, lodging, and washing. Also House Surgeon to Female Hospital, Harrow-road, W. Salary £100 per annum, with board, residence, and washing.

LONDON MISSIONARY SOCIETY, 16, New Bridge-street, E.C.—Female Medical Missionaries for Central China and South India.

MACCLESFIELD GENERAL INFIRMARY.—Senior House Surgeon and Junior House Surgeon. Salary £100 and £80 per annum respectively, with board and residence.

MANCHESTER, CITY OF.—Two Assistant Tuberculosis Officers. Salary £300 per annum.

MANCHESTER SCHOOLS FOR MOTHERS.—Medical Officer. Salary £250 per annum.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—House Physician and House Surgeon. Salary at rate of £80 per annum, with board and washing. Also Assistant House Physician and Assistant House Surgeon. Salary at rate of £40 per annum, with board and washing. All for six months. Also Pathologist and Registrar. Salary at rate of £120 per annum. Also Assistant Physician.

NATIONAL DENTAL HOSPITAL AND COLLEGE, Great Portland-street, W.—Honorary Radiologist.

NEWCASTLE-UPON-TYNE EDUCATION COMMITTEE.—Second Whole-time Assistant Medical Officer. Salary £250 per annum.

NEWCASTLE-UPON-TYNE, HOSPITAL FOR SICK CHILDREN.—Senior Medical Officer and Junior Medical Officer for six months. Salary £100 and £80 per annum respectively, with board, lodging, and laundry.

NEWCASTLE UPON-TYNE, ROYAL VICTORIA INFIRMARY.—Refraction Clerk. Salary £50 per annum.

NEWCASTLE-UPON-TYNE, UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.—Lecturer in Diseases of the Throat, Nose, and Ear, Diseases of the Skin, and Diseases of Children.

NORTHAMPTON COUNTY ASYLUM, Berry Wood, Northamptom.—Junior Assistant Medical Officer. Salary £200 per annum, with board, lodging, and washing.

NOTTINGHAM GENERAL HOSPITAL.—Assistant House Physician. Salary £100 per annum, with board, residence, and laundry.

OLDHAM ROYAL INFIRMARY.—Second House Surgeon and Third House Surgeon for six months. Salary at rate of £100 and £80 per annum respectively, with residence, board, and laundry.

ORKNEY, ROUSAY AND EGILSHAY PARISH.—Resident Medical Officer. Salary £71 per annum.

OXFORD COUNTY ASYLUM, Littlemore, near Oxford.—Assistant Medical Officer. Salary £150 per annum, with apartments, board, and washing.

OXFORD EYE HOSPITAL, Walton-street.—House Surgeon. Salary £100 per annum, with rooms, board, and laundry.

PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W.—House Physician and House Surgeon for six months. Salary at rate of £52 10s. per annum in each case, with board and residence.

PADDINGTON INFIRMARY.—Second Assistant to Infirmary and Medical Officer of Workhouse. Salary at rate of £100 per annum, with board, lodging, and washing.

PARK HOSPITAL FOR CHILDREN, Hither Green, London, S.E.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing.

PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—House Physician for six months. Salary £75 per annum, with board, residence, and washing.

POPLAR HOSPITAL FOR ACCIDENTS, Poplar, E.—Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board and residence.

Births, Marriages, and Deaths.

BIRTHS.

BOULTON.—At Rockcliffe, Mussoorie, India, to Major Harold Boulton, I.M.S., and Mrs. Boulton (*née* Maud Mary Garton), a daughter.

RIDOUT.—On Sept. 30th, at St. Elmo, Clarendon-road, Southsea, Hants, to the wife of C. A. Scott Ridout, M.S., F.R.C.S., a son.

MARRIAGES.

BENNETT—TAYLOR.—On Oct. 3rd, at St. Clement's Church, Ste. Madelaine, Trinidad, Richard Charles Bennett, M.B., C.M., to Rose Florence, elder daughter of Mr. and Mrs. G. W. Taylor, "Cliftonville," The Polygon, Southampton.

DEATHS.

FAIRBANK.—On Oct. 3rd, suddenly, at Felixstowe, Caversham, Oxon., Frederick Roylston Fairbank, M.D., F.S.A., aged 72 years.

THORP.—On Oct. 3rd, at Henley-road, Ipswich, from pneumonia, Henry John Thorp, M.D., aged 81 years.

WALKER.—On Sept. 30th, as the result of an accident, Henry George Walker, M.D.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

HEALTH AND HOSPITALS IN GAMBIA.

A REPORT by Mr. W. T. Campbell, Colonial Secretary of Gambia, on the Blue-book of the colony for 1912 has been issued as a Parliamentary paper. It gives the population of the colony as 7700 and of the protectorate as 149,468. The number of Europeans, including females, residing in the colony and protectorate during the year was 198. Of these, 17 were invalided and 3 died. The general health was satisfactory and the year was fortunately free from yellow fever, of which there had been an outbreak in 1911. There were 1914 vaccinations performed in Bathurst and 867 in the protectorate. Arrangements have been made for a medical officer to travel through the protectorate and carry out vaccinations, and it is hoped that this will give more satisfactory results. The campaign against mosquitoes has been vigorously carried out, and has resulted in greatly diminishing their number. After the last case of yellow fever in November, 1911, the fumigation of all Government quarters, cellars, and many private buildings was undertaken. The stegomyia species of mosquito has almost disappeared. Among the mosquitoes found in different parts of Bathurst at the end of the year only two were stegomyia; the remainder were mainly culex. The clearing of about 40 acres of mangrove on the western side of the town has greatly diminished the number of mosquitoes in that quarter. The climate of the Gambia is pleasant during the dry season, which lasts from November to May. For the remaining months the conditions are similar to those experienced elsewhere on the West Coast of Africa. The damp and enervating weather is very oppressive and more generally felt, after the several rainless months, than is the case elsewhere. The highest shade temperature recorded in Bathurst in 1912 was 104° F. and the lowest 58°. The rainfall was 33·99 inches.

The hospital at Bathurst has accommodation for 4 first-class, 11 second-class, and 10 third-class male patients and 15 female patients, including two cots for children. There are also four rooms for isolation cases. The wards for males and females are in separate buildings. A new hospital at MacCarthy Island was opened in 1911, and is in charge of a European medical officer. It contains a ward for Europeans and three wards for native patients. There is also a contagious diseases hospital, situated about two miles from Bathurst. Four mild cases of small-pox, all of which recovered, were treated in this building during the year. The total number of patients treated in the Bathurst Hospital was 529, of whom 33 died, and in the out-patients' department 7895. At the MacCarthy Island Hospital 66 in-patients and 1356 out-patients were treated.

A DELETION FROM THE MEDICAL DIRECTORY.

To the Editor of THE LANCET.

SIR,—I asked the authors of this useful book if they intended to indicate a practitioner was "on the panel," and they inform me they do not mean to show the distinction. The Directory will be wort less to me, and I have told them to delete my name. I do not intend that the public shall wonder whether I am a "panel doctor." This matter is of immense importance to the profession and the public generally.

I am, Sir, yours faithfully,

JAMES BRASSEY BRIERLEY, M.D. Edin.

Manchester, Oct. 6th, 1913.

TUBERCULOSIS AND THE CINEMATOGRAPH.

To the Editor of THE LANCET.

SIR,—Can any of your readers tell me where cinematograph films suitable to illustrate a popular lecture on consumption can be obtained?

I am, Sir, yours faithfully,

Earl Shilton, Hinckley, Oct. 6th, 1913. PHILIP GELL GARRETT.

"WORM NODULES" IN AUSTRALIAN BEEF.

THE Australian Institute of Tropical Medicine, established in 1908 and enlarged in 1912, has already done good work. The annual report for 1911, now before us, is written by the director, Dr. Anton Breinl, in collaboration with his two colleagues, Mr. Frank H. Taylor, F.E.S., and Dr. T. Harvey Johnston, D.Sc. The institute, situated at Townsville in North Queensland, now receives an annual subsidy of £4000 from the Federal Government of Australia, and judging from the report now before us has already more than justified its existence. One of the chief investigations carried out was that directed towards the solution of the problems connected with the occurrence of "worm nodules" (onchocerciasis) caused by Onchocera gibsoni in Australian beef, an important subject to which we directed the attention of our readers in THE LANCET of Feb. 4th, 1911. Although the researches undertaken by the experts of the Australian Institute have not succeeded as yet in demonstrating the complete life-history of the parasite, it may nevertheless be said that these investigations have cleared up

a number of doubtful points; they have, for instance, definitely excluded mosquitoes, stomoxys calcitrans, and leeches as being intermediary hosts. Unfortunately, the wet season of 1911 was light and therefore unfavourable to the inquiry, experience having shown that the best opportunities for such a research are furnished by a heavy wet season in which a rich insect fauna is present.

THE INDIAN CIVIL SURGEON OF THE PAST.

A DESCRIPTION in the *Indian Planter's Gazette* of the civil surgeon of the dim past shows the progress made in India in the matter of medical attendance:—

> You would hardly guess from his appearance and ways that he was a surgeon and a medical man. He certainly does not smell of lavender or peppermint, or display fine or curious linen, or tread softly like a cat. Contrariwise he smells of tobacco, and wears flannel underclothing. His step is heavy. He is a gross, big, cow-buffalo sort of man, with a tangled growth of beard. His ranting voice and loud familiar manner amount to an outrage. He laughs like a camel, with deep bubbling noises. Thick corduroy breeches and gaiters swaddle his shapeless legs, and he rides a coarse-bred Waler mare. I pray the gods that he may never be required to operate upon my eyes, or intestines, or any other delicate organ.

THE IDEAL BREAKFAST.

To the Editor of THE LANCET.

SIR,—*A propos* of your recent annotation on "meals" may I suggest that—

"*Un œuf* is as good as a feast"

sums up the true philosophy of breakfast diets.

I am, Sir, yours faithfully,

Oct. 8th, 1913. W. B. A.

MEDICAL AFFAIRS IN FIJI.

THE report on the Blue-book of this colony for the year 1912 estimates the total population at 149,179, made up of 4131 Europeans, 2512 half-castes, 48,614 Indians, 2769 Polynesians, 1965 Rotumans, 87,833 Fijians, 397 Chinese, and 958 others. The total rainfall recorded at Suva during the year was 115·406 inches. The highest temperature in the shade was 92·0° F. on March 18th, and the lowest 60·0° on August 25th. The Colonial Hospital at Suva, the principal medical institution, is under the charge of a resident medical officer, assisted by a junior medical officer, a matron, two staff nurses, one graduate nurse, and six pupil nurses, the whole being supervised by the chief medical officer. Admissions during 1912 numbered 1728, of whom 211 were Europeans. There is a branch hospital at Levuka under the charge of the district medical officer, assisted by a matron. This institution provides for the treatment of Europeans as well as natives. There are eight provincial hospitals for the treatment of native Fijians. These are supervised by Government medical officers. The number of admissions to these provincial hospitals during 1912 was 3917. There is a leper asylum on the island of Makogai, under the charge of a medical superintendent, assisted by two European nursing sisters and two native medical practitioners. On Dec. 31st, 1912, there were 154 lepers in the asylum. The work of collection and transportation of lepers formerly residing in all parts of the colony is now nearing completion.

M.D. (*Accrington*).—Yes.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY.

SPECIAL MEETING OF FELLOWS: at 5.30 P.M.

Demonstration by Dr. Hideyo Noguchi of the Rockefeller Institute.

(1) Pure Cultures of Various Spirochætæ (Treponema pallidum, T. pertenue, T. microdentium, T. macrodentium, T. mucosum, T. calligyrum, T. refringens).
(2) Transmission of Syphilis to Animals by means of Pure Cultures of Treponema pallidum.
(3) Demonstration of Treponema pallidum in the Brain of General Paralytics.
(4) Transmission of Treponema pallidum from the Brain of General Paralytics to the Rabbit.
(5) Production of Symptoms and Lesions resembling General Paralysis in the Rabbit by means of an Intracerebral or Subdural Inoculation with Treponema pallidum.
(6) Cultural Studies of the Virus of Rabies.

Illustrated by Lantern Slides.

TUESDAY.

SECTION OF SURGERY (Hon. Secretaries—J. Murray, Raymond Johnson): at 5.30 P.M.

Mr. Charles A. Pannett: The Selection of the Incision in Cœliotomy.

Mr. Frank Kidd: Pyeloradiography.

Short Historical Survey and Description of the Method. Applications in Practice. Examples will be shown to Illustrate the Diagnosis of Congenital Abnormalities of the Kidney and Ureter, Dilatation of the Kidney, Stone in the Kidney, Abdominal and Renal Neoplasms, &c. Skiagrams exhibited by Mr. Gilbert Scott. Experimental Studies to show the Effect on the Kidney of the Injection of Colloid Silver into the Renal Pelvis. Pathological Reports by Dr. H. M. Turnbull. Experimental Work by Mr. E. C. Lindsay.

THURSDAY.

SECTION OF DERMATOLOGY (Hon. Secretaries—J. M. H. MacLeod, S. E. Dore): at 5 P.M.

Dr. Haldin Davis: Demonstration of Coloured Lantern Slides of Skin Diseases made by the Paget Prize Process.
Dr. Knowsley Sibley: Case of Nævus Linearis Bilateralis.
Dr. J. M. H. MacLeod: Case for Diagnosis.

And other Cases.

FRIDAY.

SECTION OF OTOLOGY (Hon. Secretaries—G. J. Jenkins, G. N. Biggs): at 5 P.M.

Mr. W. M. Mollison: Case of Fracture of the Skull with Injury to the Cranial Nerves.
Mr. Sydney Scott: Case of Purulent Lepto-meningitis with Rapid Recovery after Trans-labyrinthine Operation.

And other Cases.

SECTION OF ELECTRO-THERAPEUTICS (Hon. Secretaries—Cecil R. C. Lyster, S. Gilbert Scott): at 8.30 P.M.

Clinical Evening:

Members are invited to bring Specimens, Cases, or Plates.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8 P.M., General Meeting. 8.30 P.M., The President (Sir David Ferrier, M.D.):—Introductory Address. Paper:—Dr. F. Buzzard: Varieties of Facial Spasm and their Treatment.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

FRIDAY.—5 P.M., Prof. Keith: Specimens illustrating the Lesions of Achondroplasia, Osteogenesis Imperfecta, and Allied Conditions. (Museum Demonstration.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. G. N. Meachen: Clinique (Skin). 5.15 P.M., Lecture:—Dr. F. E. Batten: The Use of Celluloid Splints in the Treatment of Acute Cases of Poliomyelitis and Other Nervous Disorders.

TUESDAY.—4 P.M., Dr. H. Campbell: Clinique (Medical). 5.15 P.M., Lecture:—Dr. C. Lockyer: Prolapse.

WEDNESDAY.—4 P.M., Mr. E. C. Hughes: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. S. E. Dore: Alopecia and its Treatment.

THURSDAY.—4 P.M., Mr. A. H. Tubby: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. E. A. Cockayne: Jaundice.

FRIDAY.—4 P.M., Mr. R. R. James: Clinique (Eye). 5.15 P.M., Lecture:—Dr. H. C. Miller: Clinical Psychology—3. The Methods and Technique of Psycho-Therapy.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. Owen: Aneurysm.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin. 5 P.M., Lecture:—Dr. Owen: Aneurysm.

WEDNESDAY.—Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 11 A.M., Mr. Souttar: Demonstration of Minor Operations. 12 noon, Mr. Souttar: Abdominal Diagnosis. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Dr. Owen: Aneurysm.

THURSDAY.—10.30 A.M., Dr. Simson: Gynæcological Demonstration. 12.15 P.M., Lecture:—Dr. G. Stewart: Neurological Cases. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. T. Gray: Disturbances of the Motor Functions of the Intestines.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 10.30 A.M., Lecture:—Dr. Owen: Practical Medicine. 12.15 P.M., Lecture:—Dr. Bernstein: Clinical Pathology. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin. 5 P.M., Lecture:—Mr. T. Gray: Disturbances of the Motor Functions of the Intestines.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 12 noon, Mr. Souttar: Surgical Anatomy of the Abdomen. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—Out-patient Demonstrations:—10 A.M. Dr. Singer: Medical. Mr. H. Curtis: Surgical. 12 noon, Mr. G. N. Biggs: Throat, Nose, and Ear.—2.15 P.M., Mr. W. Turner: Surgery. 3 P.M., Mr. W. Turner: Operations. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.15 P.M., Mr. R. Lake: Ear and Throat 3.15 P.M., Special Lecture:—Sir Dyce Duckworth: Endocarditis and its Sequels.

TUESDAY.—Out-patient Demonstrations:—10 A.M., Dr. G. Holmes: Medical. Mr. Cole: Surgical. 12 noon, Dr. H. MacCormac: Skin.—2 P.M., Mr. L. McGavin: Operations. 2.15 P.M., Mr. R. Carling: Surgery. 3.15 P.M., Dr. G. Rankin: Medicine. 4.30 P.M., Special Lecture:—Dr. C. Zundel: Heart Block.

WEDNESDAY.—Out-patient Demonstrations: 10 A.M., Dr. F. Langmead: Medical. Mr. C. Rowntree: Surgical. 11 A.M., Mr. R. E. Bickerton: Eye.—2 P.M., Mr. L. V. Cargill or Mr. Choyce: Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.15 P.M., Mr. Cargill: Eye Clinique. 4.30 P.M., Mr. C. C. Choyce: Surgery.

THURSDAY.—Out-patient Demonstrations:—10 A.M., Dr. Singer: Medical. Mr. H. Curtis: Surgical. 12 noon, Mr. G. N. Biggs: Throat, Nose, and Ear.—2 P.M., Mr. R. Carling or Mr. W. Turner: Operations. Dr. A. Davies: Pathological Demonstration. 3.15 P.M., Dr. R. Wells: Medicine. 4.30 P.M., Special Lecture:—Mr. C. Rowntree: Common Affections of the Anus.

FRIDAY.—Out-patient Demonstrations;—10 A.M., Dr. G. Holmes: Medical. Mr. Cole: Surgical. 12 noon, Dr. H. MacCormac: Skin.—2 P.M., Mr. L. McGavin: Operations. 2.15 P.M., Sir John Rose Bradford; Medicine 3.15 P.M., Mr. L. McGavin: Surgery.

SATURDAY.—Out-patient Demonstrations: 10 A.M., Dr. F. Langmead: Medical. Mr. C. Rowntree: Surgical. 11 A.M., Mr. R. E. Bickerton: Eye.—10 A.M., Col. Barry: Radiography.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY.—4.30 P.M., Lecture:—Dr. Inman: The Behaviour of the Blood in Response to Tuberculous Infection.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Dr. J. Collier: Vascular Lesions of the Brain.

FRIDAY.—3.30 P.M., Clinical Lecture:—Dr. J. Collier: Inflammatory Lesions of the Brain.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

MANCHESTER HOSPITALS POST-GRADUATE CLINIC.

TUESDAY.—SALFORD ROYAL HOSPITAL—4.30 P.M., Dr. F. E. Tylecote: Some Recent Cases of Nephritis.

WEDNESDAY.—ROYAL INFIRMARY—4.30 P.M., Exhibition of Medical and Surgical Cases in conjunction with the Medical Society.

THURSDAY.—ANCOATS HOSPITAL—4.30 P.M., Mr. W. R. Douglas: Surgical Aspect of Gastric Carcinoma.

FRIDAY.—ROYAL EYE HOSPITAL—4.30 P.M., Dr. H. H. McNabb: Detection of Opacities in the Media.

ROTUNDA HOSPITAL POST-GRADUATE COURSES, Dublin.

MONDAY.—10 A.M., Obstetrical Lecture: The Diagnosis of Pregnancy. 11 A.M., Examination of Patients and Minor Operations.

TUESDAY.—10 A.M., Major Operations.

WEDNESDAY.—10 A.M., Obstetrical Lecture: The Phenomena of Labour. 11 A.M., Examination of Patients and Minor Operations.

THURSDAY.—10 A.M., Major Operations.

FRIDAY.—10 A.M., Gynæcological Lecture: Tumours of the Ovary. 11 A.M., Examination of Patients and Minor Operations.

For further particulars of the above Lectures, &c., see Advertisement Pages.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced:—

April 26th–Nov. 5th (Ghent).—International Exhibition.
May 31st to October (London, Earl's Court).—Imperial Services Exhibition.
May–October (Leipzig).—First International Building Exhibition.
June 24th–Oct. 31st (London, 54a, Wigmore-street).—Historical Medical Museum. (Organised by Mr. Henry S. Wellcome.)
June–October (London, Crystal Palace).—Anglo-German Exhibition.
Oct. 1st–Nov. 1st (London, Shepherd's Bush).—National Gas Exhibition.
" 9th–25th (London, Olympia).—Ideal Home Exhibition.
" 22nd–25th (Berlin).—Eleventh International Anti-Tuberculosis Conference.
" 28th–Nov. 1st (London, Royal Horticultural Hall).—Twenty-fourth Universal Cookery and Food Exhibition.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial Staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Communications, Letters, &c., have been received from—

A.—Ardath Tobacco Co., Lond.; Dr. J. P. Aiken, Camlough; Dr. D. E. Anderson, Paris; Avondale, Southbourne-on Sea; Mr. J. W. Arrowsmith, Bristol; Anglo-American Pharmaceutical Co., Croydon; Dr. R. W. Allen, Lond.; Dr. M. El Aroosy, Cairo; Dr. D. E. Anderson, Highgate; Messrs. Claudius Ash, Sons, and Co., Lond.

B.—Messrs. C. Birchall, Liverpool; Mr. C. S. Buck, St. Albans; Mr. W. T. Beswick, Cambridge; Messrs. Bruce, Green, and Co., Lond.; Dr. Andrew Balfour, Lond.; Mr. W. Bentley, Lancaster; Messrs. A. J. Burckhardt and Co., Lond.; Surgeon J. L. Barford, R.N., Simonstown; Birmingham Corporation, Treasurer to the; Dr. J. Mitchell Bruce, Lond.; Mrs. Cloudesley Brereton, Lond.; Mr. R. C. Brown, St. Kilda; Dr. J. B. Brierley, Manchester; Dr. A. Besredka, Paris; Bath Royal United Hospital, Secretary of; Mr. Albert Benthall, Lond.; Bury Infirmary, Secretary of.

C.—Messrs. J. and A. Churchill, Lond.; Dr. Cunliffe, Manchester; Mr. W. A. Crosbee, Malvern; Clayton Hospital, Wakefield, Hon. Secretary of; Messrs. Curling, Wyman, and Co., Lond.; Messrs. Clarke, Son, and Platt, Lond.; Dr. J. Cates, St. Helens; Messrs. Corbyn, Stacey, and Co., Lond.; Dr. Alice Corthorn, Lond.; "Colonel" Theodore Kitching, Lond.; Camberwell Guardians, Lond., Clerk to the; Mr. F. W. Clarke, Chorlton-cum-Hardy; Messrs. Carnrick and Co., Lond.; Mr. H. A. Collins, Croydon.

D.—Messrs. W. Dawson and Sons, Lond.; *Daily Mail*, Lond., Directors of; Dr. Patrick W. Diack, Lond.; Dr. Downer, Matlock; D. J. M.

E.—Dr. A. M. Elliot, Lond.; Messrs. Elliott, Son, and Boyton, Lond.

F.—Ford Motor Co., Manchester; Forward Publicity Co., Birmingham; Mr. H. Fromm, Pinner; Mr. George Foy, Dublin; Messrs. Fairchild Bros. and Foster, Lond.; Dr. C. B. Fox, Ilfracombe; Mr. Duncan C. L. Fitzwilliams, Lond.; Dr. Paul Fildes, Lond.; Messrs. Ferris and Co., Bristol; Dr. Fielden, Wengen.

G.—Gartloch Hospital, Gartcosh, Medical Superintendent of; Great Yarmouth Hospital, Hon. Secretary of; Governor of Bengal in Council, Calcutta; Dr. Eric Pearce Gould, Lond.; Dr. A. C. Gemmell, Brighton; General Electric Co., Lond.; Dr. Philip Gell Garrett, Earl Shilton; Guild of St. Luke, Sutton, Hon. Secretary of; Gloucestershire Royal Infirmary, Gloucester, Secretary of; Mr. J. Green, Lond.

H.—Mr. C. J. Hersey, Lond.; Dr. B. Hudson, Davos-Platz; Messrs. G. Head and Co., Lond.; Sir J. P. Hewett, Lond.; H., Acton; Mr. F. A. Hocking, Lond.; Dr. R. J. Hillier, Sheffield; Dr. W. P. Herringham, Lond.; Dr. J. Hay, Liverpool; Major L. W. Harrison, R.A.M.C., Lond.; Dr. C. F. Harford, Leyton; Mr. N. Bishop Harman, Lond.; Dr. D. Berry Hart, Edinburgh; Messrs. Harrison and Sons, Lond.; Holloway Sanatorium, Virginia Water, Medical Superintendent of; H. L.

J.—Miss E. M. Johnstone, Virginia Water; Messrs. J. F. Jones and Co., Paris.

K.—Messrs. H. S. King and Co., Lond.; King Edward Memorial Hospital, Lond., Secretary of; Messrs. Kutnow and Co., Lond.; Prof. A. Keith, Lond.

L.—London Temperance Male and Female Nurses' Co-operation, Lond., Secretary of; Messrs. Lepper, Lond.; London Press Exchange, Manager of; Messrs. Longmans, Green, and Co., Lond.; Mr. H. K. Lewis, Lond.; Leeds General Infirmary, Secretary of; Mr. A. Le Forestier, Lond.; Local Government Board, Lond., Medical Officer to; Leeds Public Dispensary, Secretary of; Dr. R. A. Lyster, Winchester; Leicester Royal Infirmary, Secretary of.

M.—Mr. R. Mosse, Berlin; Mr. R. Mosse, Cologne; Miss E. C. Macirone, Newcastle-on-Tyne; Mr. Cortlandt Macmahon, Lond.; Miss E. F. MacKinnon, Nairn; Mr. R. Matthews, Sheerness; Dr. P. W. MacDonald, Dorchester; Maltine Manufacturing Co., Lond.; Dr. Alexander Morison, Lond.; Dr. A. Macdonald, Lond.; Messrs. C. and E. Morton, Lond.; Dr. A. W. Meyer, Quincey; Mr. E. W. Marshall, Manchester; Messrs. Mather and Crowther, Lond.; Mr. E. Merck, Lond.; Mr. J. Murray, Lond.; Medical Agency, Lond., Secretary of; Messrs. J. Murdoch and Co., Lond.; Manchester Corporation, Clerk to the; Dr. M.; Macclesfield General Infirmary, Secretary of.

N.—Mr. H. Needes, Lond.; Northampton County Asylum, Secretary of; Newcastle-upon-Tyne Education Committee, Secretary of; National Dental Hospital, and College, Lond., Dean of; *Nursing Times*, Lond., Editor of; North Ormesby Hospital, Middlesbrough, Secretary of; Newcastle-upon-Tyne Hospital for Sick Children, Secretary of.

O.—Mr. Edmund Owen, Lond.; Sir William Osler, Bart., Oxford; Mr. W. D. O'Kelly, Dublin; Oldham Royal Infirmary, Secretary of; Oxford Eye Hospital, Secretary of.

P.—Mr. P. Paterson, Glasgow; Mr. R. H. Paramore, Bembridge; Mr. J. E. Purvis, Cambridge; Messrs. C. Pool and Co., Lond.; Dr. B.T. Parsons-Smith, Croydon; Mr. F. Tennant Pain, Lond.; Mr. H. W. Perkins, Lond.; Messrs. Parke, Davis, and Co., Lond.

R.—Mr. D. Ram, Almora; Royal Eye Hospital, Lond., Secretary of; Dr. J. A. Rivière, Paris; Rochdale Infirmary, Secretary of; Mr. Harry Rundle, Southsea; Royal Victoria Infirmary, Newcastle-on-Tyne, Secretary of; Royal South Hants and Southampton Hospital, Secretary of; Rousay Parish Council, Clerk to the; Royal Naval Medical Service, Lond., Director-General of; Royal College of Surgeons of England, Lond., Secretary of; Royal Portsmouth Hospital, Secretary of; Royal Halifax Infirmary, Secretary of; Messrs. Rhys Roberts and Co., Lond.

S.—Messrs. Swain, Hunnybun, and Taylor, Lond.; Messrs. Spottiswoode, Dixon, and Hunting, Lond.; Mr. J. Saul, Southport; Dr. Fred J. Smith, Lond.; Colonel Bruce Skinner, R.A.M.C., Lond.; Dr. Agnes Savill, Lond.; Dr. J. Edward Squire, Lond.; Dr. Josef Schnierer, Vienna; Sheffield Union, Clerk to the; St. Marylebone General Dispensary, Lond., Secretary of; Dr. J. Sinclair, Lond.; Messrs. W. B. Saunders Co., Lond.

T.—Dr. W. Bramley Taylor, Lond.; Mr. J. W. Thomson, Wakefield; Dr. John Tatham, Old Oxtead; Dr. William J. Tulloch, Newcastle-on-Tyne.

U.—University of Glasgow, Registrar of.

W.—West Herts Hospital, Hemel Hempstead, Secretary of; Mrs. Wallace, Lond.; Waterbury Chemical Co., Des Moines; West Riding County Council, Wakefield, Clerk to the; Dr. G. F. Whyte Dundee; Mr. C. A. Wallace, Aberdeen; Dr. C. Wall, Lond.; Dr. A. S. Worton, Lond.; Captain F. Wilson, I.M.S., Lond.; Messrs. J. Williams and Son, Bradford; Western Morning News Co., Barnstaple, Manager of; White Moss Coal Co., Skelmersdale.

Letters, each with enclosure, are also acknowledged from—

A.—Dr. J. M. Atkinson, Lond.; Aberystwyth Infirmary, Secretary of; Apollinaris Co., Lond.; Messrs. Allen and Hanburys, Lond.; A. A. M.; A. P.

B.—Dr. R. P. Beatty, Swindon; Dr. G. S. Blandy, St. Albans; Mr. C. S. Bowker, Pontnewydd; Bolton Infirmary, Secretary of; Dr. Buckmaster, Lond.; Mr. E. Bougault, Paris; Messrs. Brackstone and Co., Colwyn Bay; Dr. S. A. Bonnerjee, Lond.; Messrs. T. B. Browne, Lond.; Bank of Bombay, Bombay, Manager of; Dr. J. C. Bowie, Cardiff; Dr. W. Bain, Harrogate; Benger's Food, Manchester, Secretary of; Mr. F. Balkwill, Newport, Monmouthshire; Dr. R. H. Bellwood, Nottingham.

C.—Dr. Curtis, Lond.; Messrs. Cutting and Underwood, Lond.; Messrs. T. Christy and Co., Lond.; Messrs. Crossley and Co., Lond.; Mr. G. C. Cameron, Saskatoon; Mr. R. H. Carpenter, Bristol; Dr. F. G. Caley, Lond.; Mrs. Cook, Southall; Mr. W. E. Coleman, Wednesbury.

D.—Mr. M. E. Dovaston, Lond.; Dr. M. Dockrell, Lond.; Dr. J. W. Duffus, Port Elizabeth; Professor Delépine, Manchester; Dr. W. T. Dougal, Pittenweem; Dorland Agency, Lond.

E.—Mr. A. R. Elliott, New York; Dr. C. Enfield, Jefferson, U.S.A.

F.—Messrs. Flood and Sons, Lond.; Mr. W. V. Field, Kimberley; Fifth Avenue Bank, New York, Manager of.

G.—Dr. T. H. Gibson, Kirkby Stephen; Dr. S. Gill, Formby; Mr. H. S. Gettings, Wakefield; Mr. H. W. Goodman, Lond.; Mr. M. Greer, Corris.

H.—Mr. A. W. Hayward, Bournemouth; Messrs. C. J. Hewlett and Son, Lond.; Harrogate Hydropathic Co., Manager of; Mr. H. G. Hirons, Lewes; Haydock Lodge Retreat, Newton-le-Willows, Secretary of; Messrs. Hastings Bros., Lond.

J.—Mr. W. H. Jalland, York; Mr. W. Owen Jones, Bowdon; Mr. T. Jubb, Lytham.

K.—Mr. D. C. Kelly, Carnarvon; Mr. C. Kerr, Truro.

L.—Mr. C. B. Lockwood, Lond.; Messrs. Leach and Son, Wisbech; Leicester Mental Hospital, Secretary of; Mr. Long, Dover; Lyon, Lond.

M.—Dr. H. C. Martin, Caerleon; Messrs. J. Mundy, Gilbert, and Co., Birmingham; Mr. A. L. Moreton, Lond.; Mr. J. E. May, Lond.; Dr. M. Martin, Glasgow; Dr. F. W. Martin, Pengam; Dr. A. W. Mackay, Inverness; Dr. F. Meyer, Melbourne; Mundesley Sanatorium, Secretary of; Mr. G. B. Messenger, Sheffield; Mr. B. Miller, Lond.

N.—Mr. A. W. Nuthall, Birmingham; Northampton County Borough Education Committee, Secretary of; North Lonsdale Hospital, Barrow-in-Furness, Treasurer of; Nurse, Builth Wells.

P.—Miss C. Pring, Bristol; Messrs. G. Pulman and Sons, Lond.; Mr. E. Pearson, Ulverston; Pearson's Antiseptic Co., Lond., Secretary of.

Q.—Queen's University of Belfast, Bursar of.

R.—Mr. H. M. Riley, Leicester; Messrs. Roden and Wilkinson, Droitwich; Mr. H. C. Ross, Lond.; Mr. J. Rampton, Ascot; The J. D. Riedel Co., Lond.; Reuter's Telegram Co., Lond.; Mr. W. Ramsay, Melbourne; Royal Buckinghamshire Hospital, Aylesbury, Secretary of; Messrs. Reitmeyer and Co., Lond.; Rev. B. Rust, Lond.; Dr. S. Rideal, Lond.

S.—Mr. G. C. Stamper, Skegby; Messrs. G. Street and Co., Lond.; Messrs. Spiers and Pond, Lond.; *Shrewsbury Chronicle*, Manager of; Mr. L. Scudamore, Abertysswg; Messrs. G. and A. Smith, Lond.; South Shields Corporation, Accountant to the; Dr. G. I. T. Stewart, Ipswich; Messrs. Snaith and Sons, Darlington.

T.—Dr. C. C. Twort, Lond.; Messrs. Trever and England, Hull; Mr. T. W. Thomas, Caerphilly.

V.—Dr. J. Valentine, Maybole; Mr. O. Vevers, Norton.

W.—Messrs. Winter, Birmingham; West Ham and Eastern General Hospital, Lond., Secretary of; Messrs. W. Wood and Co., New York; W. E. G.; Warrington Infirmary, Secretary of; Dr. C. Woodhouse, Esher; Rev. G. H. Williams, Remenham; Dr. A. Watson, Stone.

Y.—Dr. Meredith Young, Chester.

Z.—Messrs. A. and M. Zimmermann, Lond.

A Lecture
ON
SOME APPLICATIONS OF ANTENATAL EUGENICS IN HEREDITY.

Delivered as one of the Post-Graduate Lectures at Edinburgh on Sept. 17th, 1913,

BY D. BERRY HART, M.D. EDIN., F.R.C.P. EDIN.,

LECTURER ON MIDWIFERY AND DISEASES OF WOMEN, SURGEONS' HALL, EDINBURGH; FORMERLY PHYSICIAN, ROYAL MATERNITY HOSPITAL; FORMERLY GYNÆCOLOGICAL PHYSICIAN, ROYAL INFIRMARY, EDINBURGH.

GENTLEMEN,—By Eugenics, a term introduced by Galton in 1883, we understand strictly the science "pertaining or adapted to the production of fine offspring, especially in the human race."[1] By National Eugenics Pearson means the science which has as its aim "the study of agencies under social control that may improve or impair the racial qualities of future generations either physically or mentally"; it has "the double meaning of goodness of nature and goodness of birth."[2] From its derivation, however, eugenics is a science antenatal in its scope, and it is this aspect I wish to discuss to-day—viz., How are man's qualities, in a broad sense, determined and transmitted so far as the zygote (or fertilised ovum) is concerned, and how can we affect this? National pos natal eugenics would then comprise all the rational means of preserving and conserving the health, bodily and mental, of human individuals after birth, and might be shortly termed "national hygiene."

The importance of our being alive to the value of antenatal eugenics cannot be over-estimated, and in support of this statement I may quote one statistical fact. According to the report of a Royal Commission in 1908 there were in England and Wales "149,628 mentally defective persons, in addition to certified lunatics, and ..... nearly half of them were in an unprovided condition and a standing menace to public safety."[3] If we take into account the mental anxiety and responsibility such unfortunates cause to their parents and guardians, their cost to the State, their greater fertility, so far as higher grade defectives are concerned, in comparison with normal individuals, as well as the high proportion of criminals among them, we must see in their unrestricted presence among our population a real and serious menace to the prosperity of the nation.

HEREDITY AND VARIATION.

The basis of eugenics is the well-known fact of heredity—viz., that the progeny of a race have, with some exceptions, the qualities making up their mental, bodily, and propagative powers from their parents and ancestors. Heredity, in fact, implies transmission. This, however, is a too limited conception. Qualities, normal and abnormal, may be found in progeny, which were not in their parents nor in their ancestors. Thus genital defects rendering an individual sterile turn up among us in by no means small numbers. They are not transmitted by their possessors, yet occur unexpectedly, and are not inherited as one might expect from a superficial interpretation of the term heredity. The same happens in some insects. The bulk of the inhabitants of a beehive consists of sterile females, the workers. Their mother is the queen bee and their father the drone, but they themselves have no offspring.[4] We must add therefore to our conception of transmission by heredity those of distribution and loss, both leading to variation.

Variation in heredity is a constant phenomenon. Individuals of a family are only approximately alike, vary from their father and mother and from one another. Every intelligent mother will tell you that her children are different and vary from her and her husband, often strikingly so, and may sometimes plaintively say, "I wonder where this child got *that*." We have, however, more exact evidence on this point of variation from finger-prints. These are an infallible means of settling identity in criminals, for instance. No instance of identity of finger-prints in separate individuals is known, except in cases of identical twins, where they are similar in the main.

How, then, are the transmission and distribution leading to normal variations brought about? How may abnormal conditions arise, defective and abnormal, and how are these transmitted? We must begin with an elementary consideration—viz., that each human male and female must be regarded as made up of "soma," or body, and heredity cells (ordinary ovum and spermatozoon) placed in the sexual gland, ovary in the female and testis in the male. The framework of the sexual gland is somatic. The "soma" is the actual body of the adult and exists only for the lifetime of the individual. Its qualities are the result of a certain distribution in the fertilised egg or zygote—that is, between the part of the latter giving rise to the soma and the other portion from which the heredity cells arise. The more exact mechanism of this will be discussed presently. The adult does not transmit certain of his "somatic" qualities by his "soma" but by his heredity cells. The transmissible qualities in the latter vary from those expressed in the soma, and thus one cannot say from a study of the latter that the progeny will have the same qualities or even many of them; they may have others not present at all in the parental or even in the ancestral soma. The destiny of the progeny lies, therefore, in the "heredity cells" as already defined, and it is to a right knowledge of the origin of these, of their metamorphoses in the sex gland, and of what happens to them at fertilisation, that we must look for light on the obscurity of our knowledge on heredity. How, then, do the heredity cells arise?

THE ORIGIN OF THE HEREDITY CELLS.

This distinction of "soma" and heredity cells is of supreme importance in heredity. It is customary to treat the question of transmission as going on from "soma" to "soma" in plants and animals. This is quite erroneous. It is the heredity cells that transmit, and the intimate mechanism of how these cells originate and how distribution and transmission are carried out by them up to fertilisation that is the question to be elucidated.

Progress in our exact knowledge has been, and is still being, retarded by the view, so long taken, of their origin from the epithelial cells covering the sex gland, from what is termed the germ or capsular epithelium, the cells of which are somatic. This view does not seem to be tenable now, although at one time no other was held. The histologist saw the heredity cells as oöcytes or ova in the female sex gland, and naturally when he looked about as to their source *within the ovary* the germ epithelium seemed the most likely one. When, however, *the whole* of the early developing organism was sectioned, certain travelling cells were found in the germ layer known as the inner or endoderm, and this gave quite a new source of origin for the heredity cells, as we shall see.[5] The origin of the heredity cells from the somatic cells of the germ epithelium I hold to be inconsistent with our present knowledge, although supported by many able histologists and much ingenious terminology.[6] It makes any explanation of heredity difficult and speculative, and, further, considers the heredity cells as originating from somatic cells instead of *vice versâ*.

The more correct view, supported by much and ever-increasing evidence, makes the heredity cells originate from an early division of the zygote This view may be put thus.[7] The zygote early in its development sets aside one part to form the "soma" of the individual, while at the same time a part is marked off, the primitive germ cell mass, to form the future heredity cells (ultimate ova and spermatozoa). While the somatic part is developing its germ layers, and before the genital ridges are developed on the Wolffian bodies to

[3] See the "Britannica Year Book," 1913. Pp. 299. Encyclopædia Brittanica Company. London. 1913.
[4] I use this as a simile. Many hold that their condition as compared with that of the queen is due to food. See "Phases of Evolution and Heredity," p. 145.
[5] This question has been worked out best in regard to the origin of the ova or oöcytes. We cannot say in an early embryo where the heredity cells are *en route* for the sex gland whether they will become oöcytes or spermocytes in it.
[6] See especially Bryce, Embryology, Quain's Anatomy (eleventh edition, p. 191), on von Winiwarter's views.
[7] The chief names associated with this view are Richard Owen, Eigenmann, Nussbaum, J. Beard, Lewis, King, Rubaschkin. See also Keibel's and Mall's Embryology, vol. ii., for Felix's article.

form with it the somatic part of the sex gland, the primitive heredity cells are travelling through the endoderm, like amœboid cells, and ultimately pass into the genital ridge when it has developed on the Wolffian body. The genital ridge and enclosed heredity cells with, in the male, certain Wolffian tubules now make up the sex gland. In fishes, frogs, birds, and mammals this migration is found, and the heredity cells can be stained and demonstrated. One observer, at least, Ingalls,[8] has found these travelling heredity cells in a 4·9 mm. human embryo (Urgeschlechtszellen he terms them without further comment) at the root of the mesentery on the mesial side of the Wolffian fold beneath the peritoneum there—i.e., they were not in the sex glands, which had not developed then, but travelling towards them. Thus, the heredity cells are not somatic, but *are an intrusion into the somatic part of the sex gland*, and are *in* it but not *of* it. They form a portion set aside and handed on from generation to generation, as Galton and Weismann suggested long ago under the terms "stirp" and continuity of the germ plasma.

THE DETERMINANTS OF HEREDITY.

According to Weismann and to the additions to our knowledge already given the somatic part of the zygote contains an id of determinants, the causal elements for the "soma" of the adult it will give rise to, and each of the heredity cells also an id. I must add, however, some interesting suggestions. We must regard the somatic portion as containing an id *plus* some directive and as yet unknown condition regulating the development of the somatic part to the adult form.

The determinants of heredity lie in the germ plasma in the form of "chromosomes" in the heredity cell nucleus. They are protoplasmic, and contain the immediate family qualities and those of recent and long past ancestors. The chromosomes are in the cytoplasm of the nucleus, and when we speak of the germ plasma we mean the former. In the ovum of the fœtal ovary and in the spermocyst of the fœtal testis they undergo mitosis (karyokinesis)—i.e., longitudinal and transverse splittings, and also in their minuter unknown particles, a circulation—all, I suggest, to give a variation of the determinants of heredity. Such variations follow the law of probability by which physicists now reckon the molecular movements of gases and emitted radium atoms, and thus we have to keep in mind not only that the determinants represent and are causal to the adult organs, but that this probability law, used in molecular physics to get at the results of such molecular movements, gives us an explanation of the probability curve which rules the groupings of height, length of bones, &c., in adults as expressed by biometricians.[9]

I must now mention a very striking phenomenon first discovered by van Beneden—namely, the "maturation" occurring at fertilisation when the gametes are formed from the approaching male and female germ cells prior to fertilisation. I have already stated that the heredity determinants are in the chromosomes. Each species of animal has its special number. In the round worm of the horse they are four, and changes in the number are thus easily seen. In maturation half of the chromosomes are lost, and thus in the approaching gametes in fertilisation in this worm each has only two. When the gametes unite for fertilisation the normal number for the zygote is made up—viz., four. This, then, means a reduction of heredity determinants on each side by one half, and thus we may have here a striking variation brought about for the future organism developed from the variation zygote. Mitosis thus gives a variation in determinants, expressed by a probability law, and results in the ordinary probability variations in offspring. In maturation we may get a striking variation, resulting in a marked variation in the progeny.

I now go on to consider briefly, on this preliminary basis, the work of Mendel.

MENDELISM.

Mendel's most easily understood crossing was that obtained by fertilising the stigma of a tall pea plant with pollen from a dwarf one, or *vice versâ*—it makes no difference in the result. The first generation were all tall and not intermediate in size, as would have been expected from any blending theory. This generation, self-fertilised, gave talls to dwarfs 3 : 1; of the talls one-third were true to tallness and two-thirds, now called impure talls, gave talls to dwarfs 3 : 1 again. The dwarfs, on the other hand, bred true to dwarfness throughout.[10] From this absence of blending of qualities in crossing experiments Mendel looked on the plant as made up of autonomous elements comprising height, colour, &c.—that is, of a large number of autonomous elements which became rearranged in a crossing, but in no way blended or counteracted. These are termed the autonomous unit characters in the adult plant or animal.

If we enumerate the results of such a crossing through several generations, as Mendel was the first to do, we get a probability result of 1 : 2 : 1—i.e., one of pure talls, two of impure talls, and one of dwarfs. The great results of Mendelism are: (1) the autonomy of unit characters; (2) the segregation of contrasted unit characters in a probability ratio; and (3) the fact that in a crossing with one contrasted character on each side one quarter of each is pure in the propagative part of the zygote, while one-half gives impure results—i.e., contains the two contrasted qualities in the pollen grains and egg cells.

Mendelism has thus brought great results into the mechanism of evolution, but one of these has not been logically pushed. If to the autonomy of the unit characters we add Weismann's idea of causal determinants in the zygote and gametes, we can then see that the autonomy of the unit characters may be considered as the result of the autonomy of the determinants. Further, changes or variation of unit characters can be brought about by probability changes in the determinants by means of mitosis and maturation.

The 1 : 2 : 1 probability result in plants Mendel discovered is thought by many to be the result of the combination of the pollen grains and egg cells in a tall-dwarf crossing. These, however, are merely the receptacles for the determinants, the analogue of the test tubes of chemical solutions which do not play any part in the equation of the chemist.

Most of you have heard of Mendel's theories of dominance and recession, and, indeed, from the prominence given to them you might be pardoned if you imagined that they were of supreme importance in Mendelism. They are, however, merely striking and metaphorical terms used by Mendel to explain one great fact in the first generation of the crossings (F^1) and this fact is as follows. In a tall dwarf crossing the plants of the first generation (F^1) are all tall, a great surprise to those who adhered to the blending theory. Mendel called the tall quality dominant and the dwarf recessive, expressing himself cautiously as follows: "The term 'recessive' has been chosen because the characters thereby designated withdraw or entirely disappear in the hybrids,[11] but nevertheless reappear unchanged in their progeny." From what has gone before it will be readily seen that the recessive quality "withdraws"—i.e., is distributed in the pollen grains and egg cells along with the dominant quality, but is not represented in the "soma" of F^1 plants. They should therefore be termed the first and second qualities, as the dominant is the first to be somatically and exclusively represented relative to dwarfism in F^1. There is no real dominance in tallness, as both tallness and dwarfness are distributed in a probability ratio in the pollen grains and egg cells of F^1 and afterwards in the same ratio in the plants themselves (F^1—F^n). This is no mere academic point, as attempts have been, and are being made by observers, myself among the number at one time, to classify the unit characters of the human body as dominant and recessive, and to allot to these, both in heredity and in diseased conditions, the power or representation, priority and otherwise, the terms express verbally. Nothing is gained in heredity by applying this theory after F^1, and all we can say is that in a T × D crossing one contrasted quality will be represented alone in the "soma" of the plants of F^1, but after that in F^2–F^n the distribution of the plants will be a probability one both in the pollen grains and egg cells and in the plant soma. One cannot use the

[8] Beschreibung eines Menschlichen Embryos von 4·9 mm., Archiv für Mikroskopische Anatomie, vol. lxx.

[9] Clerk Maxwell was the first to suggest that the molecular movements of gases in a closed space could be estimated by a probability law, and Arrhenius states that emitted radium atoms can be estimated by the same means. See the New Physics, by M. Lucien Poincaré, and also Arrhenius, Theories of Solutions, 1912, p. 33.

[10] The talls in every case are the same somatically. The pure talls have determinants for tallness in their pollen grains and egg cells. The impure talls have determinants for tallness and dwarfness together in their pollen grains and egg cells. The purity of gametes theory is quite erroneous.

[11] See in F^1, Bateson's Mendelism, p. 325.

idea of dominance and recession after the first generation, and thus as most of our results in human heredity are considered in generations subsequent to F^1 they are inapplicable in them.[12]

POINTS BEARING ON ANTENATAL EUGENICS.

The important points, then, to be considered as having a bearing on antenatal eugenics are: 1. The continuity of the germ plasma. 2. The origin of the heredity cells, not from the somatic cells covering the sex gland, but from an early division of the zygote. 3. The distributed and transmitted determinants of qualities giving rise to variation by means of the mitoses in the hereditary cells and their maturations prior to fertilisation, these processes being carrried out according to the law of probability. 4. Natural selection considered as an eliminant. 5. The autonomy of the unit characters, and therefore the autonomy of the causal zygotic determinants. 6. The probability result of the distribution of the determinants in the zygote by which each of the contrasted characters has a 25 per cent. chance of its pure distribution.

TRANSMISSION OF CHARACTERISTICS.

The sharp division made between soma and heredity cells raises the question—Can a somatic variation due to environment or accident be transmitted to progeny? Or, to put it more generally—Can acquired or induced somatic qualities be transmitted? From what has gone before it is evident that it is the germ plasma that transmits, and therefore any somatic or induced variation must have the power of influencing the germ plasma causally by placing determinants in it for its own transmission. No valid explanation of any such transference has been brought forward, and all of them are of a metaphorical nature. This is a most important point, as somatic disease in an adult, while it may infect the progeny in utero, does not if such progeny survive give rise to a race with this disease. Thus tuberculosis and syphilis, for example, are not hereditary diseases, a fact of the greatest moment to us. They are merely micro-organismal somatic diseases, and not hereditary in the strict sense.

One cannot counteract or obliterate or blend unit character determinants so as to get an intermediate or negative result. These determinants are autonomous and segregate in certain ratios. Thus they have their face value as in cards, and must be played out as such.

For the unit characters of the adult there are thus exact determinants in the germ plasma, and these are provided even for the most minute parts of the body. Many examples could be given, but one of them may be mentioned here in illustration. What is known as the Habsburg lip arose, according to Eimer,[13] as follows:—

> A very remarkable example is afforded by the large underlip of the Habsburgs. Portraits of Rudolf I. of Habsburg already show it. It was inherited by his descendants up till the last of them, the Emperor Charles the Sixth, 1740—that is, for five hundred years. With Charles the VIth the male line of the Habsburgers became extinct. Its place was supplied by the Thuringian line derived from the marriage of Francis of Thuringia with the Habsburger Maria Theresia. In the male descendants of this couple the great underlip appears again, and has been transmitted to the present day, although the wives of the Habsburgers, coming from various families, could not possibly by chance have generally possessed it, and did not possess it.

This is an interesting instance of a sex-limited transmission—i.e., of one present in one of the male gametes, in the Wolffian one—that is, in the one containing the Wolffian determinants for the somatic part of the testis, and therefore the transmission of the deformity. The female Habsburgers do not have it because the gamete from the male is a non-Wolffian one, that from the female a Wolffian one giving rise to the somatic portion of the ovary. Thus there is a special determinant for the lip shape, inconceivably minute as it must be, and no counteraction of it has taken place. Germ-plasma implanted determinants are transmitted in a probability ratio as Mendel showed, and biometricians have demonstrated that the numerical results of "organ" measurements, whether height in general, length of special bones, leaves of plants, &c., when separated out into similar groups give some form of frequency polygon.

[12] In certain first crossings between Anglo-Saxon and Eastern nations there is said to be a prominence of undesirable qualities in the first generation. The combined qualities may, however, be segregated afterwards, so that we may get a certain ratio of the desirable and undesirable combined qualities coming out, a certain number of them pure.

[13] Organic Evolution as the Result of the Inheritance of Acquired Characters. J. T. Cunningham's Translation. Macmillan and Co., London. 1890.

THE RELATIONS OF EVOLUTION TO DARWINISM, WEISMANNISM, AND MENDELISM.

Before going on further to practical results we must "orient" ourselves in regard to some points. Some of you may say, What relations have evolution as a whole, and the systems known as Darwinism, Weismannism, and Mendelism, to one another, and the last three to evolution?

Evolution is the great principle of progress of conditions in the universe, on this earth, and in all that precedes and pertains to man. Darwin, who is the greatest figure in the question of the mechanism of evolution, brought out results which are conveniently summed up as Darwinism. His followers have assigned three factors to it—variation, transmission of variation, and natural selection. Natural selection is, according to them, the great factor in producing variation. There is a fallacy, however, in all this—viz., the assumption that variation is mainly extrinsic. Darwin recognised that a somatic variation must be placed in the germ plasma, and therefore his theory of pangenism—i.e., of particles, gemmules, passing by the blood from somatic variations to the germ plasma, and thus giving causal agents there. Now it is here that Weismannism comes in. Weismann asserted the continuity of the germ plasma and the non-transmissibility of acquired characteristics; and the view due to others of the origin of the heredity cells from an early division of the zygote has demonstrated the accuracy of his suggestion.

Biometricians—Quetelet, Galton, Pearson—and others have shown that, to put it broadly, grouped facts as to bodily organs and functions and vital processes (deaths, crimes, births, organ measurements, labour in animals and man) give some form of frequency polygon, and Mendel made a striking contribution to this by his demonstration of a probability result in his famous experiments.

All these systems or contributions to evolution mechanism—Darwinism, Weismannism, Mendelism, the zygotic origin of the heredity cells, the fact of variation being intrinsic and brought about by means of molecular movements of the determinants in the heredity cells in the ovary and at the time of maturation—are steps in evolution research, and their judicious combination with many yet unknown additions will ultimately give the solution of how evolution in its broad sense has been brought about. If, on the other hand, we consider the heredity cells as having a somatic origin from the germ epithelium, we look on the body of man as purely somatic in its nature, and thus lose Weismann's and Galton's great generalisation of the continuity of the germ plasma. If in addition to this we do not accept the zygotic origin of the heredity cells we are deprived of a real means of explaining transmission and distributing qualities in heredity. It is the assumption that variation is mainly extrinsic that is hindering progress in our knowledge of this vital question.

The important antenatal changes in the heredity cells prior to fertilisation are thus intrinsic in the germ plasma and beyond any direct influence. It is well to bear this in mind, as optimistic eugenists often forget this and raise hopes as to what may be done by eugenics in quite an unjustifiable way. It is to postnatal eugenics that we must look for much valuable progress, but in antenatal eugenics the power of the eugenist is much more limited, and he has to accept, not absolutely but nearly so, the fate determined by the continuity of the germ plasma and the intrinsic zygotic and fertilisation changes occurring prior to and at conception.

GROUPING OF CONDITIONS.

We may group abnormal human conditions due to intrinsic germ plasma conditions and distributions as follows: 1. Those inherent in the germ plasma determinants and subject to ordinary variations and distribution. 2. Those that are due to loss of determinants at maturation and are therefore characterised sometimes by a striking manifestation of deformity. They are thus mutations in de Vries' sense. Of these there are two classes relative to transmission—(*a*) those limited to one sex; (*b*) those occurring in both sexes.

1. *Inherent in the Germ Plasma.*

From these we get the neurotic strain, insanity, imbecility, and other minor and major degeneracies. The germ plasma can probably become degenerate, and it is quite possible that persistent alcoholism in

a series of generations may injure its quality. Goldmann's[14] valuable intravitam injections of animals show, however, that the isamin blue stain affects the membrana granulosa cells, but not the ovum itself. The peculiar imbecile known as the Mongolian is apt to occur late in the childbearing period of a mother, and is of a very characteristic type. The children, however, of persistent alcoholics, on one side usually, may be unaffected, as no doubt many of you have seen.

Germ plasma is most frequently weakened by the marriage of a degenerate with a healthy stock, and this is manifested by the occasional appearance of degenerates in the subsequent progeny. Of this Ireland, in his "Blot upon the Brain," gives an interesting example in the unfortunate insanity of Louis II. of Bavaria, the patron of Wagner and a man of high artistic perception. This was introduced into the Royal family by the marriage of Maximilian II. to Mary of Hohenzollern, daughter of the youngest son of Frederick William II. of Prussia. Ireland's studies of royalties in this respect gives many instances of similar disasters in the Romanoff and Spanish dynasties.[15]

2. *Due to Loss of Determinants.*

Some hereditary abnormal conditions are (*a*) sex limited and not present in the "soma" of the transmitters. This shows how one must keep in mind the division of the body into "soma" and heredity cells. *Hæmophilia* is not expressed in the body of the mother who transmits it to her son, but in her heredity cell. The explanation of the sex limitation in this case and others similar to it is difficult, is bound up with the question of double gametes on each side at fertilisation, but time forbids discussion. The hæmophilia may be considered as due to the loss of the determinant for the clotting power of the blood at maturation and is thus a mutation. This will be seen more clearly under head (*b*).

(*b*) The abnormal and often transmissible qualities not limited to sex are more numerous than those under (*a*), and two striking illustrations are given in brachydactyly and achondroplasia. Here as in hæmophilia the condition is an exact one.

In *brachydactyly* it is the middle phalanx of the fingers and toes that is undeveloped, being only represented by a nodular cartilage ankylosed to the first phalanx (Drinkwater's skiagrams).[16] This deformity owes its origin, I believe, to a loss of the growth determinant for these phalanges when the polar bodies are thrown off. It thus occurred suddenly in this deformity, and its transmission ratio is 50 per cent. sound and 50 per cent. brachydactylous. The condition is not counteracted by the sound member. Brachydactyly is termed a "recessive," but this throws no light on its nature any more than if it were termed "mesopotamic." If present in one gamete and absent in the other we get a "head and tail" result, 50 per cent.

In *achondroplasia* we have defective growth of the bones developing in early endochondral ossification (Alexis Thomson and Symington)[17] in the base of the skull, ribs, limbs, pelvis, and we thus get a short-legged, short-armed variety of men and women, with characteristic insinking of the nose, trident hands, and deformed pelvis. This is transmitted, as it must be, seeing it is probably a polar loss from one heredity cell.

I am making up a list of all the organs in the body that may not be present in individuals often otherwise healthy and capable, and find that every bone in the body, large parts of it (limbs, for instance), certain muscles (especially the pectoralis major), certain parts of the brain (corpus callosum), many organs (kidney, half of the urogenital system, parts of the genital tract) may be awanting. For such a condition nothing can be done,[18] nor can it be prevented.

THE QUESTION OF MARRIAGE.

The guiding and practical principles of this subject of antenatal eugenics may now be taken up.

The first thing to be emphasised is the importance of "strain" in a family. Where there is a neurotic history and a tendency to nervous breakdown in its minor and major aspects the question assumes great importance. Not only do men and women with a marked heredity of insanity intermarry, but, as we all know, may do so without hesitation after a marked attack. There is no doubt this is unwise and may bring a terrible retribution, but how few follow the example of John Smith, the assistant master of Harrow, whose life has been so simply and beautifully recorded lately.[19] All medical men interested in this—and who are not?—should read it for its example of self-denial and the lessons it teaches. It must be noted here that the immediate parental qualities only give an indication of what may be served out in the progeny, and that there may be variations often in sharp contrast to the parental and traceable back to immediate blood relations and even to more remote ancestors.

The medical man should deprecate strongly any marriage where there is a marked neurotic strain on both sides. When on one side only, the healthy side should be that of a sturdy, solid stock. In after generations the same should be done, in this way swamping unhealthy determinants. It should not be considered that one is in this manner antagonising the bad strain, but reducing its production ratio to the healthy new one. Degeneracy, like murder, will out. Such advice, however, is more difficult to give in practice than here, and indeed many who need it do not ask for it, and are unable to grasp its necessity.

As we have seen, some hereditary abnormal conditions are sex-limited and not present in the soma of the transmitters. This shows how we must keep in mind the division of soma and heredity cells.

LEGISLATION AND EDUCATION.

The question of actual prevention of undesirable unions comes up further in the cases of imbeciles or of undesirables who breed criminals. These are a great problem to the eugenist, and strong proposals have been made—the removal of the sex glands or the entire prevention of their marriage. In America especially many such proposals have been made, but these have not been received with any enthusiasm, and do not appeal to one's common sense as being practicable.

It indeed has been suggested that all marriages should only be allowed when there is a clean heredity bill and absence of disease in the case of both contracting parties. In our own country the passage of the Mental Defectives Bill appears to be a step in the right direction, but results have yet to come and be studied.[20]

It is really the people who must be educated in a Disraelian sense; and as Disraeli had to educate his party, so eugenists must spread sane views on such questions among the laity. This is the only safe and rapid method. The public respond quickly to sound teaching and soon start a propaganda among themselves. This is well seen at present in the case of the prevention of tuberculosis, where the preventive measures insisted on by experts are widely followed. How soon ideas diffuse among the laity is shown by the widespread use (all over the civilised world) of means for the prevention of conception, especially among the well-to-do, and the consequent universal and serious fall in the birth-rate. The tenets of Malthusians have become well established in little more than a generation.

Eugenists must take advantage of this lever and insist that to have sound progeny there must be sound parents and ancestors and a healthy post-natal nurture. How far we are from such an ideal need not be said, but how much may ultimately be done by medical men in settling safety in marriage is shown by the discovery of the Wassermann reaction. Apart from the deadly influence of syphilis on the infected man and woman and their offspring, it is now known that it has a greater effect in producing imbecility than was at one time thought. Here, then, is a specific test which could be applied prior to marriage in the case of one of the contracting parties giving a history of syphilis.

CONCLUDING REMARKS.

The future of the science of antenatal eugenics and its practical applications is a great one If investigation on biometric lines is carried out as is being actively done at

present, we may have such an accession of facts that we may be able at least to predict not any single actual result in heredity, but a probable grouping of such. Thus, if we accept Weismann's view of the representation of bodily structure of function by means of determinants in the heredity cells, and if we combine with this Mendel's discovery of the autonomous unit characters as making up bodily structure, adding to it, as I have done, the idea of autonomy of the determinants and their variation in the heredity cells by mitosis and maturation prior to fertilisation, we may then ask, Can we not settle what and how many are the possible causal determinants in man? This may be worked out as follows. If one takes such books as Ballantyne's "Antenatal Pathology" and Schwalbe's "Missbildungen," and the many X ray skiagrams we have of deformed conditions as well as all the records of such in our various journals, we find an enormous number of exact deformities—i.e., of losses of groups of unit characters representing bones organs, muscles, &c., awanting; and if we add to them the exact losses in the normal female genital tract as compared with the male, we can by such facts and by analogies construct a series of determinants for the unit characters—i.e., organs, &c., of the body. If now we could select, say in a series of three generations, all the determinants of the qualities represented in them, we would obtain a large series of statistics capable of biometric analysis. This may seem a chimerical idea, but it is on Galton's lines—and I am convinced it is the right one—of inquiry. In the future the careful study by means of molecular physics of mitosis and maturation, of the facts of Weismann's and Mendel's great work, and the extended use of biometric methods, will give, I have no doubt, an actuarial value to heredity investigation which it as yet only in part possesses.

The present generation of medical men has received from some of its great predecessors—Simpson, Lister, Pasteur, Koch, to name the dead immortals only—an immense accession of knowledge, and in our daily practice and investigations we unconsciously pay a tribute to their genius. Future generations will be still more in the debt of the great evolutionists—Lamarck, Darwin, Wallace, Weismann, Mendel, Galton—who have laid the foundations of our knowledge of evolution and eugenics, so that the future of our race may be that of one whose ideal is *Mens sana in corpore sano.*

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.—The first meeting of the new session of this society took place in the board room of the Great Northern Hospital on Oct. 9th, Dr. T. Wilson Parry, the President, being in the chair. Sir George Savage gave a most interesting and entertaining lecture on the Mental Diseases of Old Age. He referred to the degenerations of old age as regards memory, loss of control, sexual perversions, and defect of will, and illustrated his lecture with anecdotes of cases, which he rendered in a most dramatic manner. A hearty vote of thanks was given to the lecturer, a compliment which Sir George Savage suitably acknowledged.

ALVARENGA PRIZE OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.—The College of Physicians of Philadelphia announces that the next award of the Alvarenga prize, being the income for one year of the bequest of the late Señor Alvarenga, and amounting to about $180, will be made on July 14th, 1914 provided that an essay deemed by the committee of award to be worthy of the prize shall have been offered. Essays intended for competition may be upon any subject in medicine, but cannot have been published. They must be typewritten, and if written in a language other than English should be accompanied by an English translation, and must be received by the secretary of the College on or before May 1st, 1914. Each essay must be sent without signature, but must be plainly marked with a motto and be accompanied by a sealed envelope having on its outside the motto of the paper and within the name and address of the author. It is a condition of competition that the successful essay or a copy of it shall remain in possession of the College; other essays will be returned upon application within three months after the award. All communications should be made to Dr. Thomas R. Neilson, 19, South 22nd-street, Philadelphia, U.S.A.

An Address

ON

THE CEREBRO-SPINAL FLUID IN HEALTH AND DISEASE.

Delivered before the Medical Society of London on Oct. 13th, 1913,

BY SIR DAVID FERRIER, M.D., F.R.S.,

PRESIDENT OF THE SOCIETY.

GENTLEMEN,—In casting about for a subject bearing on practical medicine on which I might address you on this occasion, it occurred to me that it might be of some interest to you as practitioners if I made some remarks on the cerebro-spinal fluid in health and disease. This is a subject which in recent years has assumed great importance, more particularly from a diagnostic point of view, but there are other aspects bearing on the symptomatology of cerebral disease which, I think, are also worthy of consideration.

Let me first remind you of some preliminary anatomical details. The cerebro-spinal fluid occupies the ventricles of the brain, and the subarachnoid spaces of the brain and spinal cord—all these being continuous with each other, so that normally there is free communication throughout. The chief passages between the ventricles and the subarachnoid space are the foramen of Magendie at the apex of the fourth ventricle, and the foramina of Luschka at the external lateral recesses of the same ventricle. The existence of the foramen of Magendie has been questioned by some anatomists, but I think that the balance of evidence is in favour of it being a natural formation, and not a mere artefact as has been contended.

The spinal arachnoid is a relatively large space and forms a sac round the cauda equina, where it can be conveniently punctured, and its fluid evacuated by the usual method of lumbar puncture. On the surface of the brain the arachnoid does not, like the pia mater, follow the exact outline of the surface, but bridges over the anfractuosities, so that in certain situations considerable spaces are formed, constituting the cisterns, which are filled with cerebro-spinal fluid. A spongy reticulum of areolar tissue covered by endothelium separates the arachnoid from the pia mater, so that the fluid fills these like the meshes of a sponge. This reticulum is continuous with the perivascular lymphatic sheaths which accompany the cortical vessels till they break up into capillaries. The perivascular sheaths are therefore continuous with the subarachnoid space, or may be said to open into it. And Mott,[1] from his examination of the brain in sleeping sickness and experimental cerebral anæmia, has given good grounds for believing that the perivascular sheaths are continuous with similar spaces surrounding the nerve cells; so that we have a system of canals continuous, on the one hand, with the pericellular or perineuronal spaces, and, on the other hand, with the subarachnoid space. (In this he is confirmed by the recent *intra vitam* staining experiments of the late Professor Goldmann.[2]) These, no doubt, play an important part in the nutrition of the brain cells—probably forming the medium of interchange between them and the blood in the capillaries—giving up water and carbon dioxide, and taking up oxygen and sugar. The question, however, cannot yet be considered as settled, as His, Sicard, and others believe that the true lymph channels of the brain are separate from the perivascular sheaths of Robin.

Of greater importance, from a pathological point of view, is the fact that the subarachnoid space is continuous with the sheaths of investment of the cranial and spinal nerves, and

[1] Oliver-Sharpey Lectures, THE LANCET, July 2nd (p. 1) and 9th (p. 79), 1910.
[2] THE LANCET, July 12th, 1913, and Brit. Med. Jour., Oct. 4th 1913.

through these enter into communication with the peripheral lymphatics, thus furnishing a means of entry of organisms and toxins into the central nervous system, a source of infection which the researches of Marie and Guillain,[3] and those of Orr and Rows,[4] have shown, may serve to explain among others the degeneration characteristic of tabes. For in the spinal and cranial nerves and nerve roots there is a lymphatic system in the perineural sheath continuous with the lymph spaces of the pia-arachnoid, and as the main current is towards the centres, and particularly along the posterior roots, organisms and toxins can be conveyed in this manner and exercise their specific influence on the parts with which they come in contact.

The lymphatics of the nasal mucous membrane can be injected from the sheath of the olfactory nerve. The subvaginal sheath of the optic nerve is continuous with the subarachnoid space, and coloured particles injected into the subarachnoid space form a distinct ring at the lamina cribrosa, where the nerve enters the sclerotic. Though there appears to be no direct communication between the cerebro-spinal fluid and the perilymph, yet the subarachnoid space is in relation with it by means of the aqueductus cochleæ.

The cerebro-spinal fluid is being continually secreted, and is continually escaping. Various estimates have been made of its average amount in normal conditions, but probably none are quite accurate. It does not exceed a few ounces at most. If allowed to escape it is secreted more copiously, and many cases have been reported[5] of the spontaneous escape of cerebro-spinal fluid from the nostrils to the extent of several litres a day. The same thing may be observed after fractures of the base and after operations for the removal of cerebral tumours, where the dressings are continuously soaked for many days or weeks. If by any chance the fluid is secreted in larger amount than normal or its escape hindered, various pathological conditions arise, to some of which I will refer subsequently.

The cerebro-spinal fluid escapes both by the lymphatics—constituting, according to Cathelin, a kind of subsidiary circulation[6]—and by the veins, but the chief exit, as has been shown by the experiments of Leonard Hill, is the venous sinuses of the dura mater. Salt solution injected into the subarachnoid space at any pressure above the normal venous pressure speedily disappears from the cranio-vertebral cavity—the higher the pressure the more rapid its disappearance. Saline coloured with methylene blue can be seen passing straight into the venous sinuses; and in so short a time as from 10 to 20 minutes the blue colour may be seen in the stomach and bladder. On the other hand, the lymphatics in the neck are in this time not even coloured. After an hour's injection, however, the lymphatic glands begin to assume a bluish tinge. It is held by Key and Retzius that the escape takes place by way of the Pacchionian bodies or glands, which are merely polypoid proliferations of the subarachnoid tissue, which insert themselves into the venous sinuses of the dura mater and diploë. Cushing, however, is of opinion that there must be more direct communication between the subarachnoid space and the longitudinal sinus, as the Pacchionian glands do not exist in the very young or in some of the lower animals.

Most physiologists, since the researches of Pettit and Gerard (1902), are agreed that the cerebral-spinal fluid is secreted by the choroid plexuses. The villosities of the choroid plexus are covered by a layer of cubical or spheroidal epithelial cells which, under the influence of agents which stimulate secretion, are seen to undergo changes indicative of a transformation of the distal portion of the cells into globules which merge with the fluid in the ventricles. These, as the recent experiments of Goldmann have shown, consist largely of glycogen, an important element in the building up of nerve tissues.[7] And Mott has demonstrated the presence of nerve fibrils surrounding the blood-vessels of the villi, which are probably secretory in function. The secretion is stimulated by certain agents, such as the volatile anæsthetics, and by pilocarpine (counteracted by atropine), but especially, as has been shown by Halliburton and Dixon,[8] by extracts of the choroid plexus itself, and also to some extent by extract of brain matter. But though the cerebro-spinal fluid is obviously a secretion, the cells of the choroid plexus offer remarkable resistance to the passage into the fluid of most substances that may be introduced into the circulation. Urotropin, chloroform, and alcohol are among the chief exceptions. On the other hand, drugs and toxins are absorbed from the cerebro-spinal fluid, and produce their characteristic effects with as great (if not greater) rapidity as when introduced directly into the circulation.

The cerebro-spinal fluid, under ordinary conditions, is a clear fluid of low specific gravity—this being on the average from 1·006 to 1·008. It is practically free from corpuscular elements, and contains only traces of proteid in the form of globulin, becoming only slightly turbid on heating. It has an alkaline reaction, but the alkalinity is only half that of the blood. The principal constituent is sodium chloride, and there are traces of carbonates, phosphates, urea, and dextrose. Its composition, however, as withdrawn by lumbar puncture, is no doubt different in some important respects from that at the moment of its secretion by the choroid plexus. In particular, as has been shown by Cushing and Goetsch,[9] the cerebro-spinal fluid contains pituitin, the secretion of the pars nervosa or intermedia of the pituitary gland. This, as I may remind you, is poured into the infundibulum, and thus finds its way into the third ventricle. Cushing and Goetsch have found that concentrated extracts of the ventricular or lumbar fluid cause all the characteristic reactions of pituitin—viz., rise of blood pressure, diruresis, and dilatation of the pupil.

The cerebro-spinal fluid, therefore, besides being the medium of interchange between the blood and the nerve cells according to Mott's hypothesis, would thus be the means of bringing the active principles of the secretion of the pituitary gland into immediate contact with the cerebro-spinal tissues.

As to the mechanical effects subserved by the cerebro-spinal fluid, some are normal, others are concerned in the genesis of various pathological conditions. The brain substance, with its blood and cerebro-spinal fluid, completely fills the interior of the cranial cavity. Being removed from atmospheric pressure and practically incompressible, it can make room for each systolic accession of arterial blood only by diminution in the quantity of venous blood or cerebro-spinal fluid, or both. Each pulsation is distributed uniformly throughout the whole mass by the cerebro-spinal fluid, and the pulsations can be seen and registered by appropriate apparatus at the occipito-atlantoid ligament.

The intracranial tension varies directly with the venous pressure, so that as this varies with inspiration and expiration these phases are well marked—expiration raising the tension and inspiration lowering it. The tension of the cerebro-spinal fluid is, therefore, ever varying more or less. It averages about 100 mm. of water, and when being drawn off by lumbar puncture it can be seen to spurt out with each muscular or expiratory effort.

The cerebro-spinal fluid thus acts as a distributor or equaliser of pressure throughout the whole intracranial cavity. Whether it also acts as a sort of water-cushion to protect the brain against shocks, as is generally supposed, is more than doubtful. There is less fluid relatively at the apex of the temporal lobes than at the cisterns at the base of the brain, yet here jarring or concussion is more likely to occur than there.

The same conditions which lead to the uniform transmission of the normal increase of arterial tension explain the effects of sudden or gradually increased pressure on the brain. As has been shown by Duret,[10] when a trephine opening is made in the skull, and pressure made with the tip of the finger on the exposed hemisphere, the occipito-atlantoid ligament is seen to bulge, and all pulsation stops. The pressure drives the cerebro-spinal fluid out of the lateral ventricle and down into the fourth ventricle, where it tends to escape into the subarachnoid space. If the pressure is sudden or intense, such as may be caused by a severe blow on the elastic skull or by the rapid injection of a non-absorbable substance, the cerebro-spinal fluid may be displaced with such force as to rupture the walls of the

iter and fourth ventricle, and cause extensive capillary extravasations here and in the brain generally by damming back the cerebro-spinal fluid into its remotest rivi, rivuli, and perivascular sheaths.

In a similar manner may be explained the suddenly fatal consequences of bullets of high velocity traversing the brain, which, as Horsley and Kramer[11] have shown, kill by the disruptive pressure they exercise on the centres of the medulla oblongata and consequent stoppage of respiration.

Slowly increasing pressure, such as is brought about by the growth of intracranial tumours, and especially such as are so situated as to obstruct the free flow of the cerebro-spinal fluid, lead to increased tension, as shown by the way in which it spurts out on lumbar puncture in most cases of cerebral tumour. It is this pressure propagated into the intravaginal sheath of the optic nerve which, as I think has been conclusively shown by Paton and Gordon Holmes,[12] is the cause of the papillœdema or so-called optic neuritis which is so characteristic of intracranial tumours. Various theories have been propounded as to the pathology of this condition. It has been attributed to pressure on the cavernous sinus; to inflammation caused by toxins generated by the tumour; to vaso-motor influence; to descending neuritis or perineuritis, to all of which views valid objections can be made. The histological investigations of Paton and Holmes have shown that there is no inflammation properly so-called, as none of the characteristic products of inflammation are present. The mechanism is undoubtedly the increase of the intravaginal sheath pressure propagated to the lamina cribrosa, which strangles the central vein and lymphatics of the retina, thus leading to venous congestion and lymph stasis, with swelling and, it may be, hæmorrhages in and around the papilla. The condition is one of papillœdema and not of neuritis.

Another interesting indirect result of increased tension of the cerebro-spinal fluid has been described by Batten and Collier.[13] In many cases of cerebral tumour, wherever situated, degeneration occurs in the posterior columns of the spinal cord, often with symptoms simulating tabes—viz., absence of arm and knee jerks, and in some cases hypotonia, shooting pains, and ataxy. It has been difficult to find a satisfactory explanation of these facts. Batten and Collier, with, I think, good reason, attribute this degeneration to the injurious traction exerted on the posterior roots by the distension of the arachnoid from increased fluid pressure, and especially such as tends to cause rapid dilatation of the ventricles and of the subarachnoid space. From the position of the posterior roots, and their attachment to the arachnoid, these are especially dragged upon, and in consequence degeneration occurs in their intraspinal prolongations. In the further course of gradually increasing cerebral compression, in addition to these indirect effects, we observe a local ischæmia and ultimate destruction of the parts immediately invaded, with a general rise of intracranial tension till the pressure becomes equal to arterial pressure. When this stage is reached the cerebral circulation comes to a standstill, with failure first of the functions of the hemispheres, and last of the vital centres of the medulla oblongata, respiration failing before circulation.

In certain conditions not well understood, as in congenital hydrocephalus, and so-called serous meningitis, the cerebro-spinal fluid is secreted more rapidly than it can escape, or its escape is altogether prevented by blockage of the foramina of Magendie and Luschka. As a result we see the enormous distension of the cerebral ventricles, enlargement of the head, and the other phenomena, physical and mental, with which you are all familiar in congenital hydrocephalus. Whether this is due to increased secretion or blockage of the outflow, or both, is a question, but I agree with Guthrie[14] in thinking that all three causes may be at work. In some cases hypertrophy of the choroid has been found, indicating the possibility of increased secretion; while in others the fluid, though usually of normal composition, resembles inflammatory effusion.

Apart from congenital cases, meningitis at the base or obstruction of the aqueduct of Sylvius is the most frequent cause of secondary hydrocephalus. The most common situation of tumours which have this effect is in the cerebellum or brain stem, but tumours situated elsewhere and reaching any considerable size may also block the outflow by pressing the cerebellum and pons down into the foramen magnum. And one often sees how readily the general symptoms of non-operable tumours of the brain-stem—the somnolence, the hebetude, headache, &c.—can be relieved by puncture of the distended cerebral ventricles and free outflow of the cerebro-spinal fluid.

As regards the serous meningitis of Quincke, Bonninghaus, and others, it is assumed that apart from inflammation the cerebro-spinal fluid may in certain conditions, similar to angio-neurotic œdema, be poured out in such quantity as to constitute an internal or external hydrocephalus. The pathology of this condition is still obscure, but certainly many of the cases of so-called serous meningitis arise in connexion with otitis media and are obviously of inflammatory origin, though the fluid may have none of the characteristics of inflammatory effusions. And the fact that bacilli of various kinds have been found in the fluid obtained by lumbar puncture in some of the cases would render their non-inflammatory nature extremely doubtful.

But in others all signs of inflammation are absent, and the condition is of importance from a practical point of view, as it may simulate cerebral tumour, specially of the cerebellar type, and lead to operations for removal or for purposes of decompression. Fortunately, the relief of the tension by such procedure is often followed by the happiest results.

Since the introduction of lumbar puncture by Quincke in 1891 the examination of the cerebro-spinal fluid by this method is carried out daily even in ordinary out-patient practice, but perhaps less frequently here than abroad. Though when performed with all proper precautions it is, as a rule, without risk, causing at most only trifling malaise within the next 24 hours, yet in some cases, especially in tumours of the posterior fossa, it may be dangerous, and already a good many cases of death have been reported under such circumstances. It is probable that in these cases the rapid withdrawal of a considerable quantity of liquid has led to a jamming down of the brain stem into the foramen magnum and compression of the vital centres of the medulla oblongata.

Much may be learnt from the way in which the cerebro-spinal fluid drops, flows, or spurts from the needle; from its appearance, whether clear, turbid, or blood stained, but more from its chemical and microscopical examination. Since the introduction of the cytological examination of the cerebro-spinal fluid by Ravaut, Sicard, and other French observers, and the discovery of the Wassermann reaction for syphilis, the cytological and chemical examination of the cerebro-spinal fluid has assumed an unusual degree of importance, more particularly in reference to the differential diagnosis of syphilitic and so-called parasyphilitic affections. It is on this question that I specially wish to confine my further remarks.

As has been previously stated, the cerebro-spinal fluid in normal conditions is practically free from corpuscular elements—only from 1–5 lymphocytes being seen in the centrifugalised deposit in the ordinary microscopical field. But in certain forms of disease the corpuscular elements are present in greater abundance and of different forms. In acute microbic affections of the cerebro-spinal meninges, as by staphylococcus, pneumococcus, diplococcus intracellularis, and others, a leucocytosis occurs in which the leucocytes are mostly of the polynuclear type, and the organisms may also be seen, or cultivated in the usual way. On the other hand, in certain more chronic affections of the meninges, as in tubercle, trypanosomiasis, and syphilis, an excess of leucocytes also occurs, and these are mostly of the mononuclear type—in other words, there is a lymphocytosis or pleocytosis. The tubercle bacilli and trypanosomes can also usually be detected, but hitherto the spirochaeta pallida has not been found, in its ordinary form at least. A similar excess of lymphocytes has also been detected in herpes zoster, Landry's paralysis, subacute combined degeneration, and occasionally in disseminated sclerosis, and is generally regarded as a sign of irritation or inflammation of the meninges.

The pleocytosis of cerebro-spinal syphilis, tabes, and general paralysis is often a very early occurrence, and may be found before any of the characteristic signs or

[11] Proceedings of the Royal Society, 1894.
[12] Brain, vol. xxxiii., 1910.
[13] Brain, vol. xxxii., p. 488.
[14] Hunterian Lecture, Remarks on Hydrocephalus, Practitioner, July, 1910.

symptoms of these affections. Hence its great diagnostic value.

In the diagnosis of parasyphilitic affections great reliance is placed on what are termed in Germany the four reactions. These are: First, the Wassermann reaction in the blood. In florid syphilis and in cerebro-spinal syphilis, as well as in tabes and general paralysis, this is practically constantly positive. The second of the four reactions is what is termed Phase 1—i.e., an excess of globulin in the cerebro-spinal fluid. This is determined usually by the Nonne-Apelt method, which consists in mixing the cerebro-spinal fluid with a saturated solution of ammonium sulphate. An opalescence, or turbidity, of the fluid indicates an excess of globulin. This always occurs in tabes, general paralysis, and cerebro-spinal syphilis, and though it may be found occasionally in other conditions, such as spinal tumour and encephalomalacia, yet in combination with the Wassermann reaction of the cerebro-spinal fluid and pleocytosis it has been regarded as practically pathognomonic of parasyphilis. The third of the four reactions is the pleocytosis of which I have already spoken. The fourth is the positive Wassermann reaction of the cerebro-spinal fluid. The frequency of this has been variously estimated by different observers, but the most recent investigations by improved methods (Hauptmann's Auswertungs-Methode) have shown that at least 95–100 per cent. both of tabes and general paralysis give a positive reaction; and the probability is that with improved technique the exceptions will become still fewer, and that in all cases of parasyphilis the Wassermann reaction of the cerebro-spinal fluid will be found positive. In cerebro-spinal syphilis, however, there is great divergence of opinion as regards the reaction in the cerebro-spinal fluid. It is commonly stated (Plaut, &c.) that in cerebro-spinal syphilis, whether the brain or cord is affected, whether the process is acute or chronic, whether the lesion is a gumma, endarteritis, meningo-encephalitis, or meningo-myelitis, the reaction is uniformly negative. In the rare cases—not more than 6 per cent.—in which a positive reaction occurs, the reaction is slight and contrasts markedly with the positive reaction of the blood serum.

The most recent research on this subject, however, by Head, McIntosh, Fildes, and Fearnsides,[15] has shown that in cerebro-spinal syphilis when the cord is obviously involved, a positive reaction is obtained in 21 out of 23 cases—i.e., in 87 per cent. It would thus appear that all the four reactions may be found in tabes, general paralysis and cerebro-spinal syphilis, and that one cannot, as has been hitherto supposed, accurately differentiate syphilitic from parasyphilitic affections of the nervous system by this method.

The great test is the therapeutical one. Whereas in cerebro-spinal syphilis mercurial or salvarsan treatment will in the great majority of instances convert the positive reaction of the cerebro-spinal fluid into negative, in parasyphilitic affections—tabes and general paralysis—this is of no avail.

The question is whether the impotence of our therapeutic measures constitutes a valid or essential distinction between syphilitic and parasyphilitic affections. I need not here discuss the various hypotheses which have been propounded as to the nature and genesis of the parasyphilitic toxin. It has long been recognised that the generally progressive nature of cerebral and spinal tabes must postulate the continued generation of some toxin, and the fact that the blood and cerebro-spinal fluid yield the same reaction as that characteristic of syphilis proper has naturally suggested the continued presence of the spirochæte itself. Many, however—myself and my colleague Dr. Emery among the rest—have in vain looked for the spirochæte in the tissues of the body; but the recent discovery by Noguchi and Moore, confirmed by Marie, Mott, and others, of the spirochæta pallida in the substance of the brain and spinal cord of undoubted cases of general paralysis and tabes, though hitherto only in relatively small percentages, seems to have obliterated the last distinction between syphilis and parasyphilis.

How, then, are we to account for the differences between parasyphilitic and syphilitic lesions, and the curative influence of antisyphilitic remedies in the one case and not in the other? It has been supposed by Mott, and I have myself adopted the same view, that parasyphilitic lesions of the nervous system are essentially of a primary parenchymatous degenerative nature, the changes in the neuroglia and lymph channels being only a secondary result of this process. Head and his colleagues, however, maintain that there is no essential difference between the two processes. They regard both parasyphilitic and syphilitic lesions as a reaction to the same toxic influence—in the one case the reaction occurs in the nerve cells and neuroglia, in the other in the meninges and the vessels. "Parasyphilis of the brain and cord, therefore, corresponds to the parenchymatous lesion of the testicle (so-called parasyphilis of the testicle), while the gummatous lesions of the brain correspond to gummatous (interstitial) orchitis." They liken the reaction of parasyphilis to that of tissues rendered hypersensitive, anaphylactic, or "hyperallegic" by previous infection. Gummatosis is the reaction of hypersensitive vessels and connective tissue which undergo proliferative changes, while parasyphilis is the reaction of hypersensitive nerve elements which have no power of regeneration and therefore break down. The pleocytosis, globulin, and Wassermann reaction of the cerebro-spinal fluid are all indications of the affection of the meninges, and breaking down of the essential elements of the nerve centres.

As there is a more or less continuous generation of the toxin by the continuous presence of the spirochæta pallida in the substance of the brain and cord and perhaps elsewhere, the process tends to be progressive. The most probable explanation of the failure of antispecific treatment to arrest the disease is that the remedies usually employed, such as salvarsan injections, mercurial inunctions, &c., fail to reach the spirochætæ embedded in the nerve tissues. We have already seen that few substances can pass out of the blood into the cerebro-spinal fluid. And Wilcox has found that after treatment by salvarsan, though all the viscera contained large quantities of arsenic, there was no trace of it in the brain.

This naturally leads me to the consideration of another aspect of lumbar puncture on which I have not yet touched—viz., the therapeutical. Hitherto the benefits of lumbar puncture to medicine from a therapeutical point of view have been overshadowed by their diagnostic value. Beneficial results as regards the reduction of intracranial pressure have been reported in cases of hydrocephalus, serous meningitis, and cerebral tumours, but they have not been so marked as to lead to any very general adoption of the method; and in some forms of cerebral tumour, as I have already indicated, the procedure is not free from risk. In many cases of infectious meningitis, other than tubercular, improvement has resulted from lumbar puncture; and the headaches of chlorosis, migraine, syphilis, uræmia have been relieved, as well as the symptoms of Ménière's disease. The injection of cocaine into the spinal subarachnoid for the purposes of producing paraplegic anæsthesia, and the injection of magnesium sulphate in order to allay tetanic spasms, and similar procedures, are familiar to you, and it is not my intention to describe them in detail or discuss their relative advantages or demerits.

I should just like to express the opinion that in those forms of disease which are not accessible to remedies conveyed by the blood stream the only hope of success seems to lie in bringing the antispecific into immediate contact with the organisms which are the cause of the disease. We have seen that the remedies which are all powerful against the spirochæta pallida are incapable of passing from the blood into the cerebro-spinal fluid, while the spirochætæ flourish in the perivascular and pericellular spaces which communicate with the subarachnoid space. It seems, therefore, a rational procedure, and one supported by the brilliant results obtained by Flexner[16] and others in the treatment of cerebro-spinal, influenzal, and pneumococcal meningitis, to introduce into the cerebro-spinal fluid, if it can be done with safety, some of the agents which we know to be fatal to these organisms, in the hope that they may thus be brought into immediate contact with them. Salvarsan, however, cannot be safely injected into the spinal subarachnoid space, except in extreme and probably ineffective dilution. But at the recent meeting of the International Medical Congress Homer Swift, of the Rockefeller

[15] Parasyphilis of the Nervous System, Brain, vol. xxxvi., part 1, July, 1913, read before the Neurological Section of the International Congress of Medicine.

[16] Journal of Experimental Medicine, vol. ix., 1907; Wollstein, ibid., 1911.

Institute, made a communication to the Neurological Section which greatly interested me and which seems to be full of promise for the future. His plan, of which he has already published a preliminary communication,[17] is to introduce the serum of one who has just received an intravenous injection of salvarsan, diluted with normal saline, into the spinal subarachnoid at intervals of from two to three weeks. In some cases the results have been very marked—the pleocytosis has disappeared, the globulin has decreased, and in some the Wassermann reaction has become negative, and there has been a general amelioration of the symptoms.

Swift and his colleague sum up their results very cautiously as follows: "While the series of cases reported is small, we feel that the results up to the present are of sufficient value to warrant a continuation of the work on a larger scale. Doubtless the best results can be obtained from the intravenous treatment with salvarsan or neo-salvarsan, combined with intraspinous injections of the patient's own serum, possibly with the addition of small amounts of neo-salvarsan. It is hoped that the treatment here outlined will be of aid in those forms of syphilis, the treatment of which has formerly been so unsatisfactory." I am sure we all cordially echo this modest hope, and if it should be realised we shall have the satisfaction of at last triumphing over the hitherto incurable group of parasyphilitic diseases which at present constitute such opprobria of our art.

THE RELIEF OF THE PAIN OF LARYNGEAL TUBERCULOSIS.

BY EDWARD D. DAVIS, F.R.C.S. ENG.,

ASSISTANT SURGEON, NOSE, THROAT, AND EAR DEPARTMENT, CHARING CROSS HOSPITAL, ETC.; LATE SURGEON-LARYNGOLOGIST, MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.

VERY few diseases cause more pain and misery than laryngeal tuberculosis, and though relief is frequently difficult to obtain any efforts to ease such unfortunate patients are amply repaid. The relief of pain is followed by marked increase in weight and a corresponding improvement in the general condition of the patient produced by the loss of dysphagia and the increased amount of sleep. The amount and distribution of pain vary considerably. In a number of cases of extensive and advanced laryngeal tuberculosis there is no pain. Lesions limited to the vocal cords are practically painless and are well known to be the most favourable form of the disease. The lesions are often multiple, and for that reason it is difficult to ascertain which one is the actual cause of the pain. The acute cases, those which run a rapid retrogressive course, are the most painful, particularly those in which there is an exacerbation of the ulceration in a more or less chronic case. The addition of sepsis is another cause of increased pain, and is one of the many facts which emphasise the extreme importance of the elimination of oral sepsis in all cases of pulmonary and laryngeal tuberculosis. The lesions which cause most pain are: firstly, the superficial ulceration of the fauces, tonsils, and pharynx, often a late and terminal stage; secondly, ulceration of the base of the tongue, an extension from the epiglottis, in which every movement of the tongue in swallowing gives severe pain; lastly, ulceration of the arytenoids, and the perichondritis which sooner or later follows, is a frequent source of pain, more particularly when the aperture of the larynx is closed during the act of swallowing.

The distribution of pain produced by a definite lesion varies. The commonest site of pain is immediately over the larynx, and frequently the patient will indicate with his finger the surface marking, so to speak, of the painful lesion. Ulceration of the fauces and deep ulceration of the ventricular bands of the larynx will produce pain in the ear; ulceration of the base of the tongue and epiglottis is referred to the root of the tongue and more rarely to the roof of the mouth. Pain in the mid-line of the neck occasionally means ulceration of the posterior commissure and arytenoids, but the distribution of the pain does not always accurately indicate the position of the painful lesions. The majority of patients complain of a tearing pain during coughing and swallowing, a few that the pain is constant, especially at night.

In order to relieve the pain the cough should be restrained, and the prevention of cough (except the useful early morning cough) is more important than the resting of the larynx by silence. The patient should be encouraged to exercise control and to restrain all unnecessary coughing. Little advance has been made in the treatment of cough, and the same more or less ineffectual remedies are tried. The continuous inhalation of creasote, eucalyptus, menthol, and chloroform with a Burney Yeo or similar respirator is usually successful. Heroin, codeia, morphia linctus, and the trochiscus ipecacuanhæ cum morphia are used, and of these last remedies the ipecac and morphia lozenge is the most useful. The cough produced by the entry of fluids and food into the larynx in the terminal stages of the disease is the most hopeless and difficult to control, and no remedy appears to be of any value. The patient is dyspnœic and too weak to hold the breath during swallowing, and this most distressing symptom really means a rapid termination. At this stage desperate measures, such as gastrostomy, are suggested as a last resource, but the condition of the patient does not allow it, and feeding by an œsophageal tube is much too painful and adds to the distress.

The dysphagia is frequently intense and leads to emaciation and almost starvation. One of the most successful methods of treating this condition was suggested by Dr. Rudolf Hoffmann, of Munich, who injected the internal laryngeal nerves with alcohol and gave these patients considerable relief. In suitable cases the immediate relief of the dysphagia is remarkable, but it depends on two essential factors. Firstly, that the painful lesion must be within the area of distribution of the internal laryngeal nerves—in other words, a lesion of the ventricular bands, the anterior surface of the arytenoids, the aryteno-epiglottidean folds, and the laryngeal surface of the epiglottis. If the lesion is at the base of the tongue, on the fauces, pharynx, or elsewhere, relief is not obtained; consequently injection of alcohol is frequently useless. Secondly, the alcohol must be injected into the nerve or the loose areolar tissue in its immediate neighbourhood. For this second reason the author made dissections of the internal laryngeal nerves and injected methylene blue into the nerves of a number of post-mortem subjects. The most accurate surface marking is midway between the hyoid bone and the upper border of the thyroid cartilage immediately above the superior thyroid tubercle, that is the name given to the prominence of the upper extremity of the oblique line of the ala of the thyroid cartilage to which the inferior constrictor is attached behind and the thyro-hyoid muscle in front. In most subjects the superior thyroid tubercle is easily palpated, and particularly so in the thin tuberculosis patient. Sometimes the nerve pursues an abnormal course. It is usually single, but occasionally it spreads into a number of branches before it pierces the thyro-hyoid membrane. Fetterolf states that the nerve may enter the larynx through a foramen in the thyroid cartilage. As it passes through the membrane the superior laryngeal artery lies immediately in front of it, but the carotid vessels are some distance away and not likely to be injured by the needle of an injecting syringe. The injection of methylene blue in post-mortem subjects tested the accuracy of the above surface marking, and in all cases the pigment was found in the loose areolar tissue surrounding the nerve and staining its sheath, but it was very doubtful whether the needle of the syringe had actually penetrated the sheath of the nerve. Within the pharynx the methylene blue could be seen in the submucous tissue about the middle of the inner wall of the pyriform fossa—that is, in the aryteno-epiglottidean fold midway between the arytenoid and epiglottis.

During a period of a few months I injected a solution of 2 grains of eucaine in 1 ounce of 80 per cent. alcohol into the internal laryngeal nerves of 12 selected cases to relieve the dysphagia. The method of injection adopted was that described by Dr. J. Dundas Grant in THE LANCET of June 25th, 1910, p. 1754, and is briefly as follows. The patient is in the prone position with the head and neck slightly extended and the chin turned away from the point of injection. To avoid sepsis the skin in the region of the nerve is painted with iodine. The larynx is pressed out of the mid-line by the thumb and made to project on the side about to be injected. The nerve is marked out by the nail

[17] Swift and Ellis, New York Medical Journal, July 13th, 1912.

of the index finger, which is placed between the hyoid bone and the thyroid cartilage and immediately above the superior thyroid tubercle where a tender spot is found. The blunt needle of Schlosser's syringe is now pushed in with a jerk at right angles to the surface and at the middle of the finger nail to a depth of 1½ cm.—i.e., to the mark on the needle. The needle is carefully moved so as to seek the spot at which the patient complains of pain in the ear. A few drops of the solution of alcohol are injected, and if there is a violent fit of coughing it indicates that the needle has possibly entered the pharynx and is too deep, but this very rarely happens. Finally, the slightly warmed alcoholic solution is injected until the pain in the ear has ceased. About 1 to 2 c.c. is generally sufficient.

Of the 12 cases mentioned above not one showed any signs of hæmorrhage, injury to the surrounding structures, or other disturbing results—in fact, the proceeding is not much more difficult than the usual hypodermic injection. With the laryngoscope the side of the larynx injected was found to be slightly paler and appeared to be less sensitive when touched with a laryngeal probe. This local anæsthesia is probably the cause of the immediate relief experienced in most cases. In two cases both nerves were injected at the same sitting without any untoward symptoms and without the regurgitation of fluid into the larynx during swallowing, but as a general rule it is wiser to allow a few days to elapse before the injection of the second nerve. Of the 12 cases 2 were unsuccessful owing to ulceration of the pharynx in one and extensive disease in the other. One patient obtained complete freedom of pain for one month and put on 3½ lb. in weight in a week. This patient died a few months later from diffuse pulmonary tuberculosis, and microscopical sections were made of the internal laryngeal nerves and compared with a section of the same nerves of a healthy subject who had been killed by an accident. The nerve which had been injected twice showed increased fibrous tissue and numerous spaces within the bundles of the nerve fibres.

Dr. Dundas Grant records 6 successful cases of the injection of alcohol for the relief of pain. Dr. G. Fetterolf, of Philadelphia, records 26 cases, and his results were: complete relief after one injection, 10 cases; complete relief after two or more injections, 6 cases; partial relief, 8 cases; no relief, 2 cases. Dr. H. Horn, of San Francisco, has published 10 cases, 7 of which were relieved by injection, the relief lasting from a few hours to 40 days. My experience confirms the fact that the duration of relief is variable and may last as long as 40 days, but there is no objection to two or even more injections. Unfortunately, the cases suitable for the injection of alcohol are limited, and frequently the disease has extended to the epiglottis and other areas.

Ulceration of the free upper portion of the epiglottis is treated by amputation with punch forceps. This is not a serious or difficult operation, and is similar to the extraction of a normal lower wisdom tooth. The wound heals rapidly within 10 days with surprisingly little pain and considerable relief of the dysphagia. A careful inquiry into cases of amputation of the epiglottis did not produce any evidence to indicate that the operation interfered with the closure of the larynx in swallowing. The chief function of the upper portion of the epiglottis is to direct the current of air into the naso-pharynx during respiration, and it has been proved that it takes no part in the closure of the larynx during deglutition, hence the fear of aspiration pneumonia does not exist. Amputation of the epiglottis is performed for the relief of pain and to prevent extension of ulceration to the base of the tongue. In addition, the removal of an œdematous epiglottis greatly facilitates inspection and any intralaryngeal operation such as cautery puncture.

Galvano-cautery puncture and curetting frequently ease pain, more especially if the area so treated is painted with tincture of iodine before and after operation to eliminate as far as possible the addition of sepsis. When it is ascertained that a particular lesion such as the upper portion of the epiglottis is the cause of pain it is well worth removal—the relief given to the patient is truly remarkable. The distressing ulceration of the fauces and base of the tongue is improved by painting the lesion with tincture of iodine and insufflating with orthoform and anæsthetin powder. In the more chronic cases relief is given by "digging out" the ulcer with a sharp Heryng curette on a straight handle, and when accessible completely excising it and closing the wound by a stitch.

The diet is worth consideration in dysphagia, and patients learn to avoid acid drinks, spiced seasoned food, and condiments. Minced soft food of the porridge consistence is more easily taken. The position known as Wolfenden's, which depends on the gulping of food, gives practically no relief. Similarly, pressure on the ears is useless, but if the larynx is pushed upwards and firmly gripped to insure as little movement as possible a slight amount of relief is obtained.

The effect of the insufflation of powders such as orthoform and anæsthetin or morphia is transitory, and depends on the skill of the patient in getting the powder well into the larynx. An examination of most cases after insufflation with Leduc's tube reveals the powder in the pharynx and very little of it in the larynx. An attempt was made to apply light treatment to the larynx, either by artificial light or sunlight, a method advocated by French laryngologists, Drs. R. Alexandri, Collet, and Labouré. Artificial light or sunlight is projected on to a laryngeal mirror placed in the pharynx, and the larynx is exposed for short periods, as in a case of lupus of the face. Œdema of the larynx is a possible occurrence, but no opinion can be expressed on the method with such limited experience as already obtained. There is considerable difficulty in the details of application, and only the most tolerant and intelligent patients are suitable.

In conclusion, though it is a well-known and proved fact that the condition of the larynx depends on the extent of the disease of the lung and is a part of the pulmonary affection, yet these unfortunate patients are deprived of considerable relief and comfort by passive and expectant treatment. When the larynx is involved a vicious circle occurs, in which the dysphagia, sleeplessness, and cough produced by the painful lesion markedly increase the rapidity of the progression of the lung condition. The judicious removal by surgical methods of painful lesions undoubtedly relieves pain, and vigorous methods with careful research are needed to attack the much-dreaded laryngeal tuberculosis.

HEREDITARY OPTIC NEURITIS:

ELEVEN CASES IN THREE GENERATIONS.

BY A. S. WORTON, M.D. GLASG., F.R.C.S. ENG.,

OPHTHALMIC SURGEON, KENSINGTON AND FULHAM GENERAL HOSPITAL; CHIEF CLINICAL ASSISTANT, ROYAL LONDON OPHTHALMIC HOSPITAL.

THIS affection, frequently known as Leber's disease and also by the synonym hereditary optic atrophy, was first clearly described by Theodore Leber in 1871. It is characterised by rapid loss of central vision, usually lasting some considerable time, and followed in a certain proportion of the cases by more or less spontaneous recovery of visual function. Both eyes are affected as a rule, either simultaneously or within a few days of each other. The loss of central vision is evidenced by a central scotoma usually absolute in character, the peripheral limits of the visual fields remaining normal in extent. Many of the cases regain full normal visual acuity after the attack, but even in these cases some deficiency of the light sense can usually be demonstrated by a comparison of the results obtained from the black and grey (Bjerrum) test types. A few cases, on the other hand, go from bad to worse, and vision may be permanently reduced to hand movements or the merest perception of light. Between these extremes a varying amount of useful vision may be regained by the sufferers, and this amount is probably influenced to some extent by the mode of life both before and during the course of the attack.

The condition is essentially one of inheritance and follows the type of a sex-limited disease in so far as males are very much more liable, transmission occurring usually through unaffected females. Nettleship, from examination of data derived from collected cases, concludes that: 1. A man with Leber's disease who has children seldom transmits it. 2. An affected female has generally, like an affected male, had both parents normal; it is rare to find that she had an affected father or an affected mother. 3. An affected female may transmit the disease to her children of either sex, but of her sons some usually escape; but although she does not

give the disease to all her sons she does give it to a larger proportion of her total issue than she would do if she only carried the disease latent. In this connexion Nettleship alludes to the difference in transmission between this condition and colour blindness, where *all* the sons of an affected female are colour blind, but rightly points out that while colour blindness is an innate physiological defect, in Leber's disease it is only the *liability* which is innate. Consanguinity takes no part in the production of the condition, and the only risk from a consanguineous marriage is where an affected male marries a cousin who herself carries the disease latent, deriving it either from her affected father or through her mother from an affected male of an earlier generation. The usual age incidence of the disease is from 15 to 25 years, although cases have been recorded as early as 5 and as late as 75 years of age. (Fig. 1.)

FIG. 1.

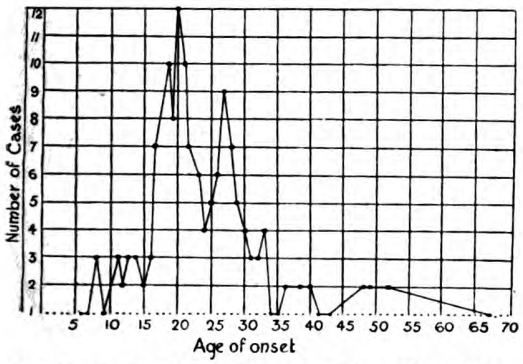

Chart to show age incidence of the disease (from 150 collected cases). Hancock: Royal London Ophthalmic Hospital Reports, vol. xvii., p. 175.

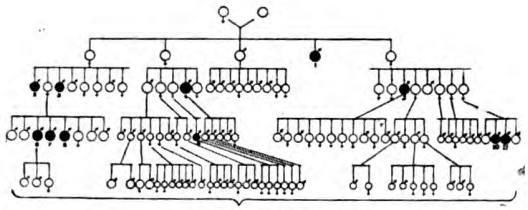
The pathology is obscure, no record of findings during the course of the attack having been made or as yet published. By some the lesion is regarded as an axial or descending neuritis set up by some toxic agency or periostitis in the neighbourhood of the optic foramen. Others, following the recent researches of Birch-Hirschfeld on the toxic amblyopias, regard it as primarily a retinal affection, and the resulting neuritis of the ascending type. Regarded from this point of view, the all-important predisposing cause of heredity would seem to imply an inherent instability of the neural elements of the retina, specially affecting the maculæ as the zones of chief activity and most highly specialised cells. It must be admitted, however, that no definite toxic agent has yet been discovered which would act as a specific exciting cause, but it would seem unnecessary to assume the existence of such, and probably any factor tending temporarily to depress the general vitality would serve in predisposed individuals to precipitate the attack. The connexion between this disease and early familial death has been pointed out, notably by Gould and Ogilvie, and with epilepsy by Hancock.

The diagnosis would depend chiefly on the discovery of similar cases in other members of the family or on tracing backwards through the female side of the genealogical tree. From retrobulbar neuritis it is distinguished by the absence of pain on pressure over the eyeball or on movements of the eyeball. Retrobulbar neuritis is frequently unilateral and runs its course towards recovery in a very much shorter time. The scotoma associated with it is also frequently relative throughout. Tobacco amblyopia is infrequent before the fourth decade of life, the scotoma is usually relative in character, and recovery, as a rule, rapidly occurs when the tobacco is stopped.



The ophthalmoscopic appearances during the attack are those simply of a mild neuritis, hyperæmia of the discs, fluffiness of the disc margins, and slight perivasculitis. The neuritis slowly subsides, and the signs of atrophy supervene, the discs becoming paler chiefly on the temporal sides. Some filling-in of the physiological cups and faint lines traceable some little distance from the disc along the vessels mark the increase of connective tissue following the inflammatory process. Some disturbance of pigment between the disc and macula has been observed in a few cases, and occasionally curious shimmering reflexes from the fundi mainly along the course of the vessels have been noted a long time after the attack. In one case (No. 10) observed by the author minute macular changes were also observed at the beginning of the disease.

The prognosis as to complete recovery of vision in a given case must be extremely guarded, but as regards retention of a useful amount of vision would appear to be good, and even in the worst cases perception of light has been retained. It is necessary to bear in mind, however, that improvement of vision rarely begins before six months from the start of the disease and has been delayed as long as three years.

With regard to treatment, it is doubtful whether the course of the disease is modified to any appreciable extent by drugs or other form of treatment. The neuritis, of course, will demand the use of dark glasses and the inhibition of all eye work. Measures directed to the maintenance of the general health, together with the avoidance of all injurious indulgences—e.g., sexual excess, alcohol, tobacco—will be required, and possibly the degree of ultimate visual recovery will be favourably influenced by small daily doses of the liquor strychninæ hydrochlor.

The symptoms and clinical course of the affection are well illustrated by the series of cases reported below (which are also shown in the family chart). Of the total number of

FIG. 2.

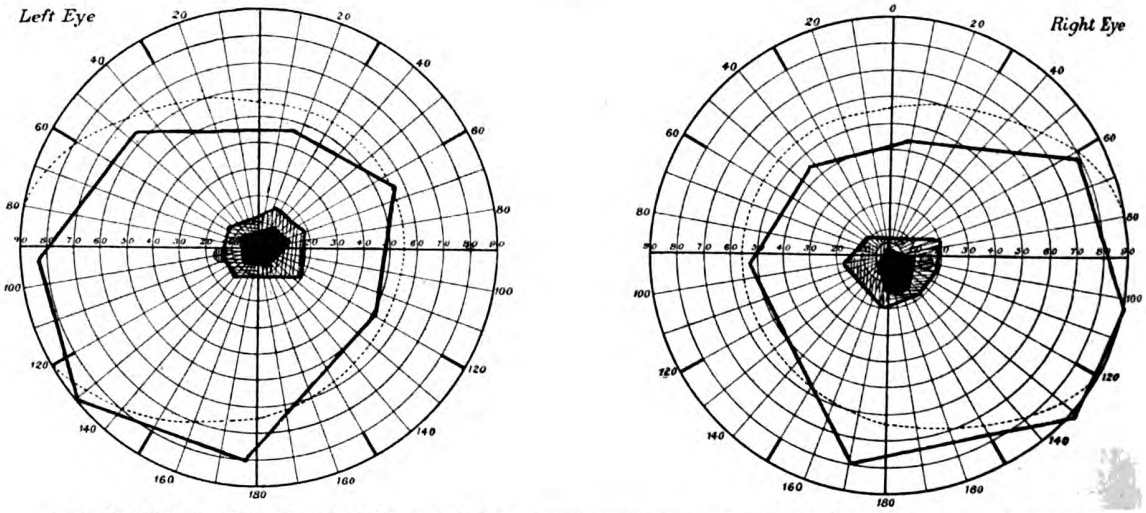
Family chart.

affected cases it has only been possible to make a detailed personal examination of four, which are given first; the information regarding the others has been obtained from relatives, and is necessarily of an incomplete and probably inaccurate character.

CASE 10.—Male, aged 19, attended Moorfields Hospital on Sept. 23rd, 1912. He complained that his sight had become very bad, and that he had been obliged to give up his occupation on this account. He stated that towards the end of May he first noticed a mistiness of his left eye, which in a few days became so pronounced that he was unable to read large type with that eye, although he observed that the vision all round the object fixed seemed quite clear. About a fortnight later the right eye became similarly affected, and his vision was so reduced that he could not trust himself to go out alone. As no improvement manifested itself he was finally advised to come to hospital.

The patient is a fairly tall, well-nourished, but somewhat sallow-looking youth. He had never been a pipe smoker, but used occasionally to indulge in a few cigarettes, which indulgence he gave up entirely when his sight became affected. He is practically an abstainer and has always enjoyed good health. His circulation, however, is poor, and he suffers much from cold hands and feet and chilblains during the colder months of the year. Nervous system normal; urine normal. There is no history of consanguinity in the parents, and no epilepsy in any member of the family. Blood pressure and coagulation were normal. He admits having masturbated before his eyes became affected, but has since that time discontinued the practice.

Vision, right and left 2/60, excentric fixation. Pupils react promptly to light and accommodation, but contraction to the former is not well maintained, the pupil after oscillation remaining in a semi-dilated condition. The visual fields were charted and revealed an absolute central scotoma surrounded by a partially scotomatous area extending to about 15° from the centre in each eye. The peripheral limits of the fields for white were normal. (See field charts.) The ophthalmoscopic appearances were simply those of a mild neuritis - slight hyperæmia of the discs, fluffy margins, and slight perivasculitis. Very fine macular changes evidenced by minute lighter areas of the choroid were also observed.



The patient when seen recently—i.e., about 15 months from the start of the disease—showed no improvement in central vision, but the ophthalmoscope now reveals the pallor of slight atrophy of the discs, chiefly on the temporal sides, the inflammatory process having now quite subsided. The treatment adopted and still persevered with is small daily doses of liq. strychninæ hyd., with attention to matters affecting the general health. Dark glasses were also prescribed.

CASE 9.—Male, aged 35. Examined personally. Affected at 14 years of age. The left eye was first attacked, the right a few days later. He first noticed that he could not see the time on a station clock when standing close beneath it. He had always had good health; not a smoker; no constipation; never masturbated. The pupils responded quickly to light and accommodation, but reaction to the former was not well maintained. Vision right and left 6/6. Bjerrum type, right, 6/9 ptly, self 6/6; Bjerrum type, left, 6/12 ptly, self 6/6. The discs on ophthalmoscopic examination were found to be somewhat pale, and the physiological cups were slightly filled in. The vessels were of

good size. The visual fields were full, no scotomata being found, but the patient occasionally confused green and blue colours in a test object of 1 millimetre square held half a metre from each eye.

CASE 7.—Male, aged 40. Examined personally. Affected at 32 years of age. The left eye was first attacked, the right a fortnight later. He found he could not read large type a few days after the eyes were attacked. Vision steadily deteriorated for two years, and now after eight years from the start of the disease is so bad that he has to be led about. About the time of the attack he used to smoke one ounce of shag weekly and was a moderate drinker. He, however, gave up these habits soon after the disease manifested itself. He had an attack of influenza one month before his eyes became affected. The patient is a healthy looking man. The pulse is slow; he suffers much from cold extremities. Since his eyes became affected he has had three attacks of suddenly falling down

FIG. 3.

CASE 10.—Fields for white. Test object 10 m.m. Showing central scotoma, surrounded by partially scotomatous area. Peripheral limits of the fields normal.

without losing consciousness at intervals of about three years. Vision right and left, hand movements. The pupils reacted well, but contraction to light was not maintained, the pupils after oscillation remaining in a semi-dilated condition. The optic discs were found to be markedly pale all over, and the physiological cups were more or less filled in. The vessels were rather small. No macular changes were observed.

CASE 11.—Male, aged 17. Examined personally. Affected at 9 years of age. The sight was bad for 12 months and then rapidly improved. The patient is a stout, ruddy, and well-nourished youth. He suffers nearly all the year round from chilblains and cold feet; otherwise he has always enjoyed very good health. He is an abstainer and only smokes a few cigarettes a week. No constipation; nervous system normal; urine normal. Vision, right and left, 6/6 nearly. Bjerrum type, right, 6/36, self 6/6; left, 6/60, self 6/6. The discs were found somewhat pale, chiefly on the temporal sides; the vessels were of good size, but faint white lines could be traced along these for some little distance from the discs. The physiological cups were slightly filled in. Marked shimmering reflexes were seen all over the fundi, but more marked over the course of the vessels. No macular changes were observed. The visual fields were taken. No definite scotomata were found, but the patient was apt to confuse blue and green colours in test objects of 1 millimetre square held half a metre from each eye. The peripheral limits were normal. The marked deficiency in the light sense was manifest to the patient himself, for he stated his inability to follow for any time a bird on the wing or aeroplane in motion against the background of the sky.

CASE 1.—Male, dead; information scrappy. Was unmarried. Age when affected not known, but supposed to be late in life. He was drowned through walking inadvertently into a pond when about 60 years of age.

CASE 2.—Male, aged 64, affected at 25 years of age. Nothing is known as to the present condition of his vision.

CASE 3.—Male, aged 62, affected at 23 years of age. Nothing is known as to present condition of vision.

CASE 4.—Male, aged 50, affected at 24 years of age. His sight is stated to be bad now, he not being able to do anything.

CASE 5.—Male, aged 56, affected at 15 years of age. His sight is said to be much better now.

CASE 6.—Male, aged 44, affected at 30 years of age. He is said to be blind now.

CASE 8.—Male, aged 30, affected at 17 years of age. He cannot follow his occupation, but can now read large type.

Summary.—All the 11 affected individuals were males. The age incidence varied from 9 to 32 years. Of the four cases personally examined two had regained practically normal vision, but leaving some deficiency in the light sense, especially in Case 11; one case (10) is still under observation; and in one (7) the vision is reduced to hand movements close to the eyes. Of the remaining six living cases nothing is known of the present visual condition of two, one is stated to be blind, and the sight of one bad, while improvement has occurred in two cases. It is noteworthy that in all the cases where visual power was completely regained or had partially recovered the age incidence of the disease was below 20 years. This would seem to have a bearing on prognosis. In conclusion, my thanks are due to Mr. M. L. Hepburn for permission to publish the notes of Case 10.

Harley-street, W.

A NOTE ON A CASE OF PELLAGRA.

BY EMMA M. JOHNSTONE, L.R.C.P. & S. EDIN., D.P.M. CAMB.,

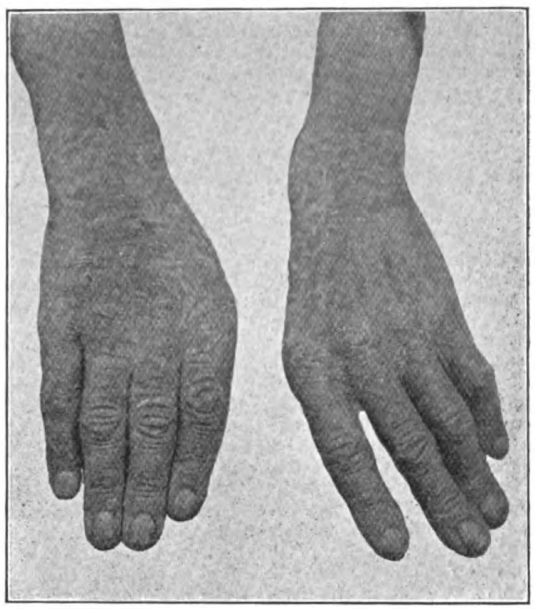
JUNIOR ASSISTANT MEDICAL OFFICER, HOLLOWAY SANATORIUM, VIRGINIA WATER.

SINCE the study of pellagra has become of practical importance to asylum physicians in this country it may be of interest to record a case occurring in this hospital and presenting many features identical with those mentioned by Dr. Gurth S. Blandy in his contribution to THE LANCET of Sept. 6th last. The dermatitis appearing after a short exposure to hot sunshine, together with the alimentary and nervous symptoms, appeared significant, and the diagnosis was confirmed by Dr. S. A. Kinnier Wilson, who saw the patient early in August.

The patient was admitted into the Holloway Sanatorium in September, 1911, suffering from melancholia with delusions. She was very thin, but presented no definite physical signs of disease, speech, gait, and reflexes being normal. She had previously been in St. Luke's Hospital from March to September, 1910, suffering from mania. During her stay at the Holloway Sanatorium her mental state varied between mild exaltation and depression. In the summer of 1912 the delusions became more marked and chiefly of an organic nature—i.e., that the abdomen was filled, bowels never opened, &c., and she protested constantly that she was too fat, though she was getting thinner. Early in 1913 she

began to refuse food and complained of abdominal pain, probably due to an enteroptosis. Her general condition became worse and she was put to bed. In April, 1913, a severe stomatitis developed, the floor of the mouth, the under surface of the tongue, and the lips being covered with flat white patches. She coughed frequently with profuse purulent expectoration, and on examining the sputum a non-Gram-staining diplococcus was found, but no tubercle bacilli. No definite signs were found in the lungs at this time, but a month later a small patch of dulness with rhonchi and moist sounds appeared in the right second space. This subsequently cleared up and the cough desisted. Meanwhile the patient had become extremely emaciated. She had incontinence of urine and fæces, and suffered much from delusions of fear and visual hallucinations. Towards the end of May she was out in the sunshine and developed characteristic skin lesions of the face and hands. A symmetrical area, sharply defined and comprising the centre of the forehead, the nose, and the lips and chin, became brownish-red, painful, and blistered. The whole of the dorsal surface of both wrists and the hands and fingers became bright red, swollen, and œdematous, with several blisters of the size of a half-crown piece, the affection also extending like a bracelet round the palmar surface of the wrist and more markedly on the radial side. Both face and hands had the appearance of being severely burnt. The swelling subsided in a few days and the patches slowly healed, but remained dark red and continued to desquamate, a process which still continues, the skin being now thickened and discoloured. The face has practically recovered its usual colour, but there is a severe seborrhœa round the nose, lips, and chin. There has also been a slight folliculitis on both legs, and during the last few weeks a small patch of dermatitis has appeared on the right elbow and the left external malleolus. Diarrhœa set in about the same time as the skin

FIG. 1.



From a photograph taken on Sept. 15th showing the general aspect and emaciation of the patient and condition of face and wrists.

lesions, and since July has been continuous. With regard to the nervous system, the gait is ataxic and stamping, the knee-jerks are unequal, but other reflexes are normal. The patient complains of burning sensations all over.

Previous history.—The patient had always been of a variable and hysterical temperament. She was born and brought up in Crookham, a village near the Basingstoke canal, and this place has continued to be her home, though she has also lived in Bristol, London, and Cardiff, in the last-named place about three years ago. She has never been abroad, has never eaten maize so far as is known, and neither during her stay at St. Luke's Hospital nor when at home were any physical symptoms observed such as are now recorded. Up to the time that mental symptoms began to appear she was well nourished. No similar cases have been found near her home, but dermatitis resembling hers occurred in two other patients here, as recorded below.

FIG. 2.

From a photograph taken on Sept. 15th of the dorsal surface of the hands and wrists.

Dr. W. Rees Thomas's letter to THE LANCET of Sept. 13th last prompts me to add that the patient has taken neither sulphonal nor trional.

The photographs were, unfortunately, not taken till the skin lesions were disappearing, but Fig. 1 shows the general aspect and the emaciation, with the edge of the affected area on the forehead and the palmar surface of the wrists. Fig. 2 shows the rough and scaly condition still persisting on the dorsal surface of the hands.

The two other cases mentioned occurred in 1912. The first was that of a woman, aged 49, a dement, who had been in the Holloway Sanatorium for 15 years. In May, 1912, the dorsal surface of her hands became severely sunburnt and blistered, desquamation subsequently taking place. At the same time diarrhœa set in, and it gradually became more severe till the death of the patient in July, 1912, the skin being still affected at that time.

The second case was that of a female patient, aged 46, who suffered from chronic excitement with delusions. She had been in the Holloway Sanatorium for two years. During the summer of 1912 her hands were severely sunburnt and blistered, large areas of skin coming away and leaving raw, painful surfaces which slowly healed. She was transferred in the autumn of 1912 to another asylum, where, I am informed, she has shown no further trouble of the kind. While at the Holloway Sanatorium she had taken sulphonal from time to time in 20-grain doses, but not for more than four days at a time, with long intervals.

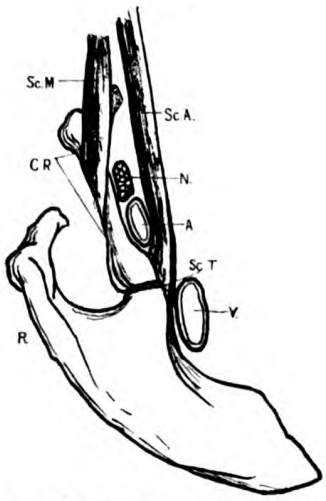
There has been no incidence of disease, accompanied by sore mouth, among the pigs belonging to the sanatorium.

In conclusion, I wish to express my thanks to Dr. W. D. Moore for permission to publish this record of cases under his care.

Holloway Sanatorium, Virginia Water.

TWO CASES OF CERVICAL RIB WITH VASCULAR SYMPTOMS.

BY E. D. TELFORD, F.R.C.S. ENG.,
ASSISTANT SURGEON, MANCHESTER ROYAL INFIRMARY.



THE symptoms associated with a cervical rib which is causing pressure are in the majority of cases nervous in type with complaint of pain and wasting of muscle. There occur, however, from time to time rarer cases in which the symptoms are vascular, and in these cases the customary nervous symptoms are slight or entirely absent.

Whilst the features of the commoner class are now fairly well known the explanation of the cases with vascular symptoms has hitherto been conjectural and unconvincing. Pressure on the subclavian artery due to the underlying rib or to action of the scaleni muscles, for long tacitly accepted as an explanation, has been shown to be without foundation. Todd, in a series of important papers on this subject, has suggested an explanation of these vascular symptoms, and I venture to report the two following cases, partly because they are those on which much of Todd's work is based, and partly because the interest of his writings has led some critics to comment on the absence of clinical and therapeutic detail from his papers. Whilst I do not feel myself competent to express any opinion on the more academic aspect of the question, I wish to place these cases on record as a contribution to the clinical side of a most difficult and interesting subject.[1]

CASE 1.—The patient, a man aged 27, was admitted to the Manchester Royal Infirmary on March 13th, 1912. He gave the following history. Twelve months before admission the patient, who is right-handed, noticed that the right index finger was numb and white. This condition gradually extended to the thumb and middle finger, and eventually by the end of the year had involved the whole of the hand. About this time he began to suffer severe neuralgic pains along the ulnar border of the forearm and hand. The limb was entirely disabled and was carried in a sling. On examination of the limb one was struck by its pallor and coldness, the whole arm resembling that of a corpse. Circulation was hardly to be perceived in the limb, and there was no pulsation in the radial, ulnar, or brachial arteries below a point one inch distal to the anterior axillary fold. The pulseless arteries could be felt as solid rounded cords. The vitality of the limb was obviously trembling in the balance and appeared to depend on the following vessels which had undergone some degree of compensatory enlargement: (1) a small artery arising from the brachial close to its commencement and running under the biceps; (2) a small subcutaneous artery running across the back of the arm midway between the deltoid insertion and the olecranon process; (3) a well-marked vessel, probably the enlarged inferior profunda artery, to be felt behind the internal condyle at the elbow; (4) a small artery palpable below and external to the dorsal radial tubercle. The pulse in the subclavian and axillary arteries was equal in volume and time to that of the unaffected left side. Beyond a slight wasting of the hypothenar eminence and some neuralgia of the ulnar side of the forearm and hand there were no symptoms of pressure on motor or sensory nerves. Tactile, temperature, and pain sensations were normal, and there were no trophic lesions. The case was one in which the vascular symptoms completely overshadowed the motor and sensory signs. At the root of the neck the subclavian artery was seen to be thrust forward and its pulsations were very obvious. Palpation showed that the artery and nerves were lying over a distinct bar of bone which proved in a radiogram to be a very well-developed cervical rib articulating with the first dorsal rib at a point about its middle. A small, less developed rib was present on the left side. There was nothing of importance in the man's previous history, and he presented no signs of syphilis.

Operation.—On the following day with the patient under chloroform an incision, three inches long, was made along the hinder border of the right sterno-mastoid, the lower end of the incision reaching to the clavicle. From this point a second incision of equal length was carried outwards along the clavicle. A triangular flap of skin with its apex at the junction of the incisions was reflected in an upward and outward direction. The external jugular vein was retracted without trouble, and the hinder edge of the sterno-mastoid and the omo-hyoid muscle were identified. The position of the subclavian artery was at once apparent, and as an exact knowledge of its condition was one of the objects of the operation it was very carefully displayed with a minimum of disturbance to the surrounding structures. It was then evident that a complete cleaning of the artery was quite without effect on its shape, size, and pulsation. The artery showed so free and tortuous a curve over the underlying rib that it was quite impossible for it to have been exposed to pressure, and free movement of the arm showed that it was not compressed in any position of the limb. The cervical rib was then cleared after retraction of the artery and lowest nerve cord and the freeing of the scaleni attachment. The rib was cut across posterior to the nerve and removed by cutting through the base of the broad process from the first rib to which it was articulated. The joint was thus removed intact and proved to be a well-formed articulation, with a synovial membrane and a strong capsule. The wound was then closed without drainage. The relationship of the parts is shown in the accompanying sketch (Fig. 1), which was made by Professor Todd at the time of operation.

FIG. 1.

Sketch showing relationship of parts in Case 1 from sketch made by Professor Todd at time of operation. SCM, Scalenus medius; SCA, Scalenus anticus; SCT, Scalene tubercle; CR, Cervical rib; R, 1st complete rib; N, Nerve; A, Artery; V, Vein.

There was some diffuse pain in the arm for a few days after the operation. This passed away, and the wound healing by first intention the patient left the hospital in ten days, at the end of which time he had lost his pain, but there was no evidence of any other material change in the limb.

Present condition (September, 1913).—The arm has made a very complete recovery. There is no pain in the limb, sensation is everywhere normal, and the appearance of the arm and the circulation in the nails are quite natural. Muscular development is good, the upper arm and forearm measuring one quarter inch more in circumference than its fellow, and the man uses the arm daily to carry bags and packages in his work. The subclavian artery retains its strongly marked arch and pulsates with unusual prominence in the neck. The pulse in the main vessel can be felt to the level of the inferior profunda artery, and there ceases, no pulse being perceptible at the front of the elbow. The inferior profunda artery can be traced down to the internal condyle of the humerus, pulsating strongly and of the size of a normal radial. The most noteworthy point in the case is that the pulse began to return, faintly at first in the radial artery, four months after the operation, and has since gradually increased in volume, until now the radial and ulnar pulsation is but slightly less than that of the left arm. In short, the examination of the arm shows that subjectively

[1] THE LANCET, May 17th, 1913, p. 1371.

and objectively it is in no way different from a normal arm save only in the lack of pulse in the lower part of the brachial artery.

CASE 2.—The patient, a woman aged 29, was admitted to the Manchester Royal Infirmary on Sept. 16th, 1912, complaining of deadness and loss of use in the right arm. She was a weaver and was right-handed. The first sign of the condition was numbness in the tips of the index and middle fingers which came on six months before admission. The index finger became very painful, and in July a large portion of its pulp became gangrenous and exfoliated. In the first week in August the whole hand became cold and numb, and by the third week of this month pulsation in front of the elbow was lost. The hand was cadaveric in appearance. The radial, ulnar, and lower part of the brachial arteries showed no pulsation and gave the feeling of solid cords. The pulse ceased at the level of the coraco-brachialis insertion, but from this point upwards the arteries were normal. No enlarged collateral vessels were found. There were no wasting or affection of muscle and no sensory symptoms whatever. Tactile, pain, and temperature sensations were normal. The patient was of spare build, and the cervical rib could be plainly felt, together with the artery pulsating strongly on both proximal and distal sides of the rib. A radiogram showed a well-developed cervical rib on both sides of the neck. There was nothing noteworthy in the previous history, and there was no evidence of syphilis.

Operation.—This was carried out on exactly the same lines as in Case 1. It was quite plain that there was no pressure on the arterial trunk. The cervical rib was of considerable size, and showed a well-marked groove on its internal border and upper surface. The shape of the rib and the extent of bone excised are shown in the sketch. (Fig. 2.) A small portion of the radial artery was removed for examination, and the condition of this vessel has been fully reported elsewhere. The wound healed by first intention, and the woman was discharged in ten days.

FIG. 2.

Reconstruction of Cervical rib in Case 2 Portion removed shown by thick lines. A, Groove for artery and nerve.

After-history.—I have seen this patient on many occasions since her discharge from hospital. The condition of the arm has steadily improved, and for the last six months she has been at her work as a weaver. She tells me (September, 1913) that she has nothing whatever to complain of and can do her full work without any trouble. She has noticed that the finger tips "feel the cold" more than those of the left hand. The muscular development and strength of the limb are normal; there are no pain and no loss of sensation. The circulation of the limb is good and the nails are pink in hue, the colour returning at once when tested by pressure. The pulse ceases at the middle of the upper arm, and neither pulse nor any enlarged collateral vessel can be found below this point. It is interesting to note that although the rib has been removed the subclavian artery is still unusually prominent in the neck and has not lost any of its prominent arch.

Manchester.

HUNTERIAN SOCIETY.—The next meeting of this society will be held (by permission of the authorities) in the Library of St. Bartholomew's Hospital at 9 P.M. on Wednesday, Oct. 22nd. The President of the society, Dr. W. J. M. Ettles, will give an address, and this will be followed by a pathological demonstration by Dr. A. S. Woodwark. All members of the profession are invited to attend. Competitors for the annual silver medal are reminded that the latest date for sending in essays for the present competition is Dec. 31st. The medal is given for the best essay by a general practitioner, embodying the results of his own observations. The competition is open to all registered general practitioners resident within Great Britain, Ireland, and the Channel Islands, whether Fellows of the society or not. Full particulars may be obtained from the honorary secretaries, Dr. O. K. Williamson, 21, Bryanston-street, W., and Mr. E. Maynard, 55, Oxford-terrace, Hyde Park, W.

THE TREATMENT OF ANKYLOSTOMIASIS.

BY R. D. KEITH, M.A., M.D. ABERD.,
PRINCIPAL OF THE STRAITS AND FEDERATED MALAY STATES MEDICAL SCHOOL, SINGAPORE.

THE treatment of ankylostomiasis as laid down in the ordinary text-books is a simple matter. Starvation and the administration of anthelmintics with purgatives are the usual means recommended, little or nothing being said as to the great difficulty, in many cases, of getting the drug to act or as to the length of time it takes to get rid of the parasites.

In the wards of the Tan Tock Seng's Hospital in Singapore numerous cases are seen in which the ova of the ankylostome occur in the fæces. A large number of these, it is true, suffer from other diseases as well, but one is convinced that Watson,[1] in a recent utterance, certainly under-estimated the importance of this condition in Malaya—at least, as far as Singapore and Johore are concerned; and in treating such cases one found that the usual methods of administering the ordinary anthelmintics were useless in all but the mildest cases, and that in anything like severe infections it was necessary to adopt more persistent and strenuous measures. In dealing with natives the great difficulty in treating this, as well as any other disease is to get the patient to stay sufficiently long in hospital to give any method an adequate trial. After a few days of rest the patients feel better and demand to be allowed to go. If they do not get permission they at once abscond, and more especially if a particularly nauseous medicine is administered. In one instance a stock mixture of thymol, bismuth carbonate, mucilage, and water was made up, the idea being that the bismuth would help to retain the thymol in the upper part of the intestine longer than would otherwise be the case. During the few days this was being employed, patients to whom it was being given were clamouring to be allowed to go, and some absconded after a few doses.

From a study of the notes of 70 cases which remained long enough in one's wards to enable one to draw conclusions as to the results of treatment, it appeared to be evident that a point of great importance is the percentage of hæmoglobin in the blood. Sahli holds that there is no *normal* for hæmoglobin in man, and that considerable variations in healthy subjects occur. There can be no doubt that such is the case, and it was therefore considered advisable to come to some conclusion as to what might be taken as a standard amongst natives in Singapore. The percentage was estimated in 28 healthy students by means of Sahli's and Dare's hæmoglobinometers, and it was found that the average obtained by Dare's instrument was 74·6 per cent., and by Sahli's 81·7 per cent. In a series of 68 patients suffering from various diseases Dare's hæmoglobinometer gave an average of 48·7 per cent., while Tallquist's scale gave 51·5 per cent. In another series of 12 patients the figures were—Sahli, 36·5 per cent.; Dare, 39·6 per cent.; Tallquist, 45 per cent. On the whole Tallquist's scale gives a higher reading than the others. In 28 cases, where the only pathological condition which could be detected was ankylostomiasis, the lowest percentage, as estimated by Sahli's instrument, was 10, and the highest was 75. The average was 40 per cent. (All the estimations were made by the writer.)

As regards treatment, one concluded that if the percentage of hæmoglobin is in the neighbourhood of 60 it may be reckoned that with suitable treatment the ova will disappear in the course of a few days. With a percentage of between 45 and 55, treatment will be more difficult. Anything below 40 per cent. will indicate that great patience will have to be exercised before recovery can take place; it will not be a question of weeks but of months, and this is certainly so when we get as low as 10–20 per cent. of hæmoglobin. Several of these cases with a very low hæmoglobin index have been under one's observation and treatment for months. It is true that the general condition improves with rest and diet. As a rule, the œdema soon disappears and the patient feels better, but the ova, though they decrease in number rather quickly at first and then more gradually, do not disappear entirely for months, while the hæmoglobin index remains persistently about its

[1] See Transactions of the Society of Tropical Medicine and Hygiene, vol. vi., No. 3, p. 92.

original level. Particulars of a few cases will serve to illustrate this point.

CASE 1.—A Chinese male about 30 years of age. On May 21st, 1912, he was admitted to hospital and up to July 24th had been given four doses of thymol and eight of eucalyptus in the usual way. On July 26th he came under the present writer's charge, and was given an emulsion containing 30 grains of thymol and 30 grains of bismuth carbonate for a dose the first thing every morning. On the 31st the ova were much reduced in number. On August 10th the thymol was stopped and a pill containing 1 grain of methylene blue was given four times daily. On the 17th a few ova were still present. On the 21st 1 ounce of an emulsion of eucalyptus oil (30 minims to an ounce) was given daily in the morning. On Sept. 14th a few ova were still seen. On this day he got a few hours' leave and did not return.

The hæmoglobin estimations gave the following results:—July 23rd: Tallquist, 30. August 8th: Tallquist, 30. August 29th: Tallquist, 35; Dare, 20. Sept. 14th: Tallquist, 30; Dare, 25. The œdema, which was very marked on admission, had completely disappeared by the time he left, but the hæmoglobin index remained unimproved.

CASE 2.—A Chinese rubber coolie about 40 years of age. He was admitted on June 16th, 1912; on the 19th ova were found. On July 3rd he came under the writer's care; thymol was given. On the 9th eucalyptus oil was given in the usual way recommended in books. On the 18th the stools still contained many ova, and still did so on the 29th. On August 12th the hæmoglobin (Tallquist) was 20 per cent. On the 17th bismuth and thymol mixture was given, an ounce every morning. After three days he absolutely refused to take any more. On the 19th the hæmoglobin was: Tallquist, 20 per cent.; Dare, 10 per cent. On the 21st one ounce of mist. eucalypti (30 minims to the ounce) was given every morning. On Sept. 2nd one ovum was seen in a field on an average; and on the 23rd one ovum in every three fields on an average. On Oct. 2nd an average of seven ova were found in a slide, and the same average was present on Oct. 10th and Nov. 14th and 21st.

On Nov. 21st the hæmoglobin remained as at the first estimation. Unfortunately, one had to go on leave for a time, and on returning the patient had gone. It will be seen, however, that though he was receiving fairly energetic treatment for several months the hæmoglobin had not improved, though the œdema had gone, and he was looking and feeling better; ova could still be found in considerable numbers

CASE 3.—A Chinese male about 40 years of age. He was in hospital for a week in the beginning of September, 1912, but absconded. At that time his hæmoglobin index was 20 per cent. according to Talquist's scale, and 10 per cent. by Dare's hæmoglobinometer. On Oct. 1st, 1912, he was readmitted suffering from anascara and grave anæmia. His hæmoglobin was 10 per cent. according to Sahli's and Dare's instruments. Numerous ankylostome ova were found in his fæces and also those of ascaris lumbricoides. There was albumin in his urine, but no casts. On Oct. 2nd mist. eucalypti (30 minims to an ounce) was given, one ounce every morning. On the 5th santonin 10 grains, followed by mist. sennæ co. On the 9th no round-worm ova were found, and ankylostome ova were much fewer. On the 17th there were about 20 ova in a slide; on the 24th about 12 ova in a slide. On the 28th the œdema was gradually decreasing. On Nov. 4th about 15 ova in a slide; eucalyptus stopped; thymol 30 grains. On the 11th thymol 30 grains; 7 ova in a slide on an average. On Jan. 20th, 1913, ankylostome ova were present; also round and whip-worm ova On the 25th santonin 5 grains. On Feb. 4th ova were still present. Hæmoglobin, Talquist, 35 per cent.; eucalyptus stopped; beta-naphthol 30 grains in powder, followed in an hour by mist. mag. sulph. every morning. On the 10th there were no ova; on the 20th two ova in a slide. On March 3rd there were no ova. On the 10th there were two ova in a slide; he was much improved and able to do light work.

The cases could be multiplied. It is by no means easy to say what the delay in getting rid of the ova from the stools is due to. It appears to be possible that, after all the worms have been killed and expelled, ova may still linger about the intestine. In this connexion the case of a Tamil may be cited. This man suffered from ankylostomiasis and was treated with eucalyptus for this, but died from another condition. Six days before his death about five ova on an average were found in a slide, while at the post-mortem examination only very few worms were found lying about the lower part of the jejunum and no "bites" were seen. There seems to be little or no ground for doubting that the usual anthelmintics kill the worms readily when they can reach them. In one case in which eucalyptus oil had been given in the form of mist. eucalypti, at a necropsy performed soon after death the intestinal contents smelt strongly of eucalyptus and the worms were found lying dead in large numbers in the lumen, though a few were still alive. It is conceivable that the ova may remain for some time in the folds of the large intestine, but they would be unlikely to do so for months. The possibility, of course, must strike everyone who has had much experience of this disease that, though there may be no fresh infection, the embryos may not have completed their circuit from the skin to the intestine at the commencement of treatment, and that fresh invasions may continue to reach the bowel by way of the trachea and œsophagus for some time afterwards.

One point having a bearing on the difficulty of treating these cases is the presence of a thick layer of mucus in the upper part of the intestine in severe cases of this disease. This indubitably must help to protect the worms against the anthelmintic. The subsequent treatment, after we have got the worms largely if not entirely expelled, is very difficult and requires great patience. Intensely fatty structures such as we find in this disease cannot be expected to return to a healthy condition quickly, and we must have patience while the fat is being absorbed and the tissues are returning to a healthy state. From recent results one has come to the conclusion that beta-naphthol in 30-grain doses the first thing every morning is likely to prove more effectual than eucalyptus or thymol. The necessity for starving patients while the treatment is being carried out is by no means evident; indeed, in bad cases it may even be harmful. More especially is it unnecessary if the drug is given the first thing in the morning. There will not be much food found in the upper part of the small intestine five or six hours after an ordinary meal, so that if the drug be given the first thing in the morning there is no necessity for starvation. It is true, that large doses given frequently of these drugs are apt to irritate the mucosæ of the stomach and intestines, but that is no reason why we should refrain from employing them in this way. Energetic treatment is needed, and I have never seen any ill-effects follow from such measures.

Singapore.

THE TREATMENT OF INFECTIONS BY MEANS OF FIXATION ABSCESSES.

BY DR. DE LOSTALOT.

MORE than thirty years years ago Fochier introduced the method of treating infections by the formation of a "fixation abscess," but it has not been very widely employed, at least in the British Isles. Those who have used it, however, consider it to be of very great value. As to its mode of action it has been suggested by M. J. Carles, of Bordeaux, that as the pus in a fixation abscess is sterile, for it contains only dead microbes, the abscess attracts micro-organisms from the blood, and that they are killed when they arrive there, though it is certain that in some cases living germs are to be found in a "fixation abscess." As the mode of action is up to the present by no means certain it is best perhaps to acknowledge that the method is really empirical, though of great value.

I am very anxious to extend more widely the use of this method of treatment, and therefore in this paper I am giving an account of the procedure and the conditions in which it is likely to be of use. Certain complications have been attributed to this method, such as pain, separation of the skin, and secondary infection of the abscess, but these when they occur are really due to the mode in which the treatment is applied and not to the method itself, for if the treatment is properly carried out they do not occur. It is of the greatest importance that time should not be lost in trying other methods before employing this; it is far better to form a "fixation abscess" and then the other methods can be used as well. The cases in which it may usefully be employed are the following: puerperal septicæmia, infectious pseudo-rheumatism, pneumonia, appendicitis, typhoid fever, and similar conditions.

The method of forming a "fixation abscess" is as follows. Two cubic centimetres of pure essence of turpentine are injected under the skin in the gluteal region. In a case of appendicitis it is important to keep as far away from the abdominal wall as possible in case an operation may become necessary later. It is hardly necessary to say that the most rigorous asepsis must be employed in making the injection. A sharp pain will follow at once, but this may be immediately relieved by the application of a hot fomentation. At the end of three days, or of four at the most, the abscess will have formed sufficiently. There is no need of a large collection of pus for the production of a phagocytosis. I have often noticed a lowering of the temperature before the formation of the abscess. A small incision, from 2 to 5 centimetres in length, should then be made to evacuate the pus, but the abscess must not be drained, and twice a day a Bier's cup should be applied. At the end of a week the abscess will be healed and the patient will be cured.

CASE 1.—This was a case of rupture of an infected extra-uterine pregnancy. The patient, 19 years old, showed signs of endometritis and salpingitis shortly after her marriage. Two months later menstruation ceased; a month later still slight menorrhagia occurred, the blood being accompanied

by sharp abdominal pains. The discharge of blood lasted three weeks, and during this time the general condition of the patient was far from good; she had slight febrile attacks; the temperature was 38° C. in the evening, with daily rigors. On vaginal examination a mass of about the size of the fist was found in the left fornix, and a diagnosis of pyosalpinx was made. The patient was kept in bed; hot douches were given, and an ice-bag was placed on the abdomen. At the end of ten days the swelling had much increased in size, and the evening temperature was 39°. The abdomen was opened, and the pelvis was found filled with clots. These were evacuated, and the left ovary and tube were removed and a drainage-tube was put in Douglas's pouch. After the operation the temperature did not improve, but increased somewhat. Three days later it was 40·5° in the evening and 39·5° in the morning; the pulse was 130, and there was diarrhœa. Examination showed that there was no accumulation of pus in the abdomen; the pus from the wound showed a large number of staphylococci and streptococci, so that evidently there was an infection of the blood. As the situation was critical I proposed to the family to make one or more fixation abscesses. Two cubic centimetres of essence of turpentine were injected under the skin of the left buttock, and by the fourth day the abscess was formed. On the same day the temperature, which was 40·7°, fell to 38·5° in the evening. On the morning of the fifth day the abscess was opened, and the pus evacuated showed an abundant leucocytosis and staphylococci. Two days after the opening of the abscess the temperature fell to 37·5° and the pulse to 100; the abdominal wound cleaned, and 12 days after the making of the fixation abscess the patient was able to get up.

CASE 2.—In this case there had been suppuration of the middle finger, and though it was incised there was lymphangitis of the arm and great enlargement of the glands in the axilla, with a temperature of 39·5° C., rigors, diarrhœa, profuse sweats, and albuminuria. At this stage the patient first came under my care. The finger was amputated, electrargol was injected, and the limb was fomented and at intervals was placed in an antiseptic bath. In spite of this treatment the fever increased, and rigors occurred with night sweats; the pulse was 130, and phlegmasia alba dolens of both lower limbs appeared. Two cubic centimetres of essence of turpentine were injected, and on the fourth day the abscess had formed; it was incised and the pus was aspirated with a Bier's cup. On the very evening of the incision the temperature fell to 38° and it did not again rise above this level. With the fall of the temperature the diarrhœa and the sweats disappeared, and it is especially interesting to note that within five days of the incision of the fixation abscess the swelling of the lower limbs disappeared, and in a fortnight of the incision the patient was able to go out.

CASE 3.—In this case the patient, a man, had an attack of typhoid fever with severe septicæmic symptoms. The diarrhœa was profuse, and there was much delirium; the temperature was 40·5° C., the pulse was 130, and pneumonia developed at the base of the right lung. On the twentieth day the left leg became much swollen, and the patient was then seen by Dr. Vaquez, who gave a very grave prognosis, saying that death would probably occur soon. On that day I injected essence of turpentine. Four days later the abscess was incised and the pus evacuated with a Bier's cup. The pus showed a great leucocytosis but no bacteria. During the following five days all the symptoms improved, the swelling of the leg diminished, and ten days after the injection it had almost disappeared. In the same time the signs of pneumonia disappeared also, and 35 days after the beginning of the disease the patient was convalescent.

In all I have had 18 cases, and since my first use of the method at Biarritz many of my *confrères* have employed it when suitable cases have presented themselves, and they have had equally satisfactory results.

I wish to lay stress on the value of the method and to urge that it deserves to be more widely known. It should be employed not merely in exceptional cases but in any case in which a patient with an infection appears to be taking a turn for the worse. It does not possess any of the dangers which have been attributed to it, it causes but little pain if given correctly, and it does not need the assistance of a surgeon.

Biarritz.

HEMIPLEGIA FOLLOWING SYPHILIS.[1]

BY MURDOCH MACKINNON, M.D. EDIN., D.P.H. OXON.,

CASUALTY PHYSICIAN TO ST. MARY'S HOSPITAL, LONDON; LATE MEDICAL SUPERINTENDENT AND REGISTRAR, SEAMEN'S HOSPITAL, GREENWICH.

Sir William Gowers has reported a case in which hemiplegia occurred three months after the primary infection, and another case is described in which hemiplegia occurred six weeks after the first appearance of the disease. It is important, therefore, for purposes of treatment, to remember that cerebral lesions may occur within the first year. Extensive lesions such as those of the case of double hemiplegia and pseudo-bulbar paralysis reported in THE LANCET of Oct. 4th are very uncommon so early in the history of the disease.

A very striking feature of this form of hemiplegia is the comparatively early age at which it appears. The great majority of cases described are under 40 years of age, and the respective ages of the four cases reported by me are 39, 30, 40, 30. At such an age it is unusual to meet with cases of atheroma or arterial degeneration, and it is therefore unlikely that hemiplegia occurring at this age would be due to intracranial hæmorrhage from arterial degeneration. Cerebral hæmorrhage, however, may result from syphilitic atheroma or from rupture of a cerebral aneurysm in a part of a vessel previously weakened by disease. These two latter conditions, however, are essentially late phenomena of the syphilitic infection, and more commonly occur after the age of 40 years. In Allbutt and Rolleston's "System of Medicine" the following appears: "Given a patient under 40 in whom there is no evidence of cardiac or renal or any other conditions likely to give rise to blocking or rupture of a vessel, we are justified, even in the absence of any confirmatory history, in assuming, for purposes of treatment at least, that the condition is the result of syphilitic arterial disease."

Multiplicity and succession of lesions are very characteristic of paralysis due to syphilis, and this is well shown in the history of three of the cases here reported. The first case, indeed, is almost unique, in that the first hemiplegia occurred within five months of the primary infection, and within two weeks' time of his recovery from this and three months from the date of onset hemiplegia as complete occurred on the opposite side. There was also motor aphasia or a condition to all intents and purposes of acute bulbar paralysis (labio-glosso-laryngeal paralysis). The patient could not protrude the tongue at all, and he was unable to swallow either solids or liquids. Memory and intelligence were retained, for he could understand quite well what was said to him, and could convey by signs or expression what he wished to say, although from the loss of power in the tongue and glottis he was unable to articulate. There was also drooping of the lower lip and constant dribbling from the mouth, all of which are consistent with paralysis from affection of the bulbar nuclei.

Cases of double hemiplegia producing those pseudo-bulbar symptoms have been described by many writers in this country, notably Sir Thomas Barlow, Hughlings Jackson, Taylor, Newton Pitt, and others. At the necropsy in Sir Thomas Barlow's case necrotic softening was found in the ascending frontal convolution on both sides. In other cases the lesion occurred in the internal capsule and lenticular nucleus on both sides, as reported by Newton Pitt. Fournier mentions a case of bulbar paralysis which occurred with right hemiplegia and aphasia. The patient presented all the symptoms of labio-glosso-laryngeal paralysis, but recovered completely under antisyphilitic treatment. Generally, however, pseudo-bulbar symptoms appear after two attacks of hemiplegia, and usually after the second attack, and this may be explained by Broadbent's hypothesis, in that bilaterally associated movements are represented on both sides of the brain. It is only when double lesions occur, therefore, that pseudo-bulbar symptoms become manifest. In Case 2

[1] This paper is an addendum to an interesting series of notes on four cases of hemiplegia following syphilis which were published in THE LANCET of Oct. 4th, p. 989. We were unable to find space for the addendum in that issue. The four cases showed that hemiplegia sometimes occurs within a few months of the primary infection, and are well supplemented by the additional matter.—ED. L.

in my previous paper six weeks previous to the onset of hemiplegia there was ptosis of the right eye. He also stated that previously thereto he had had ptosis of the left eye. Following these symptoms he had paralysis of the right side. In Case 3 in my previous paper there was ptosis of the right eye in 1907, and in January, 1908, there were sudden pain and loss of power in the right leg. In September, 1908 he had a transient attack of aphasia which lasted a few days and then cleared up.

In its appearance and mode of onset syphilitic hemiplegia may be sudden, but as a rule it comes on gradually with tingling and paresis of one or more limbs. It often occurs during sleep or when the patient is resting, the flow of blood being then slower and the conditions favourable for the formation of a thrombus in the narrowed lumen of the blood-vessels. In none of the cases mentioned was there loss of consciousness, but it may be of interest here to note that, apart from the occurrence of hemiplegia, severe headaches and epileptiform seizures occurring for the first time in a man who hitherto has been free from these are frequent accompaniments of cerebral syphilis and often precede the onset of hemiplegia.

If these cases are seen early and given appropriate anti-syphilitic treatment, there may be complete and rapid recovery. The complete disappearance of all symptoms from the multiple lesions in Case 1 was very striking. If the cases, however, are not seen early and properly treated, the result of interference with the blood-supply to the affected part of the brain is softening and irreparable damage to the nerve cells. Hence the importance in such cases of early diagnosis and treatment, and when a history of syphilis is not available, valuable information might be obtained by the Wassermann test and examination of the cerebro-spinal fluid. The interval of time elapsing between the primary infection and the appearance of the hemiplegia varied, but in three out of the four cases it occurred within nine months, the earliest being five months. In the other case syphilis was admitted, but the patient was uncertain as to the date of infection.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

Exhibition of Clinical Cases.

A MEETING of this section was held on Oct. 10th, Mr. CHARTERS J. SYMONDS, the President, being in the chair.

Dr. J. D. ROLLESTON exhibited a case showing the Value of Salvarsan in the Local Treatment of Vincent's Angina. The patient was a man aged 20, who was admitted to hospital on August 2nd, 1913, certified to be suffering from diphtheria, on the seventh day of the disease. The fauces were slightly injected. From a dirty deposit on the right tonsil numerous Vincent's organisms were obtained. Throat cultures taken on admission and on each of the two following days showed absence of diphtheria bacilli. No antitoxin was given. On August 3rd well-marked ulceration of the right tonsil was present. In spite of various local measures successively adopted—viz., application of methylene blue powder, syringing with a solution of potassium chlorate and lavender, and painting with tincture of iodine—the ulceration spread on to the palate and uvula, which became œdematous and covered with a dirty slough. There was considerable submaxillary adenitis. The throat became increasingly painful and there was some difficulty in swallowing and pain in both ears. On the 17th all other treatment was omitted and a throat swab moistened with glycerine was dipped in salvarsan powder and rubbed all over the affected area. The application was not painful, and within four hours the throat felt much easier. Subsequently three more applications of salvarsan were made. The slough entirely cleared off and the adenitis subsided. Vincent's organisms disappeared from the smear. On his discharge on the 30th only a very small opaque area was visible on the uvula, and within a week the throat became perfectly normal and has remained so since. Although the local discomfort was considerable there was no constitutional disturbance, the urine was free from albumin, and the temperature was normal throughout his stay in hospital, except on the day of admission, when it was 99° F. There was no history or evidence of syphilis, and Wassermann's reaction (August 17th) was negative.

Mr. G. H. MAKINS showed a case of Actinomycosis of the Cheek treated by Parenchymatous Injections of Formalin. The patient, a boy aged 17, was admitted into St. Thomas's Hospital in January, 1913. Two months previously an alveolar abscess had developed in connexion with some carious teeth. The abscess was incised, and shortly afterwards a hard, brawny swelling developed in the right cheek. On admission this swelling occupied an area of about the size of a half-crown piece. It was bluish-red in colour, very hard, and firmly fixed to the surface of the maxilla. Four discharging sinuses were present, and on examination of the pus exuding from these the streptothrix of actinomycosis was discovered. During the month of February iodide of potassium, beginning with 5-gr. doses, rapidly increased to 20 gr., was administered internally three times daily. On Feb. 21st two hypodermic syringefuls of 4 per cent. formalin solution were injected around the periphery of the indurated area and into the margins of the area itself. The injection was followed by considerable swelling of the cheek and lower eyelid. A second injection was made on April 4th, after which all the sinuses closed. Meanwhile considerable diminution occurred in the extent of the induration. Further injections were made on April 22nd, May 30th, and July 16th. Each injection was followed by considerable local œdema which rapidly subsided, after which the indurated tissue became less in extent and freely movable upon the maxilla. The injections were necessarily made around the circumference, since the fluid could not be freely forced into the indurated area. When exhibited the cheek was nearly normal, the only fixed spot corresponding with the cicatrix of the largest of the sinuses present when the formalin treatment was commenced.

Mr. T. H. KELLOCK showed a case of Complete Destruction of a part of the Diaphysis of the Tibia by Acute Osteomyelitis. The boy, aged 8, two years ago had a sudden acute illness associated with much pain and swelling of the left leg below the knee. An operation was performed and some bone removed. Several months later a second operation was performed. The wounds had quite healed. There was considerable mobility between the upper and lower ends of the tibia. A skiagram showed that the epiphyses were present and there was some attenuated bone leading from them, but for a considerable space there was complete absence of bone in the situation which the shaft of the tibia should occupy. The fibula appeared to be unaffected.

Mr. KELLOCK also showed a case of Osteogenesis Imperfecta with Multiple Fractures. The history of this patient was indefinite. He was an orphan boy aged 11½. He was breast-fed for nearly three months. It could not be ascertained whether any deformity was present when he was an infant. He did not walk until he was 4 years of age, and was said not to have talked until six months ago. There were five brothers and sisters, all of whom were said to be healthy. The child presented marked deformities of the long bones; the tibiæ and fibulæ were markedly bowed forwards; the femora were curved; the humeri showed marked thickening about the bicipital groove. Some of the epiphyses, especially those at the wrists, were enlarged. Skiagrams showed the long bones to be more translucent than normal and to contain comparatively little compact tissue. Spontaneous fractures were seen in the tibiæ, radii, and ulnæ, with practically no displacement of the fragments. Wassermann reaction was negative.

Dr. W. ESSEX WYNTER showed two cases of Splenic Enlargement, Hæmorrhage, Anæmia, with Oral Sepsis. The first case was that of a man, aged 50, who had severe epistaxis in May, 1913. He went to hospital and the teeth were attended to after the bleeding had been stopped. On August 10th there was sudden pain below the left ribs; the spleen was found to be enlarged, and when he was admitted to hospital on August 20th it extended to within 1½ in. of Poupart's ligament and 2 in. beyond the umbilicus in the middle line. It was firm and not then tender. The heart and lungs were normal. On Sept. 10th sudden and severe pain occurred over the spleen, with subnormal temperature, vomiting, and collapse. Friction could be heard over the organ, which was apparently the seat of an infarct. A similar

attack occurred two days later, but less severe, and no friction could be detected. On the 18th severe and persistent epistaxis occurred, which was only arrested by plugging the nostril. On Sept. 25th this recurred with less severity, both attacks being preceded by severe headache. No lesion of the mucous membrane could be detected. Blood counts showed a gradual decrease in the number of red and white cells (from 25,000), an increasing proportion of lymphocytes, and a raised colour index. The urine contained 0·3 per cent. albumin, but was otherwise normal. The teeth were much decayed, had been entirely neglected, and there was extensive pyorrhœa. In Case 2 arteritis obliterans also occurred. The patient was a woman, aged 55, who had suffered for 12 months with attacks of pain in the toes and fingers, and a month ago submitted to amputation of the left second toe for moist gangrene; about the same time the third toe on the same foot was affected with dry gangrene. Ten months ago there was slight uterine hæmorrhage. The patient continued at work as housekeeper though feeling weak and tired. On August 20th to 22nd last severe hæmorrhage from the nose and mouth occurred, the loss of blood being estimated at two pints. Previous health had been good. On admission to hospital on August 25th the skin exhibited a waxy pallor. The spleen, which was hard and not tender, could be felt 2 inches below the costal margin, and there was slight enlargement of the liver with similar characters. The abdomen was lax, and no free fluid existed in the cavity. A hæmic murmur could be heard over the præcordia, otherwise the heart and lungs showed no physical signs. Partial dentures were worn over numerous stumps, and the gums were in a very septic condition. Wassermann's reaction was negative. The blood showed anæmia with a leucocytosis of 38,400 and a lowering of the colour index.

Sir FREDERIC EVE showed a case of Angioma of the Synovial Membrane of the Elbow. The patient was a girl aged 11. One year and nine months ago the elbow became swollen and painful and she was laid up with it for a fortnight. The swelling was attributed to a blow on the part two or three years previously. Since then the elbow had become swollen every few weeks. When exhibited there was a bluish bilobed swelling on the outer side of the head of the radius; the swelling disappeared on raising the arm; after applying an elastic ligature to the upper arm it stood out prominently and the circumference of the limb at the site of the swelling was increased by ½ in. Sir Frederic Eve said that he had drawn attention to this condition in a paper in the Clinical Society's Transactions, 1903, Vol. XXXVI., p. 204, and described two cases of angioma involving only the synovial membrane, and two others implicating also the surrounding muscles. The chief interest of the condition lay in the diagnosis from localised tuberculosis of the synovial membrane. This might usually be made by observing the changes in the swelling induced by alterations of the venous circulation. Angiomata of synovial membrane often gave rise to a good deal of pain, increased by exercise. There might be tenderness, limitation of movement, wasting of muscle, and two of Sir Frederic Eve's cases complained of starting of the limb at night.

Sir FREDERIC EVE also showed a case of Bazin's Disease. The patient was a woman aged 31. The trouble began as a hard swelling on the outer side of the left leg, which broke down and discharged. An abscess formed, which gradually spread. When Sir Frederic Eve first saw her in March, 1913, there were two thin oval cicatrices on the outer side of the lower third of the left leg. At the lower and outer margin of these cicatrices was a rim composed of irregular pit-like ulcerations covered with flabby granulations. The general appearances were those of a serpiginous ulcer. There was also a very small ulcer on the inner side of the same leg. The patient appeared perfectly healthy, and a Wassermann reaction was negative. The ulcerated areas were excised and skin-grafts were applied. At the same time the affected part was exposed to the X rays. As a result of this treatment complete healing took place. Later a few pit-like ulcers reappeared, but they healed after applications of pure carbolic acid and fomentations of 1 in 5000 watery solution of biniodide of mercury, and she returned home. About three weeks subsequently the small ulcer on the inner side of the left leg broke down again, and a sore appeared on the right leg. Small areas of the margins of the scars on the outer side of the left leg also broke down. While in hospital she had been treated by X rays and had been kept in bed.

Mr. PERCIVAL P. COLE showed a case of Tumour of the Thigh in a man, aged 45, who had fractured his right femur on Feb. 10th, 1913, at the junction of the middle and lower thirds. Considerable shortening and deformity followed, but owing to the patient's cardiac condition it was deemed inadvisable to plate. He was treated on a Hodgen's splint for a few days, but pressure sores began to develop, and extension apparatus had to be abandoned. He was discharged 11 weeks after admission. An excessive amount of callus had been thrown out and union was not complete. He was readmitted on Sept. 25th. The swelling of the right thigh had gradually and painlessly increased, showing a circumference of 22½ in., as against the normal 14¾ in. The swelling was elastic and semi-fluctuating, feeling like a tense cyst. Exploratory incision was made under spinal anæsthesia, when some mucoid gelatinous fluid escaped. The tumour was composed of soft, jelly-like material, with spicules of bone embedded therein. This bled freely and surrounded the bone ends, which could just be felt. On microscopical examination it was found to be a myxo-chondroma.

Dr. ARTHUR F. HERTZ and Dr. W. JOHNSON showed a case of Bilateral Atrophy of the Face. The patient was an Italian, aged 38, who presented himself for weakness of the right side of his face, complaining that the right eye closed incompletely during sleep. His face showed a well-marked condition of atrophy on both sides, especially the left. The cheeks were extremely hollow, and the tissues covering the bones of the face were very wasted. He showed well-marked signs of chronic lead poisoning with great weakness of all the extensor muscles of the wrists and fingers of both sides. He had a blue line on his gums, and was very constipated; he had had numerous attacks of abdominal colic. He showed no other signs of disease of his nervous system; the reflexes were all normal.

Dr. H. GARDINER showed a case of Neuropathic Arthritis of the Wrist in a man aged 42. The right thumb was wounded by a splinter nine weeks ago. A good deal of pain and swelling occurred, the swelling reaching half up the arm. This quickly subsided, but left the wrist-joint swollen but painless. The right wrist was swollen and contained fluid. There was a dorsal dislocation of the wrist-joint, easily reduced. The joint was quite disorganised with osteophytic changes and rough grating. It was entirely painless and the muscular sense was diminished. Sensation of heat and cold was also absent. Tactile sensation was affected to a slight degree. There was some scoliosis which had been present for many years.

Dr. GARDINER also showed a case of Bilateral Cervical Ribs in a girl aged 17. She complained of slight weakness of both hands, noticeable chiefly when stretching big chords on the piano. The weakness had been noticed for three to four years. On examination very little abnormal could be detected in either hand, but the thenar and hypothenar eminences were not so well marked as one would have expected. X-ray examination of the neck showed the presence of bilateral cervical ribs, very well developed.

Dr. H. D. ROLLESTON and Mr. E. F. W. GRELLIER showed a case of Unilateral Clubbing of the Fingers due to an Axillary Aneurysm. It occurred in a man whose serum gave a positive Wassermann reaction. No difference in blood pressure or pulse-tracing could be demonstrated between the two radial arteries.

MEDICAL SOCIETY OF LONDON.

The Cerebro-spinal Fluid in Health and Disease.—Varieties of Facial Spasm and their Treatment.

A MEETING of this society was held on Oct. 13th, Sir DAVID FERRIER, the President, being in the chair.

The PRESIDENT delivered the opening address of the session, choosing as his subject the Cerebro-spinal Fluid in Health and Disease. The address appears in full in this issue of THE LANCET at p. 1107.

Dr. E. FARQUHAR BUZZARD read a paper on Varieties of Facial Spasm and their Treatment. He said that his object was not to deal exhaustively with every condition of disease under which facial spasm might occur, but to indicate briefly the characteristics of the chief forms which might be met with, to give them a working classification, and

to say what he had learnt about their treatment. From a pathological point of view, spasms of the face might be divided into three main classes: (1) psychogenic; (2) cortical; and (3) peripheral. This category included most cases, but there were some which it was difficult to classify with any degree of confidence. In the *psychogenic* class were the tics and the hysterical spasms. The tics had a common feature in that the movement was—in the first instance at any rate—a voluntary one. On the other hand, the true tiqueur would conceive one tic after another without effort, rhyme, or reason, and each ran riot until it died a natural or artificial death. Probably everyone was more or less a tiqueur, especially in early life, but the name was reserved for those who were not able to educate perfect control over their tendency to tic, who derived a mixture of perverted pleasure and morbid remorse from their antics, and who remained victims to this psychical disorder throughout the greater part of their existence. The habit spasms of childhood, for the most part readily amenable to treatment, must be classed with the tics, and he would also include in the same category movements which not infrequently persisted after an attack of chorea. The minor tics of childhood could generally be cured in a short time by attention to the general health and by allotting a certain amount of time every day to educating the patient's control over the movement. The true tiqueur might also yield to similar methods of treatment, but he was only too likely to develop fresh troubles of the same type in the early future. *Hysterical* facial spasm was not so common, but might be either tonic or clonic in character. In the clonic variety, where the facial movements were often associated with similar spasms in the limbs, muscular contortions were very irregular and sometimes described as hysterical chorea. Cases of hysterical tonic spasm were more rarely met with. The muscles chiefly affected were the orbicularis palpebræ, the frontalis or the corrugator supercilii. Hysterical ptosis was an example of spasm of the eyelids. He did not discuss the treatment of hysterical facial spasm in detail, but pointed out that hysterical affections of the nervous system were often extremely obstinate, and still more often tended to recur in similar or different forms. Dealing with *cortical spasm* he said that irritative lesions of the face centre in the Rolandic cortex were sometimes responsible for unilateral facial spasm. Tumours, cysts, or localised meningitis were among the possible causes. As a rule, the facial spasm was accompanied or followed by movements of the tongue or of the corresponding upper limb, but the facial muscles might be involved alone. More often the facial spasm of cortical origin was only part of a Jacksonian epileptic attack. He then considered the facial spasms of *peripheral* origin, including in this group all cases in which the seventh cranial nerve or its nucleus was the site of a lesion. Closely associated with it was the purely reflex spasm best seen in cases of trigeminal neuralgia. The contraction of the facial muscles might be brought about by an irritative lesion of the facial nerve without any painful accompaniment. He then mentioned another variety of facial spasm of chronic or even permanent duration, for which there was no obvious cause. Though sometimes called "true facial spasm" and sometimes "tic convulsif," he preferred to call it *chronic facio-spasm*, since inveterate chronicity was its chief characteristic. It was a disease of adult life affecting both sexes; the onset was insidious, the patient first noticing a slight contraction of one facial muscle. The frequency, severity, and extent of these contractions gradually increased until the patient was hardly ever free from a disfiguring contraction of all the muscles supplied by the seventh nerve of one side of the face. The appearance produced by the spasms strongly resembled that seen in patients suffering from paroxysms of neuralgia, and it was sometimes difficult to believe that they were not in pain. The patient was quite incapable of modifying the spasm by any effort of will, and any attempts to do so were usually attended by an increase of the trouble. The patients were not neuropathic, there was no local source of irritation, and their general health had been good. The only complaint that he had heard of beyond that based on the disfigurement had been a slight noise in the corresponding ear due to simultaneous contraction of the stapedius. He knew of no treatment which had any beneficial effect, and the disturbance tended to reach a certain stage of severity and then to remain more or less stationary until the end of the patient's life. Local measures were worse than useless, and sedative drugs had little influence. Alcoholic injection of the facial nerve was certainly justifiable in the case of patients who could not bear their active disfigurement with philosophy and who preferred the more passive disfigurement due to facial palsy. The results of this treatment were not always identical, and the operation was not an easy one. It was a method calculated to relieve the disorder, but not to be urged upon any patient. He could not explain the pathology of this form of facial spasm. Another variety of peripheral facial spasm went by the name of post-paralytic contracture. It was recognised by the history of the former palsy, and by the fact that the healthy side of the face at first sight appeared to be the seat of some weakness. Its treatment was very unsatisfactory. Electricity appeared to do harm, but gentle massage was occasionally helpful. He then referred to a form of facial spasm to which he gave the name fibrillo-tonic facial spasm. It was not a disease of itself, but might occur as a rare phenomenon in the course of organic nervous diseases such as cerebro-spinal syphilis and disseminated sclerosis. Its treatment, therefore, was based on the diagnosis of the primary disorder in each case. He said that he had only referred to comparatively few varieties of facial spasm, his object being to provide some help in diagnosis and treatment. The first duty of a medical man when confronted by a case was to make up his mind whether it was psychogenic, cortical, or peripheral in origin, and subsequently to distinguish between a tic, hysteria, cortical lesion, reflex irritation, post-paralytic contracture, chronic facio-spasm, and fibrillo-tonic facial spasm. The diagnosis must be based on careful investigation of every case, and, once established, the proper line of treatment was clearly indicated.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

Dilatation of the Stomach.

A MEETING of this society was held on Oct. 3rd, when Mr. A. ERNEST MAYLARD, the President, delivered an address on Dilatation of the Stomach. After referring to the development of the stomach and to its normal position and shape as ascertained by modern surgery and X ray photography, Mr Maylard said it was doubtful if there was any such condition as uncomplicated dilatation of the stomach, or if a simple chronic gastric catarrh could lead to dilatation. When dilatation was present it was much more probable that the catarrh was a consequence and not a cause, and that some obstruction existed which had indirectly given rise to the inflamed condition of the mucous membrane. The only exceptions were cases in which adhesions had interfered with efficient contraction and complete emptying of the organ. Nephroptosis sometimes acted as a mechanical cause of dilatation by kinking a portion of the duodenum or by pressing on the bowel. Diagnosis in the early stages of the disease was difficult because so many cases temporarily improved under certain forms of treatment. Thus if a patient with slight obstruction were fed with easily digestible food the stomach might overcome the obstruction and the patient be freed from symptoms of dilatation and even of gastric disturbance, but immediately he returned to an ordinary diet symptoms reappeared. Or such a patient might complain that when feeling over-tired or run down in health his gastric symptoms became augmented, and that as his general condition improved, by rest or holiday, they disappeared, only to return when he resumed his ordinary work and mode of living. In nearly all cases there followed, sooner or later, retention of the ingesta with fermentative changes. If by lavage these were prevented the motor functions of the viscus might be so improved that normal contractions would occur and all symptoms of dilatation disappear, but such would reappear as soon as lavage was desisted from. Similar temporary improvement might be secured by massage or electrical treatment. The causes of obstruction might be connected with the duodenum, the pylorus, or the body of the stomach, and might be innocent or malignant. Obstruction might be caused by kinking of the canal (the result of ptosis or adhesions), or by narrowing of the pyloric aperture

due to congenital hypertrophy or some check on the normal process of development. The latter class of case occurred mostly among young adults who, while healthy in every other respect, suffered from periods of indigestion and showed evidences of intermittent attacks of gastric dilatation. In the diagnosis of dilatation percussion alone or in conjunction with auscultation was not of much use, except in advanced cases. Two of the most striking symptoms were the quantity and character of the vomitus and the result of mechanical distension, while X ray photography had added considerably to the means of diagnosis. As to prognosis, it was almost right to say, "Once obstruction, always obstruction." Often, prior to dilatation, spasmodic contractions of the stomach caused great pain. In cases where dilatation had become permanent gastric tetany was an occasional and very fatal result. Where carcinoma was the obstructing cause death might result from one of its many complications. As to treatment, recognition of the fact that the great majority of cases of dilatation were due to obstruction would save many a patient months, and even years, of ineffectual dietetic and medicinal treatment by the timely intervention of surgery. It was a mistake to attempt to treat merely the symptom, dilatation; hence lessening the size of a big stomach by puckering or infolding (gastrorrhaphy) was seldom done now. Whatever operation was decided on must aim at overcoming the obstruction. At present gastro-jejunostomy was the method most in vogue, but cases had to be dealt with according to the nature of the obstruction; for example, by gastrolysis in case of adhesions, by fixation of the kidney in nephroptosis, by subtotal gastrectomy (if feasible) in addition to gastro-jejunostomy in carcinoma, and by Finney's modification of gastro-duodenostomy in congenital narrowness of the pyloric orifice. How successful were these methods was testified to by the excellence of both the immediate and remote results, for the mortality after operation, in experienced hands, did not exceed 2 to 3 per cent., while there could be no one who had not seen a life of perpetual gastric misery changed into one of permanent gastric joy.

At the conclusion of the address Dr. JAMES E. RIDDELL gave a lantern demonstration of skiagrams illustrating various appearances of the stomach in conditions of health and disease.

Reviews and Notices of Books.

Fibroids of the Uterus: their Pathology and Treatment. By Sir JOHN BLAND-SUTTON, F.R.C.S. Eng., Surgeon to the Middlesex Hospital. With 39 illustrations. London: Science Reviews, Limited. 1913. Pp. 240–vi. Price, cloth, 4*s.* 6*d.* net.

THE author of this monograph, who has a rightly deserved position as a leader in operative surgery, has had a very large experience in the operative treatment of fibroids of the uterus, and the views he puts forward are therefore of much interest. A perusal of this work could leave no doubt in the mind of the reader as to the serious complications which may be associated with these tumours. At the same time we must always remember that the experience of an operating gynæcologist is not necessarily such as to enable him to say what is the usual life-history of an uncomplicated fibromyoma of the uterus. A true conception of the relative danger of these tumours would be attainable if it were possible to collate the experiences of a large number of general practitioners who had had the opportunity of observing them over long periods of time and balance these experiences with the records of treatment by operation. At the present day any such opportunity is becoming increasingly unlikely to occur, because it is becoming more and more the practice to follow the general line by considering a fibroid a tumour to be removed as soon as possible. But obstetric teachers, or the majority of them, think that the dangers of fibroids in pregnancy have been much magnified by surgeons, and that the view has led to unnecessary operations being performed upon these patients with the sacrifice of unborn children. The usual course of events in a case of pregnancy complicating fibroids when the patient is not operated upon in the early months, as proved by the records of big maternity hospitals, does not form an argument for surgical interference. The opinion of many obstetricians with large special experience of these cases is that they should only be operated upon in exceptional circumstances. At the International Congress of Medicine a great deal of prominence was given to the treatment of fibroid tumours by the X rays, and, indeed, some of the German speakers talked of those who still operate upon fibroid tumours in terms of unjustifiable strength.

In discussing the interesting question of the origin of a sarcoma from a fibroid tumour the author maintains that this does not occur; in his opinion, indeed, once a sarcoma always a sarcoma. The view is maintained that the presence of fibroid tumours in the uterus is a predisposing cause of cancer of the corporeal endometrium. The presence of septic infection of the uterus is held to be an important etiological factor in the production of the menorrhagia which so frequently accompanies fibroid tumours; it is also believed to be the main factor in the production of a fibrotic uterus and in the causation of an adenomyoma of the uterus. The latter condition is termed an epithelial overgrowth, with a responsive increase of the connective tissue due to the action of micro-organisms, and therefore bearing a relation to fibrosis uteri described as an end result of septic infection. The sections dealing more particularly with surgical technique are naturally of great attraction, and if we do not agree always with Sir John Bland-Sutton, we recognise that he has enormous clinical success to reinforce his views. It is interesting to find that he practises vaginal hysterectomy with the use of clamps, that he advocates abdominal rather than vaginal drainage, and that he suggests the drawing down through the vagina with two pairs of fenestrated forceps of the bleeding edges of the vagina after total hysterectomy, so as to avoid the application of sutures or ligatures to the vaginal edges, because in his experience they are so liable to become infected and to act as setons. Here again we have a considerable difference of opinion between the surgeon and the gynæcologist. The latter would as a general rule not use clamps for vaginal hysterectomy, while practically every gynæcologist uses vaginal and not abdominal drainage, which is essentially the practice of the surgeon not accustomed to operating through the vagina.

The book contains a great deal of interesting matter and clear pathological teaching. A good many of the statements will not meet with universal acceptance; but those gynæcologists who do not agree with Sir John Bland-Sutton's views must allow that his vast experience gives him the right to hold strong opinions.

A Monograph on Albinism in Man. By KARL PEARSON, F.R.S., E. NETTLESHIP, F.R.C.S. Eng., F.R.S., and C. H. USHER, M.B., B.C. Cantab. Text Part II., Atlas Part II. London: Dulau and Co. 1913. Pp. vii. + 265–524. Price 30*s.* net.

THE second part of this monograph[1] contains a valuable collection of miscellaneous data directly or indirectly connected with albinism in man, but has not the same fascination or interest as the first. This is due to the fact, to which the authors call attention in the preface, that no attempt has been made to weld together the results of the various researches described, some of which—for example, that on the inheritance of the shape of the head and muzzle in crosses between Pekinese and Pomeranian dogs—have only a very remote bearing on the subject of the monograph.

The volume contains five chapters, of which the first

[1] The first part was reviewed in THE LANCET of April 8th, 1911, p. 942.

(Chapter VII. of the whole work) deals with the albinotic eye in man. The number of cases in which a careful microscopical examination has been made of the eye of an albino are remarkably few, but are sufficient to show that in many cases the absence of pigment is not complete. The examination of living eyes has been conducted in a far larger number of cases, but does not give such certain information as to the distribution of pigment. Such evidence as has been obtained points to the conclusion that albinism of the eye may be of many diverse kinds. The authors discuss carefully the various factors which affect the appearance of the living eye, and then go on to consider the nature and causes of the visual defects which are so common in albinos; a number of particular cases are described at some length.

Albinotic hair in man and animals forms the subject of the second chapter. With regard to it the authors maintain that the test of albinism of the hair is the absence of granular pigmentation. If this definition is accepted many persons with cream, yellow, or red hair have to be regarded as albinotic in respect to the hair, since these colours may be due entirely to "diffused" pigment. On the other hand, pigment granules may be present in "the snow white hair of the clinically complete albino." Thus there are various sorts and degrees of albinism, both of the eyes and of the hair, and they appeared to be distributed to some extent independently of one another in various members of one and the same family, which renders it difficult "to classify the members of a stock into unit categories like albinotic and not albinotic."

In the third chapter investigations of the albinotic eye among the lower animals are described, while the fourth and fifth chapters deal respectively with seasonal variation of winter-white animals and breeding experiments with albino dogs. The whole work is illustrated by an elaborate atlas of plates, many of which are admirably printed in colours.

A Text-book of Biology. By WILLIAM MARTIN SMALLWOOD, Ph.D. Harvard, Professor of Comparative Anatomy in the Liberal Arts College of Syracuse University. Illustrated with 243 engravings and 12 plates in colour and monochrome. London: Baillière, Tindall, and Cox. 1913. Pp. 285. Price 10*s.* 6*d.* net.

THIS book differs completely from what we at least in this country usually regard as a text-book of biology. It is intended for students in medical, technical, and general courses. The author goes on the principle that work in the laboratory will always precede the discussion of the text, and each chapter is written on the assumption that the student is already in possession of certain facts which he has gained from his own accurate observation. Moreover, nearly all the illustrations have been intentionally selected from material which will not be a part of the regular laboratory work, so that the student has no temptation to copy text drawings and substitute them for his laboratory observations.

The historical development of biology is first outlined, and this is taken as the natural and logical plan of study for the beginning student. Each chapter is prefaced by a very short statement of laboratory study, while the text itself explains and expands the observations supposed to have been already made in the laboratory. Movement, as one of the most obvious of animal functions, is first dealt with. The organ systems are next considered, beginning with the digestive canal of the frog, the respiratory and the urogenital organs, and the student is led to inquire as to the four-fold aspect and scope of biology: What is the organ? What does it do? How does it arise? How did it come to have its present form and relations? The physiology of digestion in the frog, circulation, respiration, and metabolism are next dealt with. This involves elementary ideas as to the nature, use, and derivatives of proteins, carbohydrates, and fats. One chapter is devoted to the histology of tissues and cells, and this is followed by an account of the nervous system of the frog. Embryology comes next with a full account of the segmentation of the ovum and subsequent processes up to the formation of the adult frog. Next comes hydra—an animal made up of tissues only. Under this head the student is introduced to the process of regeneration. Protozoa—animals made up of cells only—come next. Naturally there follows the biology of cells and the cell theory, the structure and functions of protoplasm. This leads to the study of specific movements, or as Jennings calls it, "the behaviour of animals," as studied in paramecium by what has been called by Lloyd Morgan the process of "trial and error." An exposition of mitosis brings this chapter to an end. We are then introduced to the biology of bacteria, yeasts and moulds, from a morphological and chemical point of view, and to the nature of life itself. The author now proceeds to consider classification. He deals especially with the "worm" group and insects. The economic, destructive, and beneficial work of insects is next considered and illustrated by five coloured plates and other figures.

The plant kingdom is next reviewed in a short chapter. Under the head of "Some Biological Adaptations" the question of parasitism is discussed and vividly illustrated both by pen and drawing. Symbiosis and community life are explained, and then "Biological Factors in Disease" leads to the study of rattlesnakes and their poisons, poisonous fungi, sporotrichosis, ergot fungus, galls, malaria, bacterial diseases, filterable viruses, animal tumours, disease carriers, trypanosomes, the prevention of disease, and immunity. A short chapter on some organic evidences of evolution, with portraits of Lamarck and Darwin, is followed by one on variation and heredity and the question of Mendelism. The work is brought to a close with an interesting account of animal behaviour and its relation to mind.

We have said enough to show how altogether original is the author's conception of biology; in fact, his conception is the natural one. Altogether it is a charmingly written, liberally illustrated, and singularly suggestive text-book. There are a useful glossary and an excellent index.

The Surgery of the Brain and Spinal Cord, based on Personal Experiences. By Professor FEDOR KRAUSE, Geh. Medizinalrat, Dirigierender Arzt am Augusta-Hospital zu Berlin. Vol. I., with 63 figures in the text, 24 coloured plates, and 1 half-tone plate. Translated by Professor HERMAN A. HAUBOLD. Pp 282. Price 25*s.* net. Vol. II., with 94 figures in the text, 27 coloured figures, and 4 half-tone figures. Translated by Dr. MAX THOREK. Pp. 283–819. Price 30*s.* net. Vol. III., with 42 figures in the text and 47 coloured figures. Translated by Dr. MAX THOREK. Pp. 820–1201. Price 30*s.* net. London: H. K. Lewis. 1913.

THE importance of the surgery of the brain at the present time may be gauged by the large number of careful works on this branch of surgery which have within recent years been issued from the press of this and other countries. One of the most thorough and valuable of these works is that which appeared in German from the pen of Professor Krause, and its value was in no way lessened, but rather increased, by the fact that the treatise was in the main a record of his own work and not a mere *résumé* of the work and writings of others. The appearance of the book in English will extend the sphere of its usefulness, for unfortunately all English surgeons do not read German with facility. The author does not spend space and time on discussing or describing what is well known, such as the characteristics of cerebral compression or the development of optic neuritis,

but he has devoted much space to the record of illustrative cases, with a description of the operations he has performed and the results he has obtained. The great value of the book lies in the fact that it contains the personal experience of a great surgeon, and that he gives the material on which his views are based, for he relates the cases themselves.

The translation has been very ably made, though here and there we meet with expressions which are hardly English. As an example we may quote the following: "A tumour of the cerebellum had been simulated by an enormous kyphos of the base of the skull." In the following passage the word cure seems to be misused: "Removal of a large diffuse glioma from the left frontal brain by means of suction. Cure. Three months later recurrence and death." "Recovery from the operation" would have certainly been preferable.

Illustrations have been freely used, and many of them are in colours. Some of these have been made from sketches taken at the operations.

The Diseases of Children. Edited by Dr. M. PFAUNDLER and Dr. A. SCHLOSSMANN. Translated by HENRY L. K. SHAW, M.D., and LINNÆUS LA FÉTRA, M.D. With an Introduction by L. EMMETT HOLT, M.D. Vol. I. Second edition. Pp. 499. London and Philadelphia: J. B. Lippincott Company. 1912. Price £5 5*s.* for five volumes.

THIS great work was first published in German in 1906. Some three years later it was translated into English and published in America. In 1910 a new and greatly enlarged edition was published in Germany, and now we can again congratulate Dr. Henry L. K. Shaw and Dr. Linnæus La Fétra on the completion of the vast work of translating this complete and up-to-date second edition. As Dr. Emmett Holt says in his introduction to the American edition, there is no branch of medical science which has developed more rapidly during the last two decades than pædiatrics, and its development can be measured in terms of vital statistics and the actual number of lives of children annually saved. In New York City alone there is an annual saving of 12,000 children under 5 years of age. That the development of our knowledge of the hygiene and management of childhood is very largely due to the dissemination of such knowledge through the agency of pædiatric literature and works of the kind under review there can be no possible doubt, and we in England owe a very great debt of gratitude to American enterprise that so costly an undertaking as the translation into English of Pfaundler and Schlossmann's text-book has not been left for English shoulders to bear. It is a book without which no medical library can be complete, but it is a book also with which, owing to its necessarily restricted sale, probably few publishers in this country would be willing to saddle themselves.

The German editors have made a very thorough revision for the second edition, and have added a number of new chapters—and indeed a new volume—on the surgery and orthopædics of childhood. All this new material is included in the second American edition, as well as a number of editorial notes, which from the point of view of the English reader greatly enhance the value of the book. The new matter included in the first volume covers the subjects of mortality and morbidity in infancy, and metabolism and nutrition during the first year of life. The first is written by Professor W. Prausnitz, of Gratz, and translated by Dr. Shaw, and the second by Dr. W. Camerer, of Stuttgart, and translated by Dr. Samuel Amberg, of Baltimore. As in the former editions, some 200 pages are occupied by Professor Pfaundler's systematic analysis of the symptomatology of the diseases of children—a dull, though doubtless necessary part of so complete a text-book; there is little that is new in this chapter. In the chapter on general prophylaxis, by Dr. B. Bendix, attention is paid to the prevention of infection in the new born, of postural deformities in growing children, and of tuberculosis and other wasting diseases owing to faulty methods of feeding and the neglect of hygienic precautions. The chapter on milk, by Professor Raudnitz, of Prague, translated by Dr. Shaw, indicates the vast advances that have introduced in continental methods of milk production and milk distribution. The sanitary equipment for stables and dairies, and all that pertains to milk cooling, milk filtering, and dirt estimation, may be mentioned among the many important matters that are included in this chapter, and these indicate how great has been the progress in dairy hygiene since the last edition was written. The chapter on growth and weight, by Professor Camerer, translated by Dr. Amberg, is but slightly altered from the form in which it appeared in the first edition. It still maintains its excellent character for conciseness and accuracy; the diagrams and illustrations are a feature of this chapter.

The publishers have spared no pains in regard to print, paper, illustrations, and general arrangement.

Orthopädische Chirurgie. Von Dr. GUST. ALBERT WOLLENBERG, Privat-dozent. *Leitfäden der Praktischen Medizin.* Band 8. With 147 illustrations in the text. Leipzig: Werner Klinkhardt. 1913. Pp. 264. Price, paper, 7 marks; bound, 8 marks.

Dr. Wollenberg states in his preface that this book is intended both as an initial course for medical men and as a continuation course for those who wish to study the methods of orthopædic surgery more deeply. In Germany it will no doubt be useful to those taking post-graduate courses in the subject, and forming afterwards the large body of minor specialists; but it is difficult to discover any class in this country for which such a book has any real interest. The matter is excellent, is arranged in a simple and reasonably scientific way, and the language is sufficiently brief and clear. But the treatment of the subject is too full for the English student, the methods described too German for those preparing to meet examiners. On the other hand, Dr. Wollenberg has written rather upon classical German methods than upon his own, so that the book thus loses a possible interest to the specialist. Nevertheless, it is to this latter class that the book must appeal so far as this country is concerned, and it can be confidently recommended to those who wish to read a brief but sufficient account of continental methods in orthopædics.

A Summary of London Public Health Administration. By W. McC. WANKLYN, M.R.C.S. Eng. London: Longmans, Green, and Co. 1913. Pp. 59. Price 2*s.* 6*d.* net.

THIS is a useful little handbook, of a size suitable for the pocket, which provides a list of the principal London public health authorities with a brief account of their origin; a list of those official undertakings in London which may be termed "public health services"; a list of the principal public health statutes, both general and those special to the metropolis; and a suitable index.

The metropolitan area thus considered is that of the present County of London, an area of some 117 square miles, extending about 11 miles north and south from Hampstead Heath to the Crystal Palace, and about the same distance from east to west from Hammersmith to the River Lea at Poplar. All this area, therefore, in its sanitary administration, comes under the special provisions of the Public Health (London) Act, 1891, which in various respects differ from those in force for the rest of the country. Had

"Postal London," "Police London," or "Water London" been taken as the unit, and the suburbs included, the scope of the work would have had to be so greatly enlarged that convenient presentation would hardly have been possible. The arrangement is also simplified by the omission of the small area inside the boundaries of the City of London, which in many matters is independent of the County of London administration.

The preliminary chapter gives much useful information in small space of the occasions of the formation of public bodies such as the Metropolitan Board of Works in 1855, the Metropolitan Asylums Board in 1867, the London County Council in 1888, and the Metropolitan Water Board in 1902. It also refers to the establishment of the central Government departments which exercise supervisory duties in public health matters, the Local Government Board, the Home Office, the Board of Education, and also the Board of Agriculture, an office which Mr. Wanklyn credits with public health functions. The bulk of the volume consists of a tabular statement of some 40 different "public health services," with the legislation affecting each, and the authorities which are responsible, the "services" being subdivided according as the administration principally affects (1) the normal individual from birth to death; (2) the dwelling; (3) the food-supply (4) the very poor; and (5) the sick.

Although it is stated that this little handbook has been prepared for the aid of foreign visitors to London who are interested in sanitary matters, we think it is sure to be in demand not only by sanitary officials in London, but also by the numerous members of public administrative bodies in the metropolis. We have noticed very few errors or omissions, but some reference should, we think, have been made, under the heading of "Water," to the important work of the Director of Water Examination of the Metropolitan Water Board, and the duties of the borough councils in respect of the housing and building Acts seem hardly sufficiently developed. Had space permitted, a list of the Metropolitan Asylums Board infectious diseases hospitals would have been valuable, together with a plan, however simple, of the metropolitan borough areas.

Die Physikalische Therapie der Gelenkkrankheiten für Aerzte und Studierende. Von Dr. EDUARD WEISZ, Budapest. Mit 83 Textabbildungen. Berlin und Wien: Urban und Schwarzenberg. Pp. 265. Price 6 marks.

PHYSICAL treatment plays so important a part in the management of injured or diseased joints that it is not unreasonable to devote a volume entirely to this subject; and the author of this treatise has succeeded in writing a very useful work on an important subject—a subject which is to no little extent neglected by many of the ordinary text-books on surgery. He commences by laying stress on the fact that the general condition of the patient should not be neglected if the best results are to be obtained, for affections of the joints are often merely local expressions of a general condition. The different methods of treatment are considered in turn. The various forms of splints are described; massage, curative exercises, the use of electricity, light baths, heat and cold, and sun baths, are discussed. The influence of diet is not neglected. Serum and vaccine treatment is also considered. In the second part the various lesions of joints are taken in order. For its size the book contains a wonderful amount of information on the treatment of joints.

LIBRARY TABLE.

The Bacteriology of Diphtheria. Edited by Professor G. H. F. NUTTALL and Dr. G. S. GRAHAM-SMITH. Cambridge: University Press.—This work, which was favourably reviewed in THE LANCET some five years ago, is now issued by the same publishers at the price of 15*s.* net. As we indicated upon its first appearance, it is a useful and interesting attempt to present in one volume an account of the bacteriology of diphtheria complete up to the date of publication. The nucleus of the work is the long section by Dr. Graham-Smith, while other sections are contributed by Professor F. Löffler, Dr. Arthur Newsholme, Professor F. B. Mallory, Dr. George Dean, Dr. William Park, and Dr. Charles Bolduan.

Pye's Elementary Bandaging and Surgical Dressing. Revised and partly rewritten by W. H. CLAYTON-GREENE, B.C. Cantab., F.R.C.S. Eng., and V. ZACHARY COPE, M.S. Lond., F.R.C.S. Eng. Thirteenth edition. Bristol: John Wright and Sons, Limited; London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1913. Pp. 230. Price 2*s.*—This little book, first published in 1886, is essentially a reissue for dressers and nurses of certain portions of "Pye's Surgical Handicraft." We recently reviewed the sixth edition of that work[1] as thoroughly revised and rejuvenated by Mr. Clayton-Greene, and the present work has been adapted to conform to the alterations therein, bringing it up to date. It is a useful pocket manual for dressers and nurses.

Primary Artisan Education. By W. B. WELPTON, B.Sc. London: Longmans, Green, and Co. 1913. Pp. 252. Price 3*s.* 6*d.* net.—Mr. Welpton is lecturer in education and master of method in the University of Leeds—that is to say, in a university which makes it its business to provide for a real artisan education. His book we think very good, but Mr. Welpton's ideas and advice will hardly meet with the approval of the syllabus-bound educationist. He pleads, we note, for discipline, and discipline is somewhat lacking among the younger generation of to-day except at public schools, in the services, and in such admirable organisations as the Boy Scouts. Mr. Welpton's ideal curriculum for the primary artisan school consists of culture studies, practical work, and physical exercises. These are considered generally in Chapter IV. and individually in the three following chapters, while Chapter VIII. deals with health. The book ends with an account of the Day Preparatory Trades Schools of the city of Leeds, schools which, *mutatis mutandis*, might well be imitated in other large towns. But so long as education is made a purely party question we fear that Mr. Welpton's admirable advice will fall on deaf ears.

The Nurse's Duties Before and During Operations. By E. MARGARET FOX. Pp. 110. *Treatment After Operations.* By MARY WILES. Pp. 130. London: The Scientific Press, Limited. Price 1*s.* net each.—These are two useful little books for nurses. The first is of a general character, and has much to say about the nurse's care of herself and her duties to her patients and to the medical man, and gives some general instruction in regard to her duties before and during operation, both in private and in hospital practice. The second gives detailed particulars in regard to the after treatment and duties in respect of various operations, including the special operations on the abdomen, head and ear, throat and nose, eye, vagina and rectum, plastic operations, and so forth, and considerations as to the effect thereon of age, tuberculosis, alcoholism, and other causes.

MISCELLANEOUS VOLUMES.

A NUMBER of books which, though of a medical character, are addressed to lay readers rather than to those whose professional vocation is medicine or one of its departments, may be conveniently considered together in this column. It should be noted that three of these are of American

[1] THE LANCET, May 17th, 1913, p. 1393.

origin, illustrating the fact that the direct appeal to the public is not viewed with any distrust in America.

The all-important subject of maternity comes first with three books. In *The Prospective Mother, a Handbook for Women* (London and New York: D. Appleton and Co. 1913. Pp. 343. Price 6*s.* net), Dr. J. MORRIS SLEMONS, who is associate professor of obstetrics at Johns Hopkins University, Baltimore, has written for women who have no special knowledge of medicine, and aims to answer the questions which occur to them in the course of their pregnancy. Directions for safeguarding their health are given in detail, and emphasis is placed upon such measures as may serve to prevent serious complications. The treatment of the varying conditions has not been discussed, with the idea that it should be reserved for a physician who has had the opportunity to study the individual patient. The author has endeavoured as far as possible to put what he has to say in the simplest possible language, and the result is a very interesting and useful manual. As Dr. Whitridge Williams points out in the preface he has contributed, in all branches of medicine the master word is prevention, and its benefits are nowhere more strikingly illustrated than in the practice of obstetrics. He draws attention to two points in his foreword with which we are in entire sympathy—the advance in the science of obstetrics must depend to a large extent upon the coöperation of intelligent women, and real progress in this branch of medicine can be expected to proceed only from well-equipped clinics connected with strong universities and in charge of properly trained and broad-minded men. If this excellent book of Dr. Slemons, by circulating in this country, does anything to attract the attention of English women to these two evident truths it will certainly have fulfilled an even more important mission than its author suggests for it.—*The Healthy Baby*. New York: The Macmillan Company. 1912. Pp. 235. Price 4*s.* 6*d.* Dr. ROGER H. DENNETT, instructor in diseases of children in the New York Post-graduate Medical School, clearly addresses himself to the uninformed lay public, although in so doing he carefully avoids encroaching on the rights and prerogatives of the practitioner. The advice offered throughout is for the most part thoroughly sound, but in certain respects it is perhaps regrettable that many of the instructions given are dogmatic; reasons are seldom adduced why one particular course should be followed rather than another. For instance, as regards the quantity of food which should be given to infants of different ages very clear and precise rules are laid down. The reader is not allowed to labour under the belief that two infants of the same weight and age can require quite different quantities of food. Such possibilities as acquired habits of digestion and metabolism are not considered, nor are such questions as external temperatures, degree of activity, or thicknesses of clothing—all details which must clearly modify the physiological requirements. The contents of this little volume are well arranged and easily written. The first part, consisting of some 20 pages, is devoted to development and the bodily functions. This includes details and instructions for managing the hours of sleep and the action of the bowels. In the next section nursing, hygiene, and training are considered, and we are glad to notice that the hardening process is advised, when rationally applied. In Part III. common ailments are described, but not in such a way as to equip the mother or nurse with more knowledge than it is desirable either of them should possess. In Part IV. the care of the special organs is given; in Part V. feeding and diet; and in Part VI. certain lists of nursing requirements and tables and recipes for preparing food. At the recent Conference on Infant Mortality held at the Caxton Hall there were repeated complaints that no two authorities seemed able to agree even with respect to the most important and fundamental principles of infant management; perhaps one of the most important details in infant management is connected with the regularity of the hours of feeding and the intervals between. Dr. Dennett advises a course which we believe most authorities in this country are now fairly unanimous in condemning, and that is to allow the infant to continue sleeping past its regular feeding hour; he very distinctly enjoins upon the mother not to wake the baby to feed it. We are glad, however, to note that he advises that the mouth should not be washed out for fear of damaging the naturally protective mucous membrane, and also that he warns nurses against that dangerous practice, from the point of view of infecting the genito-urinary tract in female infants, of washing the buttocks from the posterior parts towards those anterior, instead of *vice versâ*. There can be little doubt that many coli infections are caused from neglect of this precaution. Taking it all round, we regard Dr. Dennett's little book as very safe and reliable for mothers and nurses.—*Chavasse's Advice to a Mother* (London: J. and A. Churchill. 1913. Pp. 340. Price 1*s.* 6*d.* net) is too widely known and appreciated to need any description. The edition now before us (the seventeenth) has been revised by Dr. THOMAS DAVID LISTER, who has made sundry alterations from the old arrangement. Among others he has given up the question-and-answer form in which former editions were written, and has substituted paragraphs. Here and there, too, the book has been modified in accordance with modern ideas as to the occupations and amusements of girls. But in sum the book remains the same as of old, and will be found to be as useful as ever, or even more so.

Down to the close of the eighteenth century in civilised countries medicine was held to be, as it is still among primitive peoples, a mystery, something not to be revealed to the uninitiated. The tendency of modern thought, however, is to educate the layman so that he shall give the same intelligent confidence to his medical man as he does to the veterinary surgeon who looks after his horses or to the mechanic who looks after his motor-car, by teaching him enough about his body and its functions to enable him to recognise when, and to some extent why, something is wrong with it. Consequently health lectures and books on medicine and hygiene written for laymen are increasingly common. *Common Diseases*, by Dr. WOODS HUTCHINSON (London, New York, Toronto, and Melbourne: Cassell and Co., Limited. 1913. Pp. 452. Price 6*s.* net), is one of the best of its kind, though we prefer the more restrained style of Beale's "Common Ailments." Dr. Hutchinson, however, writes for Americans, whose popular literary style differs from the canons which obtain in this country. But if the manner sometimes jars the matter is excellent, and that after all is the great point. The chapters on catarrh, on the care of the feet, on insomnia, on dyspepsia, and on worry are worth every layman's reading, and although Dr. Hutchinson points out the uselessness of many drugs, he by no means omits to urge the necessity for skilled attendance and the dangers of home treatment in possibly deferring such attendance to a dangerously remote period. A study of Dr. Hutchinson's book ought to have the effect of making the layman understand when he does *not* know, and this is the object at which the medical profession should aim.

A MEDICAL MAN'S GIFT TO THE PRESTON GRAMMAR SCHOOL.—Dr. R. C. Brown, of Preston, who has made many important gifts to his native town, including an X ray equipment to the Preston Infirmary, has now presented the Preston Grammar School, of which he was a pupil, with a fine organ.

THE LANCET.

LONDON: SATURDAY, OCTOBER 18, 1913.

A Royal Commission on Syphilis.

IF the severity of a disease with its complications and sequelæ and the number of persons afflicted are to be a measure of its importance in a community there is none which can compare in importance with syphilis. It varies greatly, indeed, in the severity of its attack, but unluckily an attack of syphilis rarely ends with what is usually regarded as the disease itself. After the primary sore has healed, after the eruptions have disappeared, then in the absence of efficient treatment worse remains behind. The tertiary manifestations may be of an intensity utterly out of proportion to the quality of the earlier signs; destructive processes of a wonderful severity may show themselves, and their effects must be seen to be believed. Yet that is not all. The later expressions of the disease are in their way as formidable as those seen at an earlier stage. Locomotor ataxy and general paralysis of the insane are only two of the forms of the late effects of the disease on the nervous system; and can we feel justified in thinking that we have even now arrived at an appreciation of the whole of the results of this dire disease? It is only within recent years that we have succeeded in proving the syphilitic origin of many of the sequelæ of syphilis, and in all probability there are many other forms of disease which owe their origin to syphilis, though this connexion has not yet been made manifest. The number of those killed by the disease cannot be gathered from the returns of the Registrar-General. In the first place, there is a very natural hesitation on the part of a medical man to insert in a death certificate the fact that the cause of death is syphilis, especially as the certificate has to be handed to the relatives of the patient, so that without a real sacrifice to truth the results of the disease are inserted as the cause of death rather than the disease itself; and, in the second place, some of the manifestations, such as tabes, are so much diseases in themselves that there is ground for entering them as the cause of death rather than to go back to the original cause. So that we can have no doubt that many more deaths are due to syphilis than might be imagined from the death certificates. Great though the number of deaths due to syphilis may be, it cannot be compared with the number of cases in which suffering and illness result from this plague, and yet death does not ensue. In fact, when we consider the large number who die directly or indirectly from syphilis, the myriads who suffer in other ways from its effects, the hecatombs of infants who never see the light from this cause, and the still greater number who are born only to die in a few weeks or months, we cannot deny that there is no other malady under the sun which entails so much harm to the human race. And yet what in this country is done to mitigate its effects? The answer is—almost nothing. We spend huge sums every year in endeavouring to prevent the spread of scarlet fever; we make numerous laws to limit, and if possible to abolish from our midst, such diseases as enteric fever; we take elaborate precautions to prevent affections such as ringworm, which never can lead to the loss of a single life; and yet we do nothing officially to prevent the spread of the most virulent, the most widespread, the most persisting of all the ills to which flesh is heir. Everyone knows why. Syphilis is often the result of illicit sexual connexion, and this is the excuse—perhaps we may say the reason—for this unreasonable attitude. But it is known that a real proportion of cases of syphilis have acquired the disease in perfectly innocent ways, and it must be acknowledged by all that the old idea that venereal disease was a punishment for sin has no foundation in fact.

At last we have promise of legislation to remedy a grievous state of affairs, after an inquiry by a Royal Commission. The members of the public are beginning to recognise both the extent of the disease and the need for the adoption of some methods of prevention. As to what can be done to prevent the spread of the disease there are many opinions. At one time it was thought that the majority of the cases of syphilis came from infection from professional prostitutes, and that the methods of examination and segregation which were adopted in many countries should do much to limit the number of cases of the disease; but nearly all those who have had experience of the working of these preventive measures agree that they have on the whole failed. Now only those support this policy as have the consistency to demand the making of regulations much more severe than they are anywhere at present; and in this and other countries what may be called the moral objection to such stringency must prevent its employment to any more than a very slight extent. Besides, it has come to be recognised that in a very large proportion of cases of the disease infection comes, not from habitual prostitution, but from casual illicit intercourse, and this has not been at all affected by the rules usually employed for the control of syphilis. The Royal Commission, whose appointment may at any moment be announced, will take evidence on all matters bearing on prevention, and will in particular consider two methods by which much may be done if they are judiciously employed. The first is the compulsory notification of syphilis, but this notification must be effected in such a way as not to deter patients from seeking medical advice. The experience of those countries where a special form of notification has been adopted, without making public the identity of the patient, shows that this system has worked well; time will tell us the best means of carrying out the method, but some form of it will probably be found to give good results. The second method is to make easy and simple the treatment of syphilis. The more easy it is for patients to obtain medical treatment the more readily will they resort to it, and the diminution of the extent of the disease will before long be manifest. The introduction of salvarsan has done much to simplify the treatment of syphilis, and in it we find a notable adjuvant in dealing with this disease. All institutions which

treat syphilis should be supported and encouraged by the Government, and, while everyone now recognises this, it is tragic to remember that only a few years ago the small Government contribution to the lock hospitals was withdrawn.

Surely if ever there were a matter that deserved to be made the subject of inquiry by a Royal Commission it is the prevention and remedy of syphilis, which reckons its victims by hundreds of thousands and seriously affects the vital statistics of all nations. The direction which the inquiry takes will develop itself as it proceeds, and we believe that the true aim of the Commission will be kept in view. The majority of the members of the Commission may not be members of the medical profession, but so long as the profession is adequately represented thereon scientific purposes will be well served. An enormous social problem must be tackled by representatives of society at large. It is to be hoped that the report of the Commission will not be too long delayed. The matter is pressing, and if chances of early legislation are not taken we know from experience that long delays may follow. A reform put off once or twice tends to be indefinitely shelved.

The Unequal Distribution of Medical Practitioners.

WE are all of us accustomed to the statement that the medical profession is overcrowded. Direct contradiction of the statement made in the sessions of the General Medical Council, which is responsible for the official roll of our body, has never corrected the error in popular opinion; the obvious difficulty which many institutions find in procuring medical officers has never prevented its repetition. Yet one of the most prominent factors in the conditions that paved the way for the National Insurance Act was the deficiency of a supply of medical men adequate as to both number and locality for attendance on the working classes. The initial difficulty to be overcome seemed to lie in the uneven distribution of medical men. It was supposed that pecuniary considerations alone determined this uneven distribution, so that if a better pecuniary return to the practitioner in the poorer industrial districts could be ensured these would rapidly be supplied with good-class medical men, and this is a view of the case that has been put forward in THE LANCET on more than one occasion.

The facts upon which that belief was founded and the belief itself have now been set forth in an article by Mr. C. A. PARKER on "The Panel Doctor and the Insurance Act,"[1] in which is given a table showing the distribution of doctors in relation to population and to the health-rate in three different classes of localities: (1) residential places, such as Hampstead, Oxford, Hastings, Ealing, Eastbourne, and Wimbledon; (2) working-class places, such as Walsall, Dudley, West Bromwich, Bermondsey, Merthyr Tydvil, and Stoke-on-Trent; and (3) mixed places, such as York, Birkenhead, Reading, Portsmouth, Birmingham, and Devonport. From this table we learn that the ratio of doctors to population in the residential places varies from 1 to 476 in Ealing to 1 to 995 in Wimbledon, the mean being 1 to 657; in the working-class places from 1 to 2096 in Walsall to 1 to 8790 in Stoke-on-Trent, the mean being 1 to 4581; while in the mixed places it lies midway, as one would naturally expect—viz., from 1 to 1217 in York to 1 to 2770 in Devonport, the mean being 1 to 1967. Mr. PARKER considers that these anomalies in the distribution of medical practitioners have their origin in the existing system of competition coupled with the acceptance of payment for each individual visit. In such circumstances he would expect practitioners to flock to districts where the patients can afford to pay good fees, and to avoid the working class districts where the fees are necessarily far more modest. He uses this deduction as an argument in favour of a State medical service, since he is a protagonist in the movement for the establishment of such a system. Under a State medical service he conjectures "the salaries paid to medical men in Bermondsey or Stoke-on-Trent must certainly be as good as those paid in Hampstead and Eltham, and possibly better, for the work cannot be quite as congenial." A fallacy in this argument lies in the fact that it is the uncongeniality, not of the work, but of the conditions of living, that makes the average medical man prefer Hampstead or Eltham to Bermondsey or Stoke-on-Trent, or at any rate to the industrial localities thereof. The general practitioner, in the nature of things, is compelled to make his home in the locality in which he practises, and the industrial locality often provides him with neither domestic accommodation nor social surroundings suited to his tastes. The raising of fees in uncongenial quarters would have to be large indeed before any inrush of practitioners would be ensured. The practitioner would, as a rule, rather practise on £500 or £600 a year in a residential district, or a mixed district, where he can find a suitable home circle for himself, his wife, and family, than in a place where he can find none of these things, even though he should be able to earn more than double the amount of money. There are some of the finest exponents of medicine who do not care for social amenities (though few, we imagine, among them are married); and an admirable missionary spirit leads other men of learning and culture to devote their life to medical work in slums, but these must ever be largely in the minority. It is not that the work is so uncongenial; in the actual rendering of their professional services to suffering humanity we believe that the vast majority of medical men are no respecters of persons, that to them suffering is suffering, and equally demands relief whether the sufferer be peer or peasant, plutocrat or pauper. But it is that in their periods of leisure they are deprived of the possibilities of congenial companionship and social amenities, that their lives and those of their wives and children are passed in exile from their own kind when they elect to practise in wholly industrial neighbourhoods.

Few there are who will willingly choose an uncongenial environment when a congenial one lies open to them. Let the mill-owner, the industrial employer, who wonders why there is difficulty in persuading a medical man to take up practice among the families of his employees who live herded together in unlovely streets, ask himself why he does

[1] The Medical World, Sept. 18th, 1913.

not live there, but prefers to reside in a distant suburb among congenial friends and surroundings. He goes to his work at his factory, but returns when it is over to an environment of comfort and, if we may believe some contemporary writers, of considerable culture. The general practitioner can look for no such things beyond what the area in which his practice lies can afford him. The root of the medical problem, as far as the distribution of practitioners is concerned, lies embedded in the concentration of industrialism. An equitable distribution of medical men to population must depend either on an equitable distribution of different classes of the population or on a much greater diversity in the social, educational, and intellectual characteristics among medical men than at present obtains, or than any true medical reformer would like to see. No adjustment of fees will remove the difficulty.

Science and the Land.

JUST about a century ago there were born two men who did, as it proved, an infinite service to their country by developing the resources of science in connexion with its applications to the cultivation of the land. Sir JOHN LAWES and Sir HENRY GILBERT laid the foundations of agricultural science in this country when they instituted the famous laboratory at Rothamsted in which they carried out their researches, now everywhere regarded as classical. This work was a remarkable effort and yielded results of the utmost importance, not only to this country, but to systematic agriculture all over the world. Previous to this work there had been no scientific attention given to this subject. We possessed little, if any, specific knowledge of the functions of the soil, air, rain, and light concerned in the great vital processes of plant growth. The needs of the plant had not attracted anything approaching scientific study, and little regard had been paid to those constituents of the soil which may promote healthy developments towards any particular usage. The only system practised which could claim some application of scientific principles was that known as the rotation of crops. The work, so well begun by Sir JOHN LAWES and Sir HENRY GILBERT, of applying the teachings of biochemistry to land cultivation has led to wonderful developments which have had a remunerative bearing upon the adequacy of the food-supply of the world. In the old laboratory at Rothamsted were laid the foundations of a new science which has helped materially towards the solution of one of the greatest of economic problems. Investigations were so diligently and successfully pursued that new discoveries in regard to plant life were established, and the value of bacteriology in this connexion was soon recognised, high functions being awarded to the organisms of the soil. Knowledge rapidly accrued on these and other points, and facts were brought to light which revealed that the healthy conditions of the soil and of the plant depended to some extent upon the activity of different biological entities.

For some time it has been known that there is in the soil a struggle for existence amongst micro-organisms just as there is in the animal kingdom. The important fact was subsequently established that the fertility of the soil can be very greatly increased by certain antiseptic applications or by treatment at a definite temperature. When certain soils were raised to a temperature of 100° C. for two hours they yielded twice as great a crop as the same soil untreated, when the two were afterwards cultivated in pots at Rothamsted under similar conditions. In the same way, when the soil was treated with the vapour of volatile antiseptics—chloroform, for example—an increased growing power of 30 per cent. was gained. It was subsequently proved that this process did not effect complete sterilisation; protozoa and amœbæ were destroyed, but many bacteria survived, and in the soil the former subsist largely on the latter. The fertility of the soil depends upon the number of its ammonia-producing bacteria, and it follows that when these bacteria lose their destroyers they are left free to carry on the work of fertilisation by elaborating ammonia. It is further probable that part, at all events, of the beneficial work of the sun is to produce a similar result, for by aiding the lives of the fertilising bacteria in killing their destroyers the soil is enriched by the increased activities of these micro-agencies. There has thus been brought to light a pathology of the soil which is deeply concerned in the question of productive power. LAWES and GILBERT initiated a great movement which had for its starting point an inquiry into the chemistry of arable soil and the plant. As, however, the work of exploration proceeded the investigators soon found themselves face to face with biological considerations. It was, for example, for a long time an open question as to what was the rationale of the process by which the nitrogen of the air was directly assimilated by certain plants, notably by the leguminosæ. It was later shown to be due to the work of micro-organisms which were found in large numbers on the root nodules. The future of scientific agriculture must largely rest upon the success which attends the joint operations of the biologist and chemist—in fact, the same lesson is being learned in the field which is being taught in the modern hospital. The bio-chemist is in constant requisition in all paths of investigation, and it is largely to the work of LAWES and GILBERT that we owe the rapid development which has taken place in bio-chemistry, adding considerably to our knowledge of the laws of nutrition, not only in regard to plant life, but to animal life also.

The discovery, moreover, of a process by which great native deposits of rock phosphate are rendered into soluble phosphoric acid available for plant nutrition has been the foundation of an enormous manufacturing industry. The work at Rothamsted still goes on, and it is entrusted to capable and competent hands. Students of all branches of science, in view of the cosmopolitan relations of this work, would deplore, we feel sure, any signs of its abatement taking place for mere lack of financial support. An excellent opportunity has come for making the continuation of these brilliant researches possible and effective. The year 1914 is the centenary of the birth of Sir JOHN LAWES and 1917 that of Sir HENRY GILBERT, and it is proposed to collect the sum of £12,000 to erect a suitable commemoration laboratory at the Rothamsted experimental station, where additional accommodation is badly needed. It is understood that if half of this sum

is raised by public subscription the other half can be obtained as a grant from a development fund. This leaves a sum of £6000 which the public is asked to subscribe, a moderate sum surely for so worthy an object. There should be no doubt about the response when the excellent record and traditions of the Rothamsted Laboratory are taken into account. Whoever has the land, and whatever changes in its tenure any political party devises, the fertility of the soil must count, and Rothamsted has shown us how to promote this fertility.

Annotations.

"Ne quid nimis."

THE LONDON COUNTY COUNCIL AND THE REGISTRATION OF NURSING HOMES.

FOR many years suggestions have been periodically put forward for different degrees of supervision by local authorities over the various enterprises which are included within the somewhat elastic and undefined terms, nursing home, private hospital, therapeutic institute, massage establishment, and the like. Hitherto nothing, with a minor exception to be noted presently, has been accomplished in this direction; and these commercial enterprises are carried on without hindrance from the State or any other body politic. Whether this communal indifference to private therapeutic establishments is economically sound or not is a large question, with much to be said on both sides. There are, however, certain aspects of it which scarcely admit of much dispute; and in view of changes in the prevailing practice in London, for which the London County Council is said to be seeking Parliamentary sanction, the conditions which are probably held to constitute justification for a new procedure become interesting to medical men. Nursing homes and private hospitals of the genuine kind have increased enormously in number during recent years, and it may be taken for granted that the reason is because they fill a public want. Admirably as a great many of these homes are conducted by those (almost always women) who manage them, it must be admitted that the standard varies very widely indeed. In the West-end of London the severity of competition has tended towards an ever-rising level of efficiency; only those proprietors who keep their homes thoroughly equipped and staffed can obtain constant patronage. But even here there are degrees of excellence, and a badly conducted home may contrive to live for a time on a reputation gained in former days. Elsewhere in London, in the suburbs, and in the provinces the proportion of indifferent homes is higher. One of the principal reasons for this is no doubt a financial one; the fees which the public will pay are often not large enough to enable the proprietors both to make a living and to provide first-class service. A recent inquest has served to show, what has long been known, that the nursing in some nursing homes is entrusted to untrained, or very partially trained, women. If the foregoing statements are accepted, there is a *primâ facie* case to be made out in favour of some sort of control, inasmuch as life and death may hinge on the care which is bestowed upon the patient. Whether the disadvantages of such control are held to outweigh the advantages or not, at least it is certain that only an expert medical man is competent to carry out, possibly with the assistance of a very experienced nurse, the necessary inspection. Supervision of medical and surgical equipment or treatment, or of nursing, or of discipline and administration, by a non-medical inspector would be quite useless. There are, however, institutions in existence which stand in need of supervision more urgently than the genuine nursing home. There are, to begin with, numerous establishments on a commercial basis which provide, or affect to provide, for sufferers from a great variety of diseases treatment by electricity, light, heat, baths, massage, and even by radium. Some of these are conducted by medical men and are as genuine as the best type of nursing home; but some of them are in the hands of unqualified laymen, a proportion of whom appear to us as fairly unscrupulous persons. Here, too, inspection would have to be entrusted to medical men, if it were to determine the genuineness of the treatment carried out. Again, all these therapeutic or semi-therapeutic organisations are liable to be used as a cloak for vice; and, unfortunately for honestly conducted places, a sinister reputation in this respect attaches to establishments for massage, electricity, and baths, though nursing homes have also had to suffer the same sort of reflected discredit. The suppression of brothels masquerading under semi-medical guises is wholly distinct from the supervision of respectable places for treatment, and is an affair for the police, not for a medical inspector. It will be evident, then, that any policy of inspection and registration devised for these various kinds of establishment should be carefully thought out and fully discussed, for the question bristles with difficulties which we have only attempted to suggest. If, in the result, methods of inquisition should be adopted, the detailed mechanism should receive careful attention; there should be nothing inconsistent or haphazard, and any system should, in its outlines, be national, not local. London may lead the way, but it should not remain alone. Unfortunately, there are indications that these points are being neglected. For one thing, there has been no (recent) discussion or ventilation of the subject worthy of the name. For another, local authorities are inclined to action which is neither preconcerted nor coördinated. And, worst of all, there is an attempt to deal with the problem piecemeal by administrative action. Thus the London County Council intends next year to seek powers to register and inspect maternity homes and massage and electrical establishments, with the object of assisting the police in the suppression of disorderly houses. This proposal would entail the registration and inspection of practically every nursing home, since massage and electricity are frequently ordered for patients by practitioners, and not a few women now enter nursing homes for their confinements. It is, therefore, important that this result should be realised, and that it should be made plain that, whereas the disorderly house can most fitly be inspected by policemen or municipal officers, the supervision of genuine nursing homes and institutes cannot usefully be conducted by the same machinery. This danger of the extension of by-laws, desirable in themselves, so as to cover cases not originally contemplated and better dealt with in other ways, is well illustrated by the history of the Employment Agency Regulations. About three years ago the London County Council obtained power to register employment agencies, whereupon all nursing homes were called upon either to register or to refrain from sending out, or calling in, any nurse not on the staff for any case however urgent. This surreptitious method of dealing with the registration of nursing homes and allied businesses is highly to be deprecated. By all means, if after full discussion the representatives of the people approve it, let a thorough system of control and inspection be created. Pending such a decision and such a system, it would be preferable to avoid the inclusion of attempts to raise the level of technical

efficiency of respectable institutions in schemes for the suppression of disorderly resorts. To distinguish between immoral houses and nursing homes is a totally different thing from the assessment of relative degrees of merit among the latter. Hastily considered plans for the first may involve unsatisfactory arrangements for the second, unless it is clearly apprehended from the outset that the two questions are entirely different.

CINEMATOGRAPHS ON PRIVATE PREMISES.

THE National Hospital for the Paralysed and Epileptic, summoned in the person of its secretary, has been compelled to pay in fines and costs the sum of £8 3*s*. for a contravention of the regulations made by the Secretary of State under the Cinematograph Act, 1909. The penalty appears to us to be somewhat in excess of the needs of the occasion, for although those responsible for what was apparently a breach of the law were aware of the nature of the regulations under which public cinematograph exhibitions are held, they were evidently of the opinion that the circumstances in which they were demonstrating with inflammable films were not illegal. The occasion was a lecture delivered to members of the Section of Neuropathology of the International Congress of Medicine, when Dr. Weissenberg, of Philadelphia, demonstrated the value of certain films for educational purposes. The demonstration took place in the lecture-theatre of the medical school, provided with three exits; the hospital fire brigade was present, buckets of sand and wet blankets were at hand, and the films were in a fireproof box, with a safety shutter which closed automatically if a film stopped running. The breaches of the regulations consisted in not indicating the exits which existed, and in not enclosing the apparatus in the prescribed manner. It was contended, on behalf of the hospital, that the lecture-theatre came under Section 7, Subsection 4, of the Act, which says that the statute in question "shall not apply to an exhibition given in a private dwelling-house to which the public are not admitted whether on payment or otherwise." No doubt those who were responsible for the use of the building in question considered that they were exempt from compliance with regulations framed for public exhibitions, in that they were arranging for a lecture to take place in a private building and before an audience of medical men specially invited. An officer of the London County Council had expressed himself satisfied on a previous inspection of the theatre. It would not be right to protest in any way against the strict enforcement of the law, but the authorities of the hospital took every possible precaution. We call attention to the case because the use of cinematograph films to illustrate lectures is likely to increase, and in order that lecturers may be warned as to the restrictions imposed. The Act is not unreasonable in the conditions which it lays down as to places where films may be exhibited, and makes special provision for premises used occasionally and exceptionally for such a purpose.

BAKING POWDER.

Professor E. F. Ladd, Commissioner of Food and Drugs for the State of North Dakota, has recently made a number of observations regarding baking powder, with the object of fixing the standards of purity, quality, and strength. It is directed that the label shall show the net weight and be free from advertising or descriptive matter. Baking powders containing 1 part per 1,000,000 of arsenic or more than 5 parts per 1,000,000 of lead are illegal, as well as those containing harmful or deleterious ingredients. Misleading or deceptive newspaper or other form of advertising is prohibited. When the essential constituent is a compound of aluminium, the baking powder must be labelled "alum" baking powder, and the presence of acid phosphates must be indicated by the use of the term "calcium acid phosphate." It is recommended that the ingredients be named as follows: "This baking powder contains the following ingredients and none other: sodium bicarbonate, calcium acid phosphate, alum, and starch." A standard baking powder is considered to contain not less than 12 per cent. of available carbon dioxides. The sale of baking powder containing added albumin is prohibited. It is of interest to note that the use of egg albumin in baking powders has increased during the past few years. When asked why it was used some of the manufacturers frankly stated that the presence of albumin produced foam for use in demonstrating the qualities of the powder to the consumers at county and other fairs. Such a test is misleading and completely deceives the customer, who is thereby deluded into believing that the particular baking powder under test is greatly superior to others in its raising qualities. One manufacturer stated that the presence of albumin retarded the escape of carbon dioxide, and another claimed that the albumin increased the leavening power in the sense that it provided an additional amount of gas available for the leavening action. Professor Ladd believes that the test really shows nothing as to the real merits of two baking powders, as a baking powder free from albumin might seem to be the poorest in the lot, and yet it might yield the most carbon dioxide, uniformly given off.

RECURRENT ANTERIOR DISLOCATION OF THE ULNA.

IN the *Journal of the American Medical Association* of Sept. 6th Dr. A. C. Yoder has reported a case of a very rare result of injury—recurrent anterior dislocation of the ulna. A woman, aged 36 years, fell downstairs and hurt her left wrist on Feb. 28th, 1910. She immediately came to Dr. Yoder holding the forearm in median pronation with the hand and fingers slightly flexed. As there was a protuberance on the dorsum of the wrist he primarily diagnosed Colles's fracture. But on examination he soon discovered that this fracture was not present. The ulna was dislocated forwards and was easily reduced, but when the pressure was released the dislocation recurred. Motion in all directions was somewhat limited by the pain. The deformity on the back of the wrist could not be reduced by manipulation or pressure. An anterior splint was applied and rest was advised for several weeks. The splint was readjusted several times and then abandoned. The ulna remained in its normal place only when held there. The patient was finally advised to wear a wristlet, and to use her wrist and hand as much as possible. A skiagram taken a month after the injury did not show any fracture. In June, 1911, the patient returned complaining of pain and weakness in the wrist. Motion was practically normal, but the ulna was still dislocated. In March, 1913, the condition was as follows. Motion was practically normal, but there was some hyperextension and somewhat diminished flexion. The hand was used for all kinds of heavy work. The deformity on the back of the wrist persisted. When the hand was in supination the anterior lower end of the ulna projected anteriorly, but was freely movable and easily replaced; in fact, reduction occurred when the hand was pronated. The bone could be felt slipping into the sigmoid cavity of the radius as the hand passed from supination to pronation. It was concluded that the triangular fibro-cartilage and the anterior radio-ulnar ligaments were ruptured. The deformity on the back of the hand was difficult to explain. Several skiagrams

were taken and examined by experts. The conclusion was that there was slight backward dislocation of the radio-carpal joint, and that the carpal bones were crowded together and more or less rotated on their axes or even slightly dislocated. Other evidence of backward dislocation was the fact that the whole wrist and hand lay in a more dorsal plane than normal. Some of those who examined the plates held that the semilunar was dislocated. Recurrent dislocation of the ulna is very rare. Cotton in his classic work, "Dislocations and Joint Fractures," reports two cases, but does not think the lesion has previously been described. In one case the young girl "had as the result of trauma a slipping of the ulna on the radius with every movement of supination. See was suffering severely from ulnar neuritis as a result of constant irritation. Operative treatment was declined; mechanical treatment failed on account of the intolerance of the damaged nerve to pressure." There was also a Colles's fracture. The second case was "in all respects similar except for the neuritis. A cure was effected by an osteotomy that in effect tightened the radio-ulnar ligaments." Cotton adds that he has seen many cases in which there was a little looseness after Colles's fracture, "but ordinarily it is of no consequence." Hoffa has reported three cases of recurrent dislocation of the lower end of the ulna and Courtin the same number. The latter refers to one case mentioned by Hamilton. Dislocations of the radio-carpal joint are also rare. Stimson says that there is a total of about 70.

OLD ENGLISH HERBALS.

IN the mind of the average reader the word "herbal" generally calls up a vision of a magnificent folio full of illustrations. Such, for instance, are "The Great Herbal," the "herbals" of Lobel, Turner, Lyte, Gerard, and Parkinson. This last-mentioned book was more accurately speaking a treatise on gardening than a herbal proper, although its sub-title is "An Herball of Large Extent." It main title was "Paradisi in Sole Paradisus Terrestris," wherein the author's name was ingeniously concealed, for Parkinson (the spelling with "u" or "o" is of no moment) is, in Latin, "Paradisus in Sole." "The Great Herbal" appeared in 1526, but in the previous year—namely, 1525—there had appeared "Banckes's Herbal," which, says Mr. H. M. Barlow in an interesting paper now before us,[1] was a small quarto volume, and was the first of a series of small books, chiefly in blackletter, without illustrations, which appeared during the next 30 years. They were all more or less reprints of Banckes, with sundry additions and alterations, though after a fashion not unknown at the present day their publishers did not hesitate to associate the names of Macer, Linacre, and Askham with the book in order to give a fictitious importance to it. In remote country places, and we fancy in the East-end of London, a little book called "Napoleon's Dream-Book" may still be bought. Mr. Barlow has examined a number of these little herbals and has compared them from a bibliographical point of view. His researches have led him to the conclusion that the origin of the herbal "will probably be found in one or more of the numerous fourteenth or fifteenth century manuscripts on the virtues and properties of herbs which are still preserved in various libraries of this country." Banckes' Herbal and its successors are very little known, so that Mr. Barlow's careful description and comparison are a most useful link in the chain of medical historical bibliography. The remainder of his paper is devoted to the great illustrated sixteenth and seventeenth century herbals. These works, in addition to their medical ideas, are of great value as illustrations of the rise and progress of botanical drawing. Such are the beautiful plant drawings of Fuchsius, 1542, whose name is known to everyone by the fuchsia having been named in his honour. The large English herbals mentioned above were nearly all illustrated with figures by continental artists, and as the books are scarce it is useful to know that many of the illustrations will be found in a handy form in R. G. Hatton's "Craftsman's Plant Book."

[1] Old English Herbals, 1525–1640. By Horace Mallinson Barlow, Assistant Librarian, Royal College of Physicians of London. Reprinted from the Proceedings of the Royal Society of Medicine, 1913, vol. vi., Section of History of Medicine, pp. 108–149.

COMPLIMENTARY DINNER TO PROFESSOR SHERIDAN DELÉPINE.

Professor Delépine was entertained at dinner in the Midland Hotel on Oct. 10th by a number of those who have worked in his laboratory during the 21 years that he has been associated with the University of Manchester. An address signed by 200 of his former pupils was presented by Dr. W. J. Howarth, who expressed affectionate regard for Professor Delépine, pride in his scientific attainments, and deep admiration of his work for the University and for the community in which he has so fruitfully laboured. And, indeed, the public health department, in whose construction Professor Delépine has so much assisted, is one of which the University and the City of Manchester may be justly proud, while it has served as a model for many subsequent institutions. Dr. Newsholme, principal medical officer of the Local Government Board, presided, and in his remarks referred to the inspiration which they owed to Professor Delépine and to the value they attached to his pioneer work in applying pathology to public health work. Other speakers testified to the services of their guest as a scientist, teacher, and organiser, to his great success in training medical officers of health, and to the many important positions as public health officers that were held by his former pupils. Dr. J. Niven, medical officer of health for Manchester, said that Professor Delépine had made in Manchester a great public health school, probably the finest in this country, and much less than the usual allowance for local patriotism has to be made here.

RECOVERY FROM TUBERCULOUS MENINGITIS.

RECOVERY from tuberculous meningitis is very rare; only a limited number of cases in which the diagnosis was beyond doubt has been recorded. In the *American Journal of the Medical Sciences* for July Dr. R. L. Pitfield has given notes of the following case. A man aged 55 years was admitted into hospital with symptoms of meningitis, from which he had suffered for four or five days. He was very tall, measuring over 6 ft. 4 in., but far from robust. He was delirious, and there were retraction of the head, scaphoid belly, and tache cérébrale. At each apex there was evidence of tuberculosis, and the history indicated that the disease had existed for 10 years. The present attack began with violent vomiting, unendurable headache, and pains in the arms and legs. Kernig's, Oppenheim's, and Babinski's signs were present. The pupils were contracted and fixed. Lumbar puncture was performed and 80 c.c. of fluid spurted out. It was bloody from puncture of a small vein, and contained three acid-fast bacilli which, in view of the pulmonary tuberculosis, were assumed to be tubercle bacilli. The pulse was 70, respiration 20 and jerky, and the temperature 99° F. The urine was bloody and contained albumin and casts. Marked improvement followed the withdrawal of the fluid. The spastic symptoms slowly receded. The mind became clear in a few days and the headache disappeared. Thirty grains of urotropin were given daily. After three weeks' stay in hospital, to the amazement of everyone, he suddenly got up, asked for his clothes, and returned home. He then had some rigidity of the neck

and some evidence of Kernig's sign. Two years later he was able to conduct his business and there was no sign of meningitis. Dr. Pitfield considers that the fact that he was an adult and infected with a low-grade form of tuberculosis contributed to his recovery. Perhaps the most interesting case of recovery from tuberculous meningitis is one reported by Rumple, who at the Aerztlicher Verein, Hamburg, exhibited the brain of a boy who died from phthisis. At the age of 9 years he had acute meningitis, with retraction of the head, hyperæsthesia, absence of knee-jerks, double optic neuritis, ptosis, and palsy of the external recti. Lumbar puncture yielded a fluid containing tubercle bacilli. The boy was treated by repeated lumbar puncture and recovered. Though for some months dull and stupid, he eventually recovered his normal mental powers and was able to keep pace with other children at school, while all physical signs disappeared. For four years his health remained good. He then developed a tuberculous abscess in the axilla, phthisis followed, and he died eight years after the onset of the meningitis. At the necropsy it was found that the membranes over the fissure of Sylvius on either side of the brain were thickened and glued together, but no miliary tubercles were visible. Another case was reported in our columns last year by Dr. W. Tyrrell Brooks and Dr. A. G. Gibson.[1] Dr. Pitfield gives 29 cases (including the one under his care) of undoubted tuberculous meningitis in which recovery took place. In 10 a necropsy confirmed the diagnosis, and in 18 tubercle bacilli were found. In 4 tubercles were seen in the choroid. He estimates that recovery takes place in 1 in 200 cases of tuberculous meningitis. In several of the Reports of the Phipps Institute McCarthy states that he frequently found evidence of healed tuberculosis of the nervous system in persons who eventually died from phthisis. As to treatment, Dr. Pitfield recommends feeding by the nasal tube, administration of morphine for the pain, and of urotropin, as this is decomposed into formaldehyde which is found in the cerebro-spinal fluid.

MEDICO-LEGAL WORK IN CALCUTTA.

WE have received a reprint from the *Indian Medical Gazette*, Vol. XLVIII., of a paper by Major O. St. John Moses, I.M.S., entitled "Review of a Year's Medico-legal Work in the Calcutta Morgue, 1912 (including Comparative Figures for the Triennium 1910-1912)." There is much that is interesting in medico-legal work in India, as certain forms of death are met with which are peculiar to that country and are rarely if ever met with in England. During the year 1912 252 cases were sent up by the police for post-mortem examination as cases in which death appeared to occur under more or less suspicious circumstances. Under the heading of natural causes was one of cerebral apoplexy in a young Mahomedan male, aged 12; the boy was to all external appearances quite healthy, and there was an entire absence of all history of violence. Another case of interest was that of a Hindu male, aged 48, who died from cerebellar apoplexy. Each hemisphere of the cerebellum was ploughed up by a blood-clot, which in the case of the right hemisphere was of about the size of a small orange. Spontaneous rupture of the spleen has been stated to occur fairly frequently in India. One case came to Major Moses's notice in 1912, but it was the only instance of this nature met with in the three years 1910 to 1912. The remarks on opium poisoning are of interest. There was, as in previous years, a great preponderance of opium cases over all other cases of poisoning. Major Moses is emphatic in urging that everything possible should be done to place such a convenient and apparently popular means of self-destruction out of reach of the class among whom such a crime as suicide is of most frequent occurrence. A large number of poisonous substances are sold in the "pashari's" shop and in the bazar generally without restriction or licence, and it is much to be regretted that these poisons, especially opium, are so easily procurable by ordinary persons who might want them for unlawful purposes. As Major Moses says, the question resolves itself into the framing of a regular Sale of Poisons Act, whereby the State would do all that lies in its power to restrict the procuring of poisonous substances and to diminish the incidence of crime at any rate by such means. Amongst the native races, however, this would probably be a matter of great difficulty.

[1] THE LANCET, Sept. 21st, 1912, p. 815.

THE OHIO AND MISSISSIPPI FLOODS.

WHEN the great floods of March and April occurred in the United States this year in the valleys of the Ohio River and the Mississippi an immediate call was made for help from the National Guard, which parallels our Territorial Force, and Major Charles Lynch, of the Medical Corps, United States Army, has given in the *Military Surgeon* for August an account of the work then done by the medical department. It was real active service. Conditions changed rapidly; a town in safety one day and helping others was on the next day in dire distress. Railways and roads were cut, and to bring help required enthusiasm and ingenuity. There was plenty of initiative, and the help given was most valuable. To begin with, many were saved from drowning and also from starvation, but the work of the medical department appeared most conspicuously in the prevention of disease. When a city, being flooded, was taken in hand little could be done beyond providing food and shelter till the water fell, then the place was divided into districts, in each of which the sanitary *personnel* went round as organising inspectors and filled out forms reporting conditions of houses and offices, presence of sick, especially of infectious disease, and measures required. This had to be done quickly. In Hamilton, Ohio, 4000 reports were on file in two days. The town was gone over four times while cleaning was going on busily. Leaflets were issued directing boiling of all water, removal of mud, and formation of temporary privies if needed. Dead animals were burned, but a shortage of fuel sadly impeded some of the orders. The precautions, however, averted the danger of an outbreak of typhoid fever, and the infectious disease that gave most trouble was cerebro-spinal meningitis. Major Wadham describes the management of an epidemic of this disease amongst flooded out negroes at Deckerville, Arkansas. All were living in crowded railway wagons standing on a high embankment just above the water. No isolation was possible, but the four cases injected early with Flexner's serum recovered; the two not seen till the fifth day died. Preventive inoculation also limited the extension of the disease.

SULPHUR MINERS AND PHTHISIS.

IN the discussion at the Section of Hygiene and Preventive Medicine of the Seventeenth International Congress of Medicine on the Effects of Dust in Producing Diseases of the Lungs, Professor Carozzi, of Milan, is reported to have said that workers in the sulphur mines of Sicily, however seriously affected with pneumoconiosis and chronic lesions of the bronchi, hardly ever suffered from pulmonary tuberculosis. In this connexion the work recently published by Dr. Alfonso Giordano[1] affords some interesting information. He holds

[1] La Fisiopatologia e l'Igiene dei Minatori. By Dr. Alfonso Giordano, Professor of Mining Hygiene, University of Palermo. Issued by the Ministry of Agriculture, Industry, and Commerce. 1913. Published by G. Bertero and Co., Rome. Pp. 357. Price 3.50 lire.

that the question whether sulphur possessing disinfectant properties can hinder or favour the growth of Koch's bacillus is not yet decided. From remote times sulphur has been burnt with resinous wood in the form of incense at religious rites as a purifying substance. It was also recognised as a disinfectant by the ancient Greeks, for, according to Homer, Ulysses fumigated with sulphur the chambers in which lay the corpses of the Proci, and Pliny relates in his "Natural History" that rock sulphur was used in the ceremonial consecration of houses. Galen used fumigations of orpiment in the treatment of consumptives, who in his time were also sent to Stabia, near Vesuvius, in order that they might inhale the air impregnated with sulphurous vapours. On the other hand, sulphur has been blamed for producing conjunctivitis and causing irritation of the respiratory mucous membrane. Piccinini from his observations of sulphur workers arrived at the conclusion that sulphurous vapours had a favourable influence on the general condition of the organism, and particularly on the respiratory system, while Dr. Burruana, in a report on the diseases of the Sicilian sulphur miners communicated to the first International Congress on Industrial Diseases, stated definitely that phthisis was not met with among them for the reason that the sulphurous anhydride inhaled by them prevented the development of Koch's bacillus. It has long been known that sulphur miners expectorate a bluish-grey sputum, and Dr. Giordano, led by this fact to investigate its pathological histology, had his attention fixed by the forms of the sulphur crystals, the sharp points of which penetrate the pulmonary tissue and carry there those pathogenic micro-organisms which happen to be in the mucous membrane. He found Koch's bacillus associated with pneumoconiosis in the peculiar sputum in greater or less quantity. Considering the squalor and poverty of the miners it must be expected that there should be more or less tubercle among them, but whether the sulphur acts as a preventive to its development there is not enough evidence to show. In the air outside the mines 500 or more pathogenic organisms were found per litre, while in the deeper galleries the number diminished considerably to about 20 or less. While B. coli and B. typhosus were plentiful, the tubercle bacillus was absent. Probably these facts and the well-known antiseptic properties of sulphur have suggested what there are not enough available statistics to prove.

THE SANITARY CONDITION OF CINEMATOGRAPH THEATRES.

THE extraordinary multiplication of cinematograph theatres, which spring up with fungus-like proliferation, and often under conditions quite unwholesome for human life, renders it imperative that steps should be taken to safeguard the health of those who frequent them. We have already called attention to this subject in THE LANCET, and we repeat here that it is not to the cinema theatre as such that we take exception, but to the way in which many shops and other buildings totally unsuited to the purpose are being converted into these places of public congregation. From the sanitary point of view the most important aspects of the question centre in adequate opportunities for throwing open the building to the penetration of disinfecting light, in proper ventilation, and in the provision of a sufficient cubic airspace for the audience that assembles therein. In all these qualities many, if not most, of the converted shop cinema shows are wofully defective, and the problem of dealing with them is becoming daily more urgent. Chicago is wrestling with this problem with American resourcefulness. The *Bulletin* of the Chicago School of Sanitary Instruction for Sept. 20th, published for free distribution by the Department of Health, announces that all picture theatres that are proved on investigation to be satisfactorily equipped in this matter will in future receive a certificate to that effect to be displayed at the ticket office, and the public are cautioned to patronise only those theatres showing this certificate. Below the certificate is a picture of two Petri plates taken respectively from an unventilated and a ventilated theatre, the first of which shows 250 bacterial colonies, the latter 5 only. If it is not possible at the present stage of affairs to compel all cinematograph theatres to obtain a licence to be granted only on evidence of their sanitary efficiency, at least those that on examination are found to be in such a state might be furnished, as is done in the case of certified milk, with duly attested evidence of the fact to which all those who can obtain it would be only too glad to give prominent place as a special attraction to their prospective patrons.

WE learn with much regret of the death at the early age of 43 of Major H. C. French, R.A.M.C.

THE demonstration by Dr. Hideyo Noguchi which was to have been held at the Royal Society of Medicine on Monday afternoon last has been postponed on account of Dr. Noguchi's illness until Monday next, Oct. 20th, at 5.30 P.M.

AT the opening meeting of the coming session of the Society of Tropical Medicine and Hygiene, which is held this evening, Friday, Oct. 17th, at 8.30 P.M., at 11, Chandos-street, W., Sir R. Havelock Charles will deliver the Presidential address on Neurasthenia and its Bearings on the Decay of Northern Peoples in India.

FOUR Gresham lectures on Harvey, Darwin, and Huxley will be delivered on Tuesday, Oct. 28th; Wednesday, Oct. 29th; Thursday, Oct. 30th; and Friday, Oct. 31st, by Dr. F. M. Sandwith, Gresham Professor of Physic, at the City of London School, Victoria Embankment, E.C. The lectures are free to the public and will begin each evening at 6 o'clock.

WE regret to record the death on Oct. 13th of the distinguished psychiatrist, Sir John Batty Tuke, M.D., representative of the Royal College of Physicians of Edinburgh on the General Medical Council, and formerly Member of Parliament for the Universities of Edinburgh and St. Andrews. An obituary notice will be published in our next issue.

SCHOOL MEDICAL INSPECTORS.—A meeting of assistant school medical officers and school medical officers engaged in the medical inspection of school children, convened by Dr. C. W. Hutt, was held on Oct. 10th at the offices of the Society of Medical Officers of Health, under the chairmanship of Dr. Herbert Jones. Those actually engaged in the work of medical inspection of school children were well represented. In the course of the discussion the advisability of school medical officers and assistant school medical officers joining the Society of Medical Officers of Health was suggested on the grounds that the society can place at the disposal of its members an organisation which is the result of the experience of many years; it has considerable funds at its disposal, in addition to a well-established journal. The chairman pointed out that the constitution of the Society of Medical Officers of Health permitted any medical practitioner, male or female, engaged in the medical inspection of school children to become a member. It was resolved to form a group within the Society of Medical Officers of Health of medical officers engaged in the school medical service in order that the views of medical inspectors of school children should be adequately placed before the Society of Medical Officers of Health. Dr. C. W. Hutt and Dr. A. Ashkenny were appointed to act as honorary secretaries for the group *pro tem.*, and were instructed to inform the council of the society of the formation of the group, and to make arrangements for the first meeting of the group to take place on Nov. 7th.

THE MEDICINE OF THE BABYLONIANS AND ASSYRIANS.[1]

BY PROFESSOR MORRIS JASTROW, JUN.,
PROFESSOR OF SEMITIC LANGUAGES IN THE UNIVERSITY OF PENNSYLVANIA.

OUR knowledge of the medicine of the Babylonians and Assyrians is derived almost exclusively from the great library of clay tablets gathered in his palace by King Ashurbanapal of Assyria, who ruled from 668 to 626 B.C., and which was discovered by Sir Austen Henry Layard in 1849 in the course of his excavations at the Mount of Kouyunjik, opposite Mosul, the site of Nineveh, the capital of the later Assyrian empire. About 30,000 fragments of the bricks, or clay tablets, of the collection, which may well have numbered over 100,000 when complete, have found their way to the world's greatest treasure house, the British Museum. The term "library" may justly be applied to the collection, for there is scarcely a branch of knowledge that is not in some way, and to some extent, represented. Through the remains of the collection we are enabled to form an estimate of the intellectual achievements of both the Babylonians and Assyrians, for although the tablets date from the comparatively late reign of Ashurbanapal, the collection represents, for the larger part, copies made from older originals by the scribes of the Assyrian king who were sent to the temples in the south to copy the literary remains of the past that had been gathered in the course of many centuries in the archives of Babylonian temples.

Included in the collection are several hundred medical texts—indeed, at least 500 fragments may be placed in this category, though, for a reason that will presently become clear, the dividing line between a medical text and an incantation on the one hand, or an omen text on the other, cannot always be sharply drawn. Outside of Kouyunjik very few medical texts have come to light; one of the few specimens it will be my privilege to place before you this afternoon. No doubt this paucity of medical texts outside of Nineveh is accidental, for the medical section in the royal Assyrian library is clearly of Babylonian origin.

The Age of the Medical Tablets.

We have no definite means of determining the age of the medical tablets from which the scribes of Ashurbanapal made their copies. A general feature of these texts, which holds good, however, for all the other sections of Babylonian-Assyrian literature, is their composite character, containing, by the side of later elements, much that is far older. It is characteristic in general of the literary productions of the ancient Orient that the old is preserved alongside of the new; the pentateuchal codes of the Old Testament may serve as an example, where often, in the same chapter, very ancient practices, revealing in an unmistakable manner the primitive ideas on which they rest, are incorporated in the laws that belong to a far more advanced and later age. So in the medical texts of the royal library we have the accumulated experience of the past combined with the science of the age in which the compilation was made. If dates are desired one may say in a rough way that the treatment of disease as revealed in the medical texts of Ashurbanapal's library must refer to a period of at least 2000 B.C. The proof for this is to be found in the famous code of Hammurabi, dating from circ. 1950 B.C., in which not only the word for physician, *Asu*, signifying "healer," occurs, but where we find included, in the portion of the code devoted to injuries, the laws in regard to the fees for surgical operations, as well as the fines for fatal errors on the part of the surgeon. No doubt you are familiar with those regulations which, curiously enough, fix the fee in the case of a successful operation according to the station occupied by the patient. The ordinary freeman pays, e.g., for an operation on the eye 10 shekels (less than £1), while a member of the ruling class gets a reduction of 50 per cent., and in case the operation is performed on a slave the owner of the slave pays 2 shekels. The punishment for the failure of an operation, on the principle that the physician had no right to take the risk, similarly varies according to the position of the patient. If he be a slave who in consequence of the operation dies, the surgeon is to replace the slave by another; if the slave loses an eye the physician must pay one half of the value of the slave. If, however, the eye of a freeman is destroyed as a result of the operation the procedure is quite simple—the physician's hand is cut off. Such regulations point, on the one hand, to establishing medical treatment, but, on the other, in the inclusion of surgical operations among "injuries" and in the attempt to apply the *lex talionis*—the legal *quid pro quo* principle—to medical practice, there is revealed an aspect of medicine distinctly primitive, and which warns us against going too far beyond the time of Hammurabi for the beginnings of medical treatment, except as an accompaniment of incantations and magic rites. The circumstance, too, that the code of Hammurabi makes no provision for other forms of medical treatment than surgery may be taken as an indication that at that period medicine in general had not yet developed to the stage in which we find it in the medical texts proper.

Before leaving this subject it may be interesting to point out as an indication of the beginnings of specialisation in surgery that the code distinguishes between the ordinary surgeon and the veterinary, the latter being spoken of as "the ox or ass healer"; and, on the other hand, in the medical texts so far published surgery is not introduced. It would seem from this that the physician as surgeon was sharply differentiated from the healer of diseases, and perhaps not placed on the same level as the latter.

[Professor Jastrow here dealt with the two avenues of approach leading to medicine—namely, incantations accompanied by magic rites on the one hand, and divination practices on the other. He then continued:—]

The Character of the Texts.

The medical texts in Ashurbanapal's library, to which we are now prepared to turn, reveal in their phraseology the attachment to the two sources whence they are derived—incantations and divination practices. The terms used to indicate that someone is troubled with a disease are derived from the "incantation *motif*"—namely, "eating and seizing." Pain is when a man's head, stomach, bowels, liver, or any other portion is being eaten, or, more literally, that someone is eating a part of the body. The expression finds its natural explanation as a transfer of medical diagnosis to the belief that a demon is gnawing at some part of a man's body. The other term, "seizing," as, for example, that a man is "seized" with a fever, a headache, or the like, is similarly derived from the theory that a demon has taken hold of a man's head, stomach, breast, and so forth.

Interspersed with the remedies are incantations and magic rites, and we are constantly surprised at finding, in connexion with prescriptions of medicinal potions or mixtures, such directions as that the patient should put a hair taken from an old woman into his mouth, or that he should swallow the mixture while holding it in his left hand, and drink it to the accompaniment of an incantation. Lastly, the texts themselves are compilations from various sources. The aim of the compilers is to gather the experience of the past. We have in the medical texts the description of the physical ailment followed by a larger or smaller series of violent remedies. It was the business of the physician to select in each case one that, in his judgment, would be the most likely to bring about results, or he would try them all in some order of succession in the hope of finding one to fit the case.

Now, while there are many hundreds of medical texts that still lie unpublished in the British Museum, it is, I think, perfectly safe to say that the general principles of medical treatment and the general character of the remedies applied as resulting from the material already at our disposal, will not be essentially effected. Progress will be rather in the direction of identifying the substances used as drugs. This problem constitutes at present the most formidable obstacle to a complete understanding of the medical texts. In a purely formal manner we may distinguish two classes of these texts—those in which incantations play a secondary part, being merely, together with magic rites, accessories to the treatment, and those in which incantations and rites are quite as prominent as, and indeed overshadow, the treatment. I am inclined to regard the latter as considerably older than

[1] A lecture delivered in the Section of the History of Medicine of the Royal Society of Medicine on Oct. 10th, 1913. It will be published in full with copious extracts from the Babylonian-Assyrian medical texts in the Proceedings of the Society.

the former, and it will, I think, be regarded as natural to find in later texts the medical aspects more largely emphasised and the incantation element gradually reduced in proportion.

Remedies for Diseases of the Stomach, &c.

We have not yet discovered in the medical literature of Babylonia-Assyria any compilation corresponding to such extensive and systematic note-books like the papyrus *Ebers* or the Berlin papyrus in Egyptian medical literature, though it is quite likely that such complete compilations exist. We have, however, portions of a number of series, each one of which covers several tablets, and that deal with a variety of diseases. One of these, known from the opening words as "When a man has some internal disease," deals, so far as we can judge from the portions published, with a variety of troubles having their seat in the stomach, intestines, and liver. The tablet begins with the diagnosis of a cold which has settled in the stomach: "If a man is sick of a cold, which has turned into stomach pains, let him compound 'pestilence' root, liquorice root, *Tar-mush* plant" (perhaps the bean) "*Shi-man*, *Shi-shi*, *Tu-mu*, and 'tongue' plant—these seven drugs placed in wine let him drink, as the star rises" (i.e., at night and in the morning) "without food and he will recover."

Leaving aside the identification of these plants for the present it will be seen that we have here a simple prescription directing the physician to prepare a mixture of drugs made from roots and plants to be taken as a potion in the morning and evening without food, or, as we would say, before his meals. There is nothing suggesting any connexion with the magic ritual. In the next paragraph, however, directions for a magic rite accompanied by an incantation are set forth. The one who has stomach pains has to be taken during his illness on a boat, and a series of incantations, technically known as "house of light," are to be pronounced over him, and, it is added—precisely as in the case of the potion—"he will recover." There follow a series of variant medicinal descriptions and directions for the same trouble, which illustrate the leading principle of these texts, to put together on the basis of past experience as many remedies as possible. No differentiation appears to be made as to the stage of the disease at which the one or the other remedy is to be administered. On the other hand, the enumeration reveals some interesting methods of procedure. "If the same is the case" (indicated by the repetition of the sign) "he should suck the white meat of a swine without other food, and he will recover. If *ditto*, let him take liquorice root in water without food, and he will recover. If *ditto*, let him pound salt with water and drink it without food and he will recover. If *ditto*, let him mix *Aman* salt" (in all probability the origin of our *Sal ammoniac*) "without food, and he will recover. If a man has stomach pain, let that man kneel on his feet and have burning juice of cassia poured over him, and he will recover. If *ditto*, let him kneel on his feet and let cold water flow over him. If *ditto*, place his head downwards and his feet up, strike his cheek forcibly, rub him violently, say to his stomach, 'Be good'; with the left thumb manipulate his hand 14 times, 14 times manipulate his head, and roll him on the ground. If *ditto*, mix *male* pestilence root, liquorice root, *Shi-man* plant, *Tar-mush* plant, *Mashtakal* plant and *Cynoglosson*, and either in water or in wine let him drink it." These eight remedies furnish a good bird's-eye view of the scope of Babylonian-Assyrian medicine. The use of liquorice root or of salts in stomach disorders will be admitted to be rational. Swine's flesh plays a prominent part in magic rites, and would raise a suspicion that this remedy is symbolical rather than therapeutic, to coax the demon out rather than to help the patient. The reference to the kneeling position, in order to relieve the tension of the muscles of the abdomen, is interesting, and so is the stimulation of the circulation by pouring hot or cold water over the patient, though the procedure seems somewhat violent. Still more drastic and yet having a rational basis is the effort to produce an equable circulation of the blood by placing the head of the patient low and the feet high, and by administering what was evidently a form of massage manipulation. Will it be regarded too fanciful if I suggest that the direction to encourage the stomach to accept the violent treatment by telling it "to be good" is to be explained as psychical—the natural impulse to accompany the physical exertion on the part of the physician by emitting some sounds?

Lastly, let me call your attention to the alternative to take the medicine in water or in wine, a valuable indication that the physician recognised the addition of the wine or the water as purely accessory. In most cases light wine rather than water is prescribed, evidently for the purpose of making something more palatable, precisely as physicians nowadays add some substance agreeable to the taste.

Tablet Showing Predominance of Magic Rites.

By way of contrast let me now take up a short specimen from the second class of medical texts in which magic rites and incantation formulæ predominate. A tablet belonging to a series for the cure of pain in the muscles of the joints begins with a case of rheumatism settling in the lower extremities. The following directions are prescribed: "Encircle water, taken from the Euphrates with rotten grain, place within the circle a *Sha-Shur* reed. Take a measure of corn, place it on the reed, and let the sick man sit on it. Fill a measure with rotten corn and put it on the reed and place the foot of the sick man on it, and cover the foot with a putrid broth made of the rotten grain." There is apparently described here a poultice of water and grain on which the man has to sit and which has also to be placed on his foot. This might at a stretch be regarded as a primitive method of easing the pain, but the manner in which the directions are given reveals the magic character of the rite and they are precisely of the same order that we encounter in pure incantation texts, where great stress is laid on obtaining water from a sacred stream such as the Euphrates was. The method of surrounding the water with an embankment of grain is likewise indicative of a symbolical rite. The emphasis placed upon the quality of the corn as bad or rotten, and that the broth or poultice is designated as putrid food, leave no doubt that the purpose of the mixture is to disgust the demon.

A Medical Text of the College of Physicians of Philadelphia.

As a third example in illustration of the general character of medical texts, I choose one which the College of Physicians of Philadelphia was fortunate to acquire about a year ago, and which it is my privilege, with the kind permission of the authorities of the Philadelphian institution, to bring before you for the first time. Its special interest lies in the fact that it does not form part of the Nineveh library, but represents a private possession of someone who, to judge from the style of the written characters, lived in the seventh century B.C.; the name of the owner is given at the close of the tablet, which turns out to be an extract from a large series, covering at least five tablets, and of which portions have been published by the British Museum authorities. By means of a comparison with this publication, I have succeeded in completing the defective portion of the obverse and in reading most of the badly weathered reverse. The writer evidently extracted for his own private purpose—presumably for his medical practice—such of the directions from the large handbook as seemed efficacious to him. The extract is from the first two tablets of the series dealing with the various forms of fever and of headaches. The word for fever is "fire," which recalls an interesting parallel in the Babylonian Talmud—the great ritualistic compilation of the Jews, which, by the way, is full of ancient medical lore—where the question is asked, "What is fever?" to which a Rabbi replies, "A fire of the bones"—the same expression, therefore, as is used in Babylonian-Assyrian medical texts.

The tablet begins: "If a fever seizes a man, localised in the nerves of the forehead, and affects his eyes, so that his vision is clouded, and he is inflicted with an acute inflammation, and his eyes water, pound one-third of a measure of thorn plant with crushed 'birth stone,' take one-third of a measure of it for the head that pains; knead with cassia juice, wrap it 'around the head,' attach it" (by means of a bandage) "and for three days do not remove." The remedy consists, as you see, of a compress, to be applied to the head, containing some burning substance to draw out the inflammation or perhaps to produce a counter-irritation. A number of variant remedies of a similar character follow, including what is particularly valuable—a wash of a certain kind of alkali. "Wash his eyes," the text reads, "until the tears cease to flow." Further directions are given to put a poultice of various ingredients around his head, to tie it with a strip of a coloured thread, to rub oil on his head, to keep him in a sheltered compartment, and to continue this

treatment for three days. Despite the difficulty of identifying all the drugs mentioned, enough ingredients of the various poultices are clear, such as fat, various salts and alkalies, to show that the main thought was to reduce the swelling, and by means of a wash or ointment to stop also the flow from the eyes. The careful treatment—to keep the patient in a dark or sheltered compartment, so as to remain perfectly quiet—should be especially noticed, as well as the accurate indications to keep the bandage in place by means of a strip of thread.

Our text then passes on to headaches, always regarded with great seriousness in antiquity, just because of their common occurrence. There is a special demon of headaches, "*Tiu*," whose functions cover the entire range from an acute pain to insanity. The Talmud, which I have already quoted, has a significant saying about headaches and other ills: "Any sickness, except intestinal trouble, any pain except heart spasms, any ache, except a headache," and it adds rather cynically, "Any malevolence except that of a woman."

The text continues, "If a man's head burns, his head oppresses him, particularly his forehead, compound" (text defective) "with oil; wrap it around his head, press it on tight, and do not remove for three days." "If ditto, take one third of a measure of a powder *Shurman* wood, 10 shekels" (here used as a weight) "of powdered *Suadu* wood, 10 shekels of cypress, 10 shekels *Kukru*" (perhaps chicory), "10 shekels of powdered cassia, 10 shekels of a certain kind of grain, 10⅔ shekels of dates, 10 shekels of thorn plant, 10 shekels of good standing wine, 10 shekels of another kind of flour; mix them together, knead with wine into a paste, crush it and strain it, take one third of a measure of it for the head which pains, knead it with cassia juice, wrap it around, attach" (by means of a bandage) "and ditto" (i.e., for three days do not remove). Towards the close of the text there is a particularly striking reversal to the older form of sympathetic magic in the treatment of disease, and so undisguised a reference to the belief in a demon as the seat of disease that I cannot resist the impulse to quote it. "If a man's forehead is affected and the demon in his body cries out" (one is reminded of the passages in the New Testament like Mark i. 23, and Luke, chapter iv., where demons are represented as "crying") "and does not depart, is not restrained through bandage or incantation (that is if all remedies fail) then slaughter a captured *Karka* bird, squeeze out its blood, take a bit of its fat and the skin of its crop, burn it in a fire, mix with the blood, seed, and pronounce the incantation 'evil finger of man' three times; sprinkle and rub on the side of the affected forehead and the breast."

The examples given will suffice to show the general character of medical treatment among Babylonians and Assyrians at its best and worst, the highest level reached, as well as the persistence of older methods. It is significant that even our physician who extracted the larger handbook included the old magic remedy in his copy as a remedy to be resorted to in the last instance, which reminds us that even at the present time it is not uncommon for the quack, the herb doctor, and the patent medicine man, who may be regarded as the modern representatives of the old Babylonian exorcisers, to be appealed to by patients in moments of despair, when rational remedies do not seem capable of affording relief.

Diseases mentioned in the Texts.

On the basis of the examples furnished we will be prepared to find a large number of diseases introduced into the medical texts, but, what is more, we also find differentiations between various aspects of a disease having its seat in some particular part of the body. Despite the fact that only a portion of the material in the royal library has up to the present been published, the number of diseases of which we have descriptions is considerable. An enumeration, which does not aim at completeness, shows us colds, indigestion, vomiting, diarrhœa, cramps, rheumatism of the joints, neuralgia, hæmorrhages, eye troubles, heart diseases, bilious attacks, and various stages of jaundice. The diagnosis in many cases is quite remarkably detailed, and reflects considerable care in observing symptoms. A case of indigestion, accompanied by vomiting, is described as follows: "If a man has a pain in his stomach and cannot retain food, which comes back through the mouth, and he has piercing pains in his bowels (?), and he is inflated and there is wind rumbling in his anus, and diarrhœa has set in, take to cure him," and so forth, and so forth. Naturally a condition of this kind may not only be due to various causes, but may be the accompaniment of various disorders. The medicine of Babylonia-Assyria reaches its limit in the description of the symptoms, but, on the other hand, this lack of differentiation in the diagnosis is compensated for by the large number of remedies proposed, which it is fair to presume reflect the experience spread over long periods which taught the physicians to be prepared for various causes leading to the same or to similar manifestations. Swelling, or distension of the stomach, with cramps and an inclination to vomit, is described as follows: "If a man's stomach is distended and at the same time the muscles seem contracted, and he is inclined to vomit, take," and so forth. A sour stomach, with rumblings and vomiting, is described as "If a man has expectoration and his stomach is swollen and emits cries" (the cry of the demon is again meant), "brings back food and drink, take," and so forth. More briefly we find the case, "If a man's stomach is full of acid."

The diagnosis of a more complicated form of stomach trouble involving the chest and liver reads, "If a man's chest hurts him, the stool is like urine" (that is, a very thin, watery stool), "his throat hurts him in speaking, he vomits—all his insides are affected, take"—and so forth. Still more detailed is the description of a generally disordered system, accompanied by fever. "If a man, without eating anything, is inclined to vomit" (that is, he is nauseated), "has much phlegm, the saliva that flows from his mouth is bitter" (that is, acidity in the stomach), "his face glows, his stomach is swollen, his body, his nose, and his arms on a cold day feel hot, food and drink cause pain, he drinks a great deal of water, he vomits, wind rumbles in his anus, the muscles of his body ache and seem weak, the fleshy parts are painful, whatever he eats does not agree with him, take"—and so forth.

Affections of the Liver.

Liver trouble, so common among men and animals in southern climates, naturally plays a prominent part in the general texts. The general term for an affection of the liver is "gall sickness" and the chief aim of the physician appears in such cases to have been to secure an opening of the bowels, so as to relieve the system of defectively assimilated food. An unusually large number of remedies, however, are set forth, pointing, as I venture to think, again to the recognition of many varieties of gall troubles, even though this does not come into view in the diagnosis.

Jaundice itself bears the name *amurrikanu*, which is the exact equivalent of our modern term, and is also the name which occurs in the Talmud (*yerakon*). We find in the medical texts a number of descriptions indicative of various stages in jaundice. "If a man is affected with yellowness of the eye and the disease spreads into his eye causing a flow of tears ..... his abdomen is swollen, he gives back food and drink, that man is affected all over by the sickness and will die." No medicinal treatment is prescribed in this case nor in the following: "If a man has yellowness of the eye, his head, his face, and all his body is affected to the root of his tongue, which is thickly coated, he will die." A simple definition of jaundice is added as a means of recognising the disease: "If a man's body is yellow, his face yellow, his flesh is progressively shrinking, that is *amurrikanu*." Another designation of the disease or a form of jaundice is *akhkhazu*, a term which is personified as the demon of a specific disease. The prescription reads: "When a man's body is yellow, his face is yellow and black, the root of his tongue black—that is *akhkhazu*." The dark colour at the back of the tongue was apparently looked upon as an important symptom of an advanced stage of the disease, though I have been unable to satisfy myself that this symptom is characteristic. *Akhkhazu* in an advanced stage is set down as hopeless. "When a man has *akhkhazu* his head, his face, his whole body, and even the root of his tongue is black. The physician should not treat him [literally, should not bring his hand to him], that man will die, he cannot recover."

Diseases of the Eye.

Coming to eye diseases which were so common at all times in the Orient, as they still are at the present time, we find a number of incidental references in connexion with headaches and fevers. No doubt among

unpublished fragments some will be found dealing specifically with eye troubles. "If the right side of a man's forehead is affected and the tears of his right eye are involved the tear sac is choked up, take bits of powdered turnip seed mixed together, pour cassia juice upon it, apply to the forehead, and he will recover. If the left side of a man's forehead is affected and the tears of his left eye are involved, pour *kitne* and *haldappanu*, add heated wine, apply to his head, and he will recover. If both sides of his forehead are affected and the tears of both eyes are involved take *kitne* and *haldappanu*, cassia, powdered turnip seed, mixed together with some kind of grain in a mortar, add cassia juice, bind the liniment or poultice to both sides of the forehead, and he will recover."

A distinct case of an injury to the eye with a detailed account of rapid progress is referred to in a letter of a physician, Arad-Nana, to Ashurbanapal, found in the Archive section of the royal library. The patient is a little son of the king, about whose condition the father seems much worried. The nature of the injury is not disclosed, but indications point to a wound above or below the eye which has been discharging pus.

Arad-Nana to the King my Lord.
Thy servant Arad-Nana hearty greetings to my King and Lord. May Ninib and Gula (the god of healing and his consort always invoked in the introductory phrase of medical letters) grant happiness and health to the King my Lord.
Greetings to the little chap whose eye causes him trouble. I put a bandage on his face. Yesterday towards evening I took off the bandage that had been applied, removing also the dressing below, and there was blood on the dressing as much as the point of the little finger. Whichever one of thy gods has done this his command has surely been heeded.
Hearty greetings. Let the King my Lord rest assured in seven or eight days he will be well.

Hardly any comment is needed to this very explicit letter. The physician has placed a dressing on the eye containing, no doubt, some ointment, and he has fastened the dressing by means of a bandage around the face of the patient. He reports that bandage and dressing were removed to observe the healing process; that he found the wound almost healed. Modestly, or shall we say in accordance with current beliefs, he ascribes the unexpectedly rapid cure to the intervention of some god, and confidently predicts a complete recovery within a week. This is only one of many letters of physicians found in an extensive collection of official reports to the kings, and since through such reports we enter, as it were, into the physician's workshop and can observe him in his relations to his patients, I venture to place a few more before you and which will also lead us to the next point to be considered—the methods of treatment.

Some Medical Correspondence.

Physicians in Babylonia and Assyria do not always agree in their diagnosis and treatment. There is a very human touch in the criticism passed by Arad-Nana in another letter upon a wrong treatment apparently prescribed by a colleague. It is again the king's son who is suffering from hæmorrhages of the nose. Arad-Nana has apparently been called into consultation to ascertain why the bleeding does not stop. He reports as follows:—

To the King my Lord.
Thy servant Arad-Nana hearty greetings to the King my Lord. May Ninib and Gula grant the King my Lord happiness and health.
Hearty greetings to the King's son. The treatment which we prescribe for him is to be given every two-thirds of a double hour during the day (that is every 75 minutes). ..... In regard to the bleeding about which the Rab-Mugi (a high official) has reported to me that yesterday towards evening there was much bleeding, the dressings are not properly applied, they stop up the nostrils but at the same time the blood flows into the mouth. Let the nose be plugged up to the back so that air will be held off and the bleeding will cease. If it pleases the King I will come to look at it to-morrow. Meanwhile may I hear good news.

Evidently an attempt was made to stop the bleeding by merely plugging the alæ, the result of which was that the blood flowed backwards and came out through the mouth instead. As the spot from which the bleeding came was not covered Arad-Nana's advice is to plug up the nose completely.

My last example of this medical correspondence, which throws such a valuable light upon the standing of the physician at the Assyrian court, strikes a familiar note—one that will arouse your sympathy for your colleague of 2600 years ago. The king is suffering from an attack of rheumatism which seems to have been very persistent and refused to yield to treatment. Naturally the blame is put on the physician, our same Arad-Nana, and curiously enough the latter confesses that he had not understood the nature of the trouble, but that he feels certain of getting at the root of it. Here is what he writes:—

The King my Lord continues to declare "the state of this sickness of mine thou dost not recognise, thou dost not bring about a cure." Now I confess that hitherto I did not understand this rheumatism (literally, sickness of the muscles), but now I seal this letter to send it to the King my Lord. Let it be read to the King my Lord and properly understood. When it reaches the King my Lord let a physician ..... carry out the accompanying directions. Let the King apply this lotion (evidently sent with this letter) and soon this fever will leave the King my Lord. A second and a third time it should be applied to the King my Lord. The King must see to this. If it please the King let it be done to-morrow morning. This disease is in the blood. ..... With the ointment which I will send the King let the King be rubbed at the appointed time.

Let me conclude this portion of my subject by reading to you the symptoms of a disease in one of the medical texts so perfectly described as to require no further comments except to note a total absence of a sense of humour on the part of the compilers—the diagnosis of a "drunk" with the same seriousness as a case of jaundice. Sandwiched in between a description of bowel and chest troubles we read: "If a man has taken strong wine and his head is affected and he forgets his words and his speech becomes confused, his mind wanders and his eyes have a set expression, to cure him take shi-shi and so forth [11 drugs which are enumerated] to be compounded with oil and wine before the approach of *Gula* [that is, in the evening] and in the morning before sunrise and before anyone has kissed him let him take it and he will recover." It is almost humiliating to be obliged to confess that of the 11 drugs introduced in this prescription, despite the fact that six are a very common occurrence, we cannot with certainty identify more than two of them.

The Medicinal Remedies Employed.

This brings me to the next point to be briefly considered—medicinal remedies. There are considerably over a hundred drugs according to the medical texts and lists so far published. That the number in use, however, was much larger is shown by long lists of drugs found in the text-book division of the royal library, and which furnish, therefore, a most valuable supplementary source for the study of Babylonian and Assyrian medicine. These lists, of which we now have a large number at our disposal, consist of enumerations of plants, herbs, woods, thorns, roots and juices, and stones, with explanatory comments attached, indicating at times the phonetic reading of the signs, at times the class of substance to which the names belong or the genus of which they are a species. Other explanations attached to the lists indicate the use to which the drugs are to be applied and with what they are to be compounded. From this enumeration it follows that the lists were drawn up by the priests as aids to the study of medicine to be used in the Temple schools for the training of those who were to take their place in the community as "healers." The number of drugs is thus increased to the volume of an extensive pharmacopœia, comparing favourably in extent with modern compilations; over 300 substances are mentioned. The largest share is taken by plants, and among those that may with greater or less certainty be identified are mint, rape, or colewort, cummin, caraway, cassia, onions, leek, and cynoglosson, which, curiously enough, bears a name that is an exact equivalent of the Greek term *lishan kalbi* (dog's tongue), grain, wheat, and a large variety of reeds and thorny plants. Indeed, so predominating is the use of plants—the seeds, the juices, and the leaves being utilised—that the sign for plant which is to be read *shammu* becomes the general determinative placed before all substances used as drugs in these long lists. Quite irrespective whether the drug is a wood, a shrub, or a vegetable, it is introduced by the sign *shammu*, which thus becomes the general term for drug, and passes over in this sense into the Arabic, Syriac, Aramaic, and Hebrew—no doubt under the direct influence of Babylonian and Assyrian medicine. Within the plants distinctions are made between garden growths and wild herbs. Next to plants we have a large number of trees and shrubs, the roots, twigs, bark, sap, and seeds of which were used. Among those which may be identified are the cedar, the cypress—though there is also a cypress plant—the tamarisk, the myrtle, the willow, and the olive. Thirdly, we have many mineral substances, including various alkalies and salts; and, lastly, many stones which were crushed and used as ingredients in concoctions,

and more particularly in ointments and salves. Among salts it is perhaps of special interest to note the occurrence of a salt *amanu*, which seems to be the source of our own ammoniac. It is a fair inference that the use of stones as amulets was a factor in their introduction into medicinal compounds, for the stones mentioned include those to which a special significance as protection against demons was ascribed. These stones are sometimes enumerated among lists of drugs, but in such cases the sign for *shammu* is usually replaced by the sign for stone, to be read *na* in Sumerian and *abnu* in Babylonian. A prolonged study of the *shammu* and *abnu* lists has convinced me that the Babylonians intended to indicate by the signs for these two terms the broad distinction corresponding to organic and inorganic substances. If this view should turn out to be correct it would lead us in our further attempts to identify the terms introduced in the long lists of stones beyond the purely mineral kingdoms, just as the plant list extends beyond the scope of the vegetable kingdom because of the generic use of the sign for plant to designate any kind of a drug. The lists also show us the extent to which drugs were imported from other countries. For example, among the thorns there are mentioned three varieties of *dadanu*, one as growing in *Subari* (an old name for Assyria), a second in *Kinakhkhi* (which is the Babylonian form of Canaan), and a third in *Melukhkha* (which designates a section of the peninsula of Sinai).

Similarly we have lists of salts, and again a series of drugs grouped together as varieties of *ninu*, which we can fortunately identify as mint. Others again are grouped together as growing in fields or as varieties of cynoglosson. Of special interest are lists of drugs with indications of the diseases for which they are to be used, and of the manner in which they are to be employed as liniments, or to be taken in wine, to be taken fasting, mixed with honey, oil, and strong drink, or in water or milk. A series of remedies are given in one of these lists for bites of a dog or a snake, or the sting of a scorpion, or a blow of some kind. Some of the remedies thus indicated are to be applied to the bitten spot, several are to be made into an ointment and placed around the neck, or to be taken in wine, or wine mixed with oil. In one case it is specified that the oil is to be heated; in another that the leaves of a plant are to be applied to the face of the sick person.

We have a long list of drugs to be used in the case of eye diseases, presumably as washes and ointments. Among these the root and seed of cynoglosson occur. Another list gives the names of a series of drugs to be used for diseases of the mouth, which include inflamed gums, swollen cheeks, and ulcers. Lists of this kind are usually arranged in three columns, the first furnishing the name of the drug, the second that of the disease for which it is to be used, and the third how it is to be used. Thus the drug "male pestilence wood" is a drug for sickness of the mouth to be placed on the mouth. Several plants, including turnip seeds, are enumerated as remedies for a swollen cheek. It is quite likely that these fragments belong to a series in which in succession the drugs for all diseases were enumerated, with indications for their use. To this series would then belong another tablet, of which only a portion has been preserved, setting forth drugs for diseases of the anus which are to be mixed with oil or fat or with sweetened wine, and to be applied to the anus, though in one case it is specified that the leaves of the drug are to be taken in wine. Several portions of this series would be represented by fragments dealing with diseases of the heart, of the head, and throat, with such interesting specifications as pain of the throat, cold of the throat, inflammation of the throat, swelling of the throat, heart spasms, enlargement of the heart, heartburn affecting the throat, and so forth. In the same way we find remedies for diseases of the nose, for miscarriages, for sterility, and, if my interpretation of a passage in this list is correct, for abortions.

Lastly, before leaving the subject, let me call your attention to specimens of prescriptions in these aids to the study of medicine, forming no doubt part of an extensive dispensatory that may have covered a large number of tablets and which gave in some systematic sequence prescriptions for various diseases that were more fully treated in the medical handbooks. The form of the prescription is very simple, an enumeration of the drugs with the indication of the disease. Thus we have a prescription of eight various drugs for heart disease; another of five drugs to be compounded for *akhkhazu*. Again, six drugs for jaundice. In comparing the substances mentioned for the two latter diseases it is of importance to note that they actually occur among the compounds mentioned in the medical texts.

The Determination of the Drugs.

It will have become apparent to you by this time that the chief problem besetting us at present in the study of Babylonian and Assyrian medicine is the determination of the hundreds of drugs that are found in the list and in the medical texts proper. The task is, indeed, a formidable one, because the names are generally written in ideographs—that is, with one or two signs representing the word. The ideographs themselves are either fanciful, as dog's tongue, fox wine, or vaguely descriptive, as "white" or "life" plant, "pestilence," and the like. It is only when the names are written in the lists or in the texts phonetically—i.e., spelt out by syllables—that we have a definite point of departure. At times the names reveal the character of the plant, but in most cases it is only if we can find a corresponding term in one of the languages cognate to Babylonian, such as Hebrew, Arabic, Syriac, and Ethiopic, that we can solve the problem involved. Now, fortunately, we have long lists of medicinal herbs, plants, woods, and roots in the medical literature of the Arabs. Similarly, the Bible furnishes us with the native names for the most common trees and plants. Supplementary to the Bible we have the great compilation of the Rabbis of Babylonia and Palestine, known as the Talmud, and which reveals, incidental to discussions on questions of ritual, an extensive medical terminology in Aramaic. Thirdly, we have medical compilations in Syriac literature, of which a most important and unusually comprehensive specimen has just been published by Mr. Budge, of the British Museum. Though Syriac as well as Arabic medicine and in part the medicine of the Talmud is based on Greek models and to a large extent merely an adaptation of the great medical treatises of Hippocrates and Galen and their followers, still a considerable amount of earlier native medicine, both by the Arabs and the Syrians, as well as by the Jews, is of the Talmudic age. We are, I think, quite safe in assuming that beneath the still unidentified hundreds of drugs in Babylonian and Assyrian medical texts and signed lists there lie concealed to a very large extent the same substances that have been fortunately identified in Egyptian texts. We should, therefore, expect to find aloes, acanthus, crocus, mastic, nasturtium, saffron, mandragora, pomegranate, and probably also absinth and opium.

The Nature of the Treatment.

Medical treatment among the Babylonians and Assyrians consisted, as we have seen, largely in the administering of drugs compounded of a varying number of ingredients and tested substances of therapeutic value. Drugs, drugs everywhere given in wine, or water, or milk, or oil, or in several of these substances. If this were all, our estimate of the medicine of Babylonia and Assyria would have to be summed up in the verdict that it had not passed beyond the range of treatment of disease purely on the basis of popular experience of the medicinal value of certain plants, herbs, roots, juices, oils, salts, alkalies, and woods. We have, however, more than sufficient evidence in the medical texts that the healers of Babylonia, as well as their Assyrian colleagues, had advanced to the recognition of other forms of treatment. Let me, in conclusion, set before you some methods revealed in these medical texts. You may recall that in extracts from texts dealing with stomach troubles we find such directions as to place the patient on his knees so as to relieve the tension of the muscles of the stomach; or to place the head low and the feet high so as to bring about a more even circulation of the blood. Such methods betray more than merely popular observation or experience and rest upon some study of the reasons for the phenomena manifested in disease. To the same level belongs the introduction of the enema as a means of relieving the patient, and which has generally been supposed to be the discovery of the Egyptian physicians. We find the enema given both in a warm and in a cold form, and the frequency of such ingredients as oil and honey clearly shows the aim of bringing about the soothing of the inflamed and irritated muscles as well as of the swollen fleshy portions. That the same mixture

is ordered to be taken both through the mouth and to be introduced into the anus may strike us as perhaps naïve, but the logic of the treatment is irreproachable. The aim of the enema was to reach portions that could not be attacked through the mouth. If the remedy was a good one it ought to work equally well, no matter in what way it was brought into the body. On the other hand, I am inclined to believe that the frequent injunction to sprinkle the patient with a mixture given as an enema is a reversal to primitive methods with a view of exerting an influence on the demon rather than on the patient. In other words, the sprinkling is a ceremony of the same order as the sprinkling of the blood on the altar or on the individual as prescribed in some of the codes of the Old Testament.

Of a different character is the direction to rub the stomach with the mixture or to pour it on the anus, or both. A case of this kind is set forth in the following language: "If a man eats and drinks to his fill and then his stomach cuts him (that is he has cramps) and his insides are affected and swell up and he becomes sick and he gets colic, to cure him take cedar bark, shurmon bark, sweet reed (something like sugar cane), *balluku* herb, myrtle, *haldappanu*, chop up these five plants, add wine, heat the mixture, pour it off, add honey and refine; you will let it cool, rub it on his stomach and pour it on his anus." Nothing could be clearer, and whatever the modern verdict might be with regard to the efficacy of such treatment it will be admitted that the preparation and use of this liniment, for such it was, rest upon a rational basis. The ingredients, especially the oil and the honey, were expected to act as emollients to relieve the contracted muscles and to reduce the inflammation. I have not been able to find any definite reference to the enema as a means of bringing about a definite opening of the bowels, though experience must have shown this to be one of the results. It was applied so far as the texts go for its soothing and healing effect, indicated by the general use of oil, which is so common as to warrant us in designating the oil treatment as one of the favourite remedies in Babylonian and Assyrian medicine for all stomach troubles.

I have already had occasion to refer to the use of massage as an aid towards relieving pain in the stomach, and in passing we may note the frequent reference to the use of salts and of alkalies and of various other drugs both to aid in furnishing the digestive juices and to bring about an opening of the bowels. A typical instance is put briefly: "When a man's liver is affected mix cassia in water, let him drink it and he will have a passage." Varying directions to effect the same end are added: (1) a large quantity of sweetened wine; (2) herbs in water; (3) salt to be taken either in water or wine; (4) chopped onions taken in water; (5) *nukkurtu* plant and onions mixed together and taken in wine.

Poultices, hot and cold applications, ointments and salves to be applied to various parts of the body are a further proof that the physicians of Babylonia and Assyria passed beyond the stage when medical treatment was limited to taking drugs inwardly, and that they must have developed at least some theory as to the reason for the relief to be expected through drugs externally applied. There are many instances of directions to mix drugs into a paste or a salve to be smeared on a cloth or a bit of leather and to be applied to some part of the body. A typical case of a head compress reads: "If a man has a headache and his vision is clouded take one-third of a measure of a kind of flour powder and crush, knead with cassia juice, wrap it round his head, attach it (with a bandage), and do not remove for three days."

A more elaborate poultice for headache consists of the juice of seven plants mixed with wine, kneaded with cornflour into a paste to be spread on the liver, wrapped around the head, attached, and to be kept there for several days. The directions are specific that the poultices are to be placed around the head and to be fastened with a bandage. In the case of stomach troubles it would appear that the poultice was simply placed on the affected portion, though sometimes it was also spread on cloth and attached to the body.

Diet and Other Matters.

Lastly, and as a third indication of the more scientific aspects of Babylonian and Assyrian medicine, let me give you a few illustrations of the diet prescribed for the sick in cases of indigestion in which the stomach refuses to retain food. The patient is to abstain from onions and leeks and garbi (perhaps another form of onion). This precaution is frequently prescribed and is generally combined with the direction to wash in pure water or with the juice of some wood that unfortunately cannot be identified. Physicians do not, however, always agree, and so we come across a case of vomiting spells in which just the contrary is recommended, that for three days the patient should not wash, and it is added he will recover.

A certain diet for stomach trouble appears to have consisted of two substances, one of which unfortunately cannot be determined owing to the defective condition of the tablet at this point, and the other is literally translated "the sediment of butter." Can butter-milk be meant? Another diet prescribed for stomach troubles consists of dates to be eaten in pig's fat or in oil. Again, in illustration of varying opinions among the physicians we find a diet of green onions and chicory ordered to be beaten up in water. In quite a number of cases quiet and rest are prescribed, the terms reading: "Let him rest quietly," or again, "Let him lie down and keep quiet"; and you will have noticed the frequency with which it is specified that medicinal potions are to be taken "without food"—that is, on an empty stomach, evidently with a view of giving the medicine a chance to have its full effect.

The Influence of Babylonian and Assyrian Medicine.

Here I must rest my case, and I feel that I have kept you as it is beyond normal endurance. I should have liked very much to touch upon the important question of the influence exercised by Babylonia and Assyria upon the ancient world. Briefly, let me say that the more direct traces of this influence are to be seen in the medicine of the Jews as revealed in the many passages of the Talmud in which medical treatment is discussed. The Jews of Babylonia and Palestine naturally came under the direct influence of Babylonian and Assyrian civilisation during the centuries (second B.C. to about the sixth A.D.) represented by the Talmudic medical compilations, just as we find such striking proofs of this influence in the pages of the Old Testament covering the earlier periods—in the popular traditions, in the customs, the laws, and the literature of the ancient Hebrews. Despite the introduction of the more scientific methods of Greek medicine, the Jews clung to the Babylonian and Assyrian conception of disease as due to demoniac possession. We find incantations and magic rites in the Talmud of precisely the same character as in the Babylonian and Assyrian literature, including even traces of what a German physician of the eighteenth century aptly called a Dreckapotheke. Such specific parallels as the frequent directions to take medicinal potions in wine can hardly be mere coincidence, and I have no hesitation in saying that the medicine of the Talmud reflects at almost every turn Babylonian and Assyrian influence. As for Arabic medicine, it would be surprising if we should not encounter some traces at least of methods and practices that were developed in the Euphrates valley, though of course the dominant factor in Arabic medicine is Greek science. The same is the case in Syriac medical compilations which are largely based on Arabic models and follow the methods of Greek physicians. The recent publication by Mr. Budge of a most elaborate medical treatise of Syria, to which I have referred, places students in a particularly favourable position for studying the relationship in this instance to Babylonian and Assyrian medicine. Let me at least point out that attached to the main treatise, which proceeds methodically to treat one disease after the other and to discuss the symptoms in the manner of Greek medicine, the compiler has added a long section on astrology in which, as in Babylonian and Assyrian Omen collections, are included prognostications as to the outcome and duration of the disease according to the day of the month on which an individual is taken sick. It is hard to resist the conclusion that we have here a distinct trace of Babylonian and Assyrian divination practices, just as we may recognise the direct influence of Babylonian and Assyrian medicine in another large section added by the compiler in which he has put together a most formidable array of remedies for all kinds of diseases and which he designates as native prescriptions. These remedies, furnished as supplementary to those embodied in the main part of the work, are clearly survivals of the earlier stage of medicine

prior to the introduction of Greek methods. We find as a matter of fact mixtures among these native prescriptions that remind us of those in the medical texts of Babylonia and Assyria. We come across the frequent direction to take the medicine in wine (though beer, as in Egyptian works on medicine, is also included). We find a considerable number of ingredients forming part of a Dreckapotheke, which suggests the survival of the endeavour to cure the patient by disgusting the demon, and we also have directions of a distinctly magic character. As a general point of resemblance between Syrian medicine and that of Babylonia and Assyria justifying us in seeking for further influences of the latter, I may instance the use of the Syriac word for heart, *libba*, precisely as the Babylonian *libbu* in the medical texts for the belly.

Closing Remarks.

And now it only remains for me to thank you for the patience with which you have followed this endeavour to sketch in outline the course taken by Babylonian and Assyrian medicine and to set forth some of its salient features. Considering that, as I have tried to emphasise with special force, medicine remained attached down to the latest days of Babylonian and Assyrian history to the demon theory of disease, that incantation rites continued to be regarded as an important accessory to medical treatment, and that divination practices further held in check the free development of medical science, it is, I think, a rather notable achievement that the healers of Babylonia and Assyria should have passed across the barren wastes of incantation rites and divination practices, and reached at least up to the borders of the promised land of genuine medical science. Indeed, we may perhaps go further, and on the basis of the medical texts and the various aids to the study of medicine in prescribing poultices, dressings, massage, diet and rest, assert that Babylonian and Assyrian medicine through some of its anonymous representatives, passed beyond the frontier and took possession of some of the outposts. The further steps, however, in the invasion of the territory of medical science were left to others—to the Egyptians at an early age, and more particularly, of course, to the great Greek physicians of the fifth and fourth centuries before this era.

OPENING OF THE MEDICAL SCHOOLS.

University College Hospital.—At this school there was no inaugural address, but on Oct. 1st when the session opened Dr. G. F. Blacker, the dean of the school, read an interesting report on the work of the past year. During the session, he said, 242 students attended the school, of whom 155 were new students. In response to an appeal issued to former students of University College and University College Hospital, a substantial sum had been collected to institute a memorial to the late Lord Lister, and a joint committee of University College and of University College Hospital Medical School was at present sitting to decide what form the memorial in the college and in the hospital should take. Sir John Rose Bradford, K.C.M.G., F.R.S., had been appointed a member of the Departmental Committee of the Board of Education appointed to inquire and report as to the steps by which effect should be given to the scheme of the Report of the Royal Commission on University Education in London. It was interesting to note that the recently appointed Advisory Council for Medical Research, in connexion with National Health Insurance, contained among its number seven past students of the hospital—viz., Sir Rickman Godlee, Sir A. Whitelegge, Sir Alfred Pearce Gould, Dr. Sidney Martin, Dr. Sidney Coupland, Dr. H. M. Richards, and Dr. T. C Stevenson. In the newly instituted department for mental diseases Dr. Bernard Hart had been appointed physician in charge, and in charge of the inoculation department, which had been opened owing to the generosity of Sir Harry Waechter, Bart., Dr. F. H. Thiele had been appointed. Dr. Blacker concluded his report with a reference to the success which had attended the meeting of the medical society in connexion with the school.

Charing Cross Hospital.—The annual dinner of the past and present students was held at Gatti's Restaurant on Oct. 1st, Mr. H. F. Waterhouse being in the chair. About 110 were present, and among the chief guests were the Hon. H. Fletcher-Moulton; Dr. Burrows, Principal of King's College; Mr. Robin Duff, chairman of the hospital; and Dr. Gordon Wilson. In proposing the toast "The Prosperity of Charing Cross Hospital and Medical School," the chairman said that they had passed through a time of great change and developments and the result was in all ways satisfactory and a matter for which they might legitimately congratulate themselves. The record of the school, both in academic distinctions and on the athletic side, was one of which all might feel proud. Two years ago Dr. William Hunter had been appointed dean at a time when changes were contemplated which were bound to affect the school for good or ill, and since that time there had been uninterrupted successes. The school was never in a more flourishing condition, and they could not too fully appreciate the services of Dr. Hunter, who grudged neither his time nor his health in maintaining its welfare. As regards the hospital, an event was foreshadowed which all would regret. He referred to the approaching retirement of Dr. F. W. Mott. For his part it would be unthinkable for Charing Cross Hospital to be deprived of the services of so distinguished a man, and if the committee could help it there would be no retirement. Dr. Hunter, in the course of his reply, expressed his appreciation of the enthusiasm and loyal support of all his colleagues of the school during the important developments and changes which had been effected in the past two years. It had been a source of peculiar gratification to the hospital and its school to have had the presence of the Lady Wantage—one of the oldest friends of the hospital—at their prize distribution that day, and to have heard her encouraging appreciation of the changes that had been effected. The Hon. H. Fletcher-Moulton, replying to the toast of "The Guests," proposed by Dr. T. W. Eden, said that reference had been made to his father in connexion with Lord Fletcher-Moulton's services to the medical profession during the sitting of the Royal Commission on Vivisection. He was sure that there was nothing of which his father was more proud than of having been the means of showing a number of persons that the doctors were actuated in their scientific researches by feelings alike of charity and of the good of humanity in general. The health of the chairman was proposed by Dr. J. Galloway in a speech full of historical learning and research, in which he drew a parallel between the position occupied by the ancient hostel of Charing and the present hospital. During the course of a most enjoyable evening Dr. Mott consented, amidst great applause, to withdraw his proposed resignation from the hospital staff.

St. Mary's Hospital.—The annual dinner was held at Prince's Restaurant on Oct. 2nd and was largely attended. The guests included Sir John Prescott Hewett, G.C.S.I., Sir Arthur Conan Doyle, and the Mayor of Paddington. Mr. Horace Sworder, of Luton, was in the chair, and, after the usual loyal toasts, proposed "St. Mary's Hospital and Medical School" in felicitous terms. In reply, Mr. Austen Leigh, chairman of the hospital board, referred to the events of the year, notably the rebuilding of the casualty department, the complete renovation of the drainage system of the hospital, and the proposed installation of a new mechanical lift for the use of operation cases. He commented on the increased importance of St. Mary's which would result from the migration to the suburbs of St. George's and so many other similar institutions. Sir John Broadbent, Bart., dean of the medical school, enumerated the more important successes of the year—the award of the Hungary Prize to Sir Almroth Wright, of the Nettleship Prize to Mr. George Coats, and of the Jacksonian Prize to Mr. F. W. Goyder. By obtaining at the M.D. examination of the London University the Gold Medal in Medicine, Dr. C. M. Wilson had brought to St. Mary's the eighth gold medal in nine years. The school was in a strong position, possessing among other assets, Dr. Ridewood and Dr. Senter, the only university readers in the subjects of biology and chemistry. The health of "The Visitors" was proposed by Dr. E. Graham Little, and was responded to in a witty speech by Sir Arthur Conan Doyle and by Mr. H. G. Handover, Mayor of Paddington, who paid a tribute to the invaluable services of the hospital in the rapidly increasing district which it served. Dr. Sidney Phillips, senior physician to the hospital, then proposed the health of the chairman, to which Mr. Sworder briefly replied.

Leeds School of Medicine.—The winter session at the School of Medicine of the University of Leeds was opened on Oct. 1st, when Professor C. S. Sherrington distributed the prizes and delivered an address on "The School of Medicine and the Provincial University." What advantage, Professor Sherrington asked, does the student in the provincial school obtain from enlistment in the Provincial University? The student himself, he said, would probably reply by instancing his opportunity to be examined not in alien laboratories and wards, but in those in which he had been taught and by teachers who had taught him. Yet, remembering the strictly scientific character of modern medicine, it was obvious that another advantage obtainable by the school from association with the University would be the provision of scientific laboratories on a scale of completeness which the isolated school could not furnish. Nowadays a career in medicine demanded knowledge for which the basis lay in the prefatory sciences of biology, chemistry, and physics. Further, the student had to possess first-hand acquaintance with the sciences specially attached to medicine—namely, anatomy, physiology, pathology and pharmacology. Each of these studies was costly, alike in money, time, and equipment. If the full cost of such studies had to be obtained from the student, the educational authorities would fail in one of their duties to the community, because these studies would then become an exclusive privilege of the wealthy few. By incorporating with the local university, the school of medicine legitimately extended its means of appeal and sources of support on the whole field of the public spirit of the province. Another benefit to the student was a wider circle of full studentship thus afforded him. The university offered him a great benefit of intercourse and intimacy with students not only within but also outside his own particular training. As student life was a miniature of the outside world though a less monotone one, students should be urged to see that each one of them entered thoroughly into the student life of the university as a whole, and the spirit of fraternity should embrace all classes gathered within the house of *Alma Mater*.

University of Edinburgh.—In opening the combined class of clinical medicine of the University of Edinburgh in the Royal Infirmary on Oct. 7th, Professor Sir Thomas R. Fraser said that beyond the usual subject-matter of the opening lectures he had before him an additional topic of great and possibly epoch-marking importance. This was the inauguration of certain changes in the arrangements and conditions of clinical instruction in the Royal Infirmary, which after several years of discussion had at length culminated in a settlement and agreement. As this agreement very closely affected the students of medicine and had, indeed, been made mainly in their interest and for their advantage, Sir Thomas Fraser described its salient points. 1. An incorporation with the University has been effected of the whole of the ordinary physicians, assistant physicians, and tutors into one concrete body, without distinction, in essential points, between University professors and extramural teachers. 2. The ordinary physicians have become university officials with the title of senior lecturers in clinical medicine; the assistant physicians as lecturers; and the tutors as University tutors or assistants. All of these teachers, along with the professors of clinical medicine, have thus been fused into one concrete body, to work together for one common purpose, and without the semblance of being two different bodies, each desirous it may be of maintaining separate interests. It is no doubt the case that the last University Commission granted to all University students the right of attending the wards and the instruction of the ordinary physicians on exactly the same conditions as those of University professors, but so long as there existed a University group and a separate extramural group a distinction has inevitably been made, which may have the disadvantage of limiting the full use of the medical wards and of the valuable teaching power available in the infirmary. Under the new arrangements all may now act for one common purpose; and unnecessary duplications of arrangements, with consequent weakening of resources, may now largely be avoided. 3. The new arrangements also include the appointment as examiners for University degrees of every one of the ordinary physicians, in future to be designated senior lecturers in clinical medicine. It is also provided that a limitation should be made in the number of students attached to each professor and senior lecturer. 4. Frequently the assistant physicians have almost limited themselves in their infirmary work to the out-patient department and to acting as substitutes to the physicians during their temporary absence. In the new arrangements it is provided that, while retaining these functions, these officers, now to be designated University lecturers, shall take more part in clinical teaching than before, shall assist the professors and senior lecturers in ward teaching, and, if required, shall also give clinical lectures. They will assume the position of the *chefs de clinique* in France and Germany. 5. Instruction in the niceties of special clinical work, largely in its scientific aspects, is in future to be consigned to the charge of the clinical tutors in coöperation with the University lecturers, and for this purpose rooms under five medical pavilions have been furnished with suitable fittings and apparatus, the former by the liberality of the managers of the Royal Infirmary and the latter by the University. Having thus outlined the leading features of the new arrangements, Sir Thomas Fraser pointed out that they provided a large supply of teachers and an ample complement of clinical materials. It might almost be said that there was a plethora of teaching power. If injudiciously used it would, indeed, be hurtful; if judiciously used it would add greatly to existing facilities for instruction and be of much value to students. Great evil could result if students permitted themselves to contemplate the advisability of attaching themselves to the cliniques of most or all of these seven professors and senior lecturers. That would be a fatal error. The lecturer believed, on the other hand, that a strict limitation in the number of teachers attended by each student was most advisable, and that in the earliest infancy of development in the knowledge of clinical medicine it should be an understood axiom that for a period of five or six months the student remain under the pupilage of only one physician in charge of wards. The new arrangements have been extended into the infirmary department of pathology, which also has now become incorporated with the University. The pathologists and their assistants have become University officials, the accommodation for the teaching of morbid anatomy has been greatly extended, and the arrangements for the work and teaching in the department have come under the direction and supervision of the Faculty of Medicine and the University Court. Sir Thomas Fraser concluded: "I have thus briefly directed your attention to important new arrangements for education in clinical medicine. They relate only to such an education as will impart the elements of knowledge adequate to qualify a man fitly and usefully to enter on the practice of our profession, and even to appreciate and assimilate the further advances which are almost daily being made to the great advantage of mankind. These advances are mainly the fruits of modern science, partly originated by observation at the bedside of patients, but matured by the extension of clinical observation into the laboratories of chemistry, pathology, bacteriology, and pharmacology. It has become important that clinical teachers should be capable of adopting the methods and resources of the laboratory in their work as physicians and teachers. They will thereby become more efficient in treating disease and imparting knowledge to students, and also in directing and themselves conducting the investigations from which is derived the information now demanded in the diagnosis and treatment of each case of disease. So vast is now this acquired knowledge, so protracted the time required for this investigation, that the opinion is extending in this country that in each large educational hospital there should be at least one teacher of clinical medicine who, while retaining the ordinary functions of a hospital physician and engaging to a moderate extent in public professional work, should devote his chief time and energies and thoughts to his hospital work, almost as restrictively as has become necessary in such University chairs as those of physiology, or chemistry, or pathology, or bacteriology."

THE LISTON VICTORIA JUBILEE PRIZE.—At a meeting of the Royal College of Surgeons of Edinburgh, held on Oct. 15th, this prize of £100 was awarded to Mr. John David Malcolm, M.B. Edin., F.R.C.S. Edin., London, for his investigation into the causes of shock.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF COUNCIL.

A QUARTERLY meeting of the Council was held on Oct. 9th, Sir RICKMAN GODLEE, the President, being in the chair.

It was resolved that Dr. H. P. Keatinge, director of the Egyptian School of Medicine at Cairo, be asked to convey the thanks of the Council to the Egyptian Government for presenting to the College a valuable series of "corrosion preparations" made with great skill and originality by Professor B. Wahby, and recently exhibited in the Museum of the Seventeenth International Medical Congress.

The best thanks of the Council were given to the Director of the Department of Agriculture at Washington for presenting to the College a collection of plants and drawings made by Dr. Edwin E. Smith to illustrate tumour formation, which were also exhibited in the Museum of the Congress.

The best thanks of the Council were given to Sir Thomas Wrightson, Bart., for presenting to the College a Leitz projection apparatus and a serial section of the human labyrinth.

The thanks of the Council were given to the authorities of the Egypt Exploration Fund for their gift of 24 skulls discovered during excavations in Egypt last winter.

Mr. CHARTERS J. SYMONDS, on behalf of the Committee on the Annual Report of the Council, submitted a draft copy of the report to be presented to the Fellows and Members at the annual meeting on Thursday, Nov. 20th. The report was approved and adopted.

Mr. G. H. Makins was appointed a member of the Committee of Management in the vacancy occasioned by the retirement of Sir Rickman Godlee.

ANNUAL REPORT OF THE COUNCIL.

The annual report of the Council of the Royal College of Surgeons of England, which is to be presented to the meeting of Fellows and Members on Nov. 20th next, has been published and contains a record of the work of the College in its various departments during the year ending August 1st, 1913. The resolutions which were passed at the last annual meeting dealing with the National Insurance Act and the question of the direct representation of Members on the Council of the College are recorded, together with the replies of the Council. They stated that they were glad to find that their action in connexion with the National Insurance Act had met with the approval and endorsement of the meeting. With regard to the question of the direct representation of Members, the Council expressed the opinion that, as their views on the subject were fully set out in their annual report of 1907, they did not think that any further statement from them was needed.

The Insurance Act.—In connexion with the Insurance Act the report states that meetings of the joint committee of the Royal Colleges of Physicians and Surgeons, the Society of Apothecaries, and the Medical Faculties of the Universities have been held, and resolutions have been passed. These resolutions relate to (*a*) the conditions set up by the Provisional Regulations of the Insurance Commissioners in October of last year; (*b*) matters concerning the professional conduct of medical practitioners; (*c*) the question of the Provisional Regulations being left largely in the hands of the Local Insurance Committees; and (*d*) the advisability of establishing tuberculosis centres in connexion with those hospitals to which medical schools are attached. The joint committee collected information regarding the working of the Act from members of the profession practising in various parts of the country with the view of memorialising the Government in the event of an Amending Bill being introduced. Owing chiefly to the late period of the session at which this measure was laid before Parliament last year it was thought no useful purpose would be served by presenting a memorial. In reference to the position under the Act of resident medical officers at hospitals (a point upon which the President, on behalf of the Council, had addressed a letter to the Commissioners), the following decision was given by the National Health Insurance Commissioners: "That resident medical officers at hospitals employed under the conditions referred to at the hearing in October, 1912, are not employed under a contract of service within the meaning of the National Insurance Act, and are accordingly not required to be insured thereunder, even if their rate of remuneration does not exceed in value £160 a year." With reference to a letter sent to the College early this year from the honorary secretary of the London Medical Committee, asking to be informed regarding "the attitude of the College towards such of its Fellows and Members as might become members of a registered trade union formed to advance the interests of the medical profession, and particularly as to whether the College would be likely to view their action adversely," the Council sent the following reply:—

> That, inasmuch as there is nothing in the charters and by-laws to prevent a Fellow or Member joining a registered trade union, the formation of such a union by members of the medical profession does not in itself appear to the Council to be a matter to which they can raise objections; and that the view which the Council might take of the conduct of any Fellows or Members in joining such a union, or taking part in its affairs, would depend on the objects with which it is formed and the methods it adopts to attain such objects.

The title of doctor.—An important item contained in the report is that mentioned under the heading "The Title of Doctor." It is here stated that the Royal College of Physicians have withdrawn the words in one of their by-laws forbidding their Licentiates to assume the title of "doctor" unless they held the degree of M.D. The Royal College of Physicians has thus adopted the same attitude in the matter as the College of Surgeons, which has never objected to its Members assuming the courtesy title of "Doctor."

Alterations in the regulations for the Fellowship.—During the period with which the report deals suggestions for alterations in the physiological part of the primary examination for the Fellowship have been submitted to the Council in a report from the board of examiners in anatomy and physiology for the Fellowship, and also in a memorial from teachers in physiology. These suggestions were referred for consideration to a large committee of the Council, and the recommendations of the committee have been approved and adopted. The clause in the regulations relating to the necessity of candidates attending "a course of practical physiology during not less than six months at a recognised medical school," has been altered to (*a*) a course of experimental physiology; (*b*) a course of chemical physiology; and (*c*) a course of histology at a recognised medical school. Other alterations are to the effect that two papers in physiology, each containing four questions, of which a candidate must answer only two, be set, and that two hours be allotted to each paper. The same arrangement is to be adopted for the written part of the examination in anatomy.—The Council have adopted the suggestion of the deans of the dental schools of London that candidates for the Licence in Dental Surgery of the College should be required to pass the Preliminary Science Examinations before commencing any part of the course of study and practice required for the Second Professional Examination. The alteration in the regulations will apply to all candidates who commenced their professional studies on or after Oct. 1st, 1913.

Alterations in the award of the Blane medals.—Alterations in the regulations for the award of the Sir Gilbert Blane medals have been made during the past year, and it is now provided "that one medal be awarded annually to the medical officer who obtains the highest aggregate marks at the examination for promotion to the rank of staff surgeon now held twice a year in connexion with the courses at the medical school of the Royal Naval College, Greenwich, the award to be subject to the approval of the Presidents of the Colleges of Physicians and Surgeons respectively and the Director-General of the Medical Department of the Navy." Previously two medals were conferred once in every two years on two medical officers of the navy "who in the time required shall have delivered to the proper office journals evincing the most distinguished proofs of skill, diligence, humanity, and learning in the exercise of their professional duties."

A centenarian Member.—The Council have sent their congratulations to Surgeon-Major Henry Benjamin Hinton, of Adelaide, South Australia, on attaining the age of 100 years. Surgeon-Major Hinton was born at Southsea on March 7th, 1813, and became a Member of the College in 1835. He served in India through the Mahratta and Sikh wars and during the Mutiny, and on retiring from the army lived at Launceston, Tasmania, and subsequently at

Melbourne, Victoria, before taking up his residence at Adelaide.

Finance.—The gross income of the College for the year amounts to £26,379, an increase of £539 on that of the previous year. The expenditure in respect of revenue for the year amounts to £22,261, and is £1508 less than in the previous year.

Museum and Library.—The report contains a full description of the progress made both in the museum and library of the College, and records the various donations and additions which have been made.

ANNUAL MEETING OF FELLOWS AND MEMBERS.

A meeting of Fellows and Members will be held at the College in Lincoln's Inn Fields on Thursday, Nov. 20th, at 3 P.M., when the report from the Council will be laid before the meeting. Fellows and Members can obtain copies of the report on application to the secretary, and can have their names placed on the list of those to whom the report is sent annually. Motions to be brought forward at the meeting must be signed by the mover, or by the mover and other Fellows and Members, and must be received by the secretary not later than Nov. 10th.

ASYLUM REPORTS.

Royal Edinburgh Asylum, Morningside (Annual Report for the Year 1912).—At this asylum the average number resident during the year was 756. The total number of admissions was 222, and of the forms of insanity from which patients were suffering melancholia, as usual, was the most prevalent, and accounted for nearly a quarter of the admissions. Among the assigned exciting causes of insanity alcoholic excess still heads the list, but the proportion of cases of "alcoholic insanity" is less than usual. The discharged numbered 129, of whom 58 patients were recovered, the recovery rate being 26 per cent. of the total number of admissions. The total number of deaths was 62 giving a rate of 8·2 per cent. of the average number resident. Sixteen of the deaths were due to general paralysis and 16 were of persons over 70 years of age. There were only six deaths due to phthisis. Dr. George M. Robertson, the physician-superintendent, finds as a new experience that the proper treatment of his patients is hampered by political questions. During the last 18 months he has found on several occasions the friends of patients, as a result of what has appeared in the press on the subject, offering resistance to the necessary humane procedure of the artificial feeding of their relatives. He has even met those who are prepared to allow the patient to starve and probably die rather than be fed. It has been a source of perplexity and astonishment to learn that artificial feeding by means of a tube should be regarded as torture or dangerous. Dr. Robertson has performed the operation over 2000 times, and has never seen evil results in any of the cases. Patients have been fed in hospitals in this way for years at a time. A case of pellagra is quoted as having been admitted to the asylum, and appears to have been the only example of undoubted pellagra that had occurred in the country in the course of 45 years. On July 9th of this year the asylum celebrated the centenary of its opening.

The Retreat, York (Annual Report for the Year 1912).—At this hospital the total number of cases under treatment during the year was 229 certified patients and 31 voluntary boarders. The admissions numbered 57 certified patients and 26 voluntary boarders. One woman admitted was 90 years of age. Thirty-six cases were discharged, and of these 16 were recovered. One of the women discharged recovered had been on the books of the hospital for 12 years. She had suffered from repeated attacks of acute mental disturbance of a severe character and was looked upon as permanently unstable. Twelve patients died during the year, of whom nine were over 65 years of age. With reference to the treatment of incipient insanity, Dr. Bedford Pierce points out that although Bills to provide for the treatment of early undeveloped cases have several times been introduced, nothing has been done. At present there are few, if any, facilities for the proper treatment of either rich or poor until the patient is decidedly insane. Everyone who sees many of these cases deplores the fact that if effective treatment is to be adopted it must frequently be carried out in defiance of the law. It is obvious that all persons with recent, and perhaps temporary, mental disturbance should not be certified as insane, and yet it is illegal for any person to receive such a case into his house for payment. It is, therefore, urgently necessary to amend the law, so that such recent and undeveloped cases can be treated under proper conditions. For the poor the question is even more urgent than for the rich, as no treatment whatever, whether legal or illegal, is available for those unable to pay for early treatment. They are refused admission as voluntary boarders at our public asylums, they are not received at our general hospitals, and nothing can be done until they are ill enough to be taken by the relieving officer before a magistrate and certified as insane.

Asylum of the County Borough of West Ham (Annual Report for the Year 1912).—The total number under treatment at this asylum during the year was 1203, the average daily number on the registers being 927. The total number of cases admitted was 300. The increase in the number of admissions for 1912 was the largest for the last ten years. The proportion per 10,000 of the West Ham pauper insane has risen from 26·5 in 1901 by gradual increments to 37·88 in 1912. Forty of the admissions suffered from forms of mania and 74 from melancholia. Twenty-four were cases of dementia, 38 of general paralysis, and 21 of epilepsy. A large proportion of the direct admissions were, from the point of view of mental recovery, hopeless cases. Out of 279 direct admissions, 110 cases had a hereditary history of insanity, epilepsy, alcoholism, or other neuroses, giving a percentage of 39. These include 70 cases in which no information could be obtained, and many others with scanty and unreliable histories. Fifty-seven cases were discharged recovered, giving a percentage of 20·43 on the direct admissions. The deaths numbered 88, giving a percentage of 9·49 on the average number resident. General paralysis was the cause of death in 24 per cent. of the cases, and senile decay in 21·5 per cent. It appears that the asylum is still overcrowded, but plans for extensions to accommodate 140 males and 240 females have in principle been approved by the Commissioners in Lunacy.

Surrey County Lunatic Asylum at Netherne (Annual Report for the Year 1912).—The average number resident at this asylum during the year was 916, the total number of cases under care having been 1158. The total number of cases admitted during the year was 261, and of these 40 were suffering from congenital mental defect, 12 from epilepsy, 10 from general paralysis, 25 from senile dementia, and in 34 per cent. ultimate recovery could not be reasonably anticipated. The chief causes assigned were: hereditary predisposition, 13 per cent.; alcohol, 4·5 per cent.; worry and mental distress, 4·9 per cent.; and senile decay 12·2 per cent. The recoveries were 87 in number, being 46·2 per cent., calculated on the direct admissions. The deaths numbered 67, giving a rate on the average number resident of 7·32. According to the Commissioners' report the acute hospital is still used for the accommodation of male working patients, the female portion of it being unoccupied. The Commissioners hope that it will before long be devoted to the purpose for which it was provided—that is, for the reception of all new cases, which should be removed to the main building only when the prospect of early recovery has passed.

Staffordshire County Mental Hospital at Cheddleton (Annual Report for the Year 1912).—The total number of cases under treatment at this asylum during 1912 was 1254, the average daily number on the registers being 1034. The admissions numbered 223, and were 38 fewer than in 1911. Heredity appears as a cause in 114 cases, as against 169 cases in the previous year. There were 105 cases discharged, and of these 79 were recovered, the percentage of total recoveries on the direct admissions being 36·28. The deaths numbered 116, giving a percentage on the average daily number on the registers of 11·22. In quite a number of the post-mortem examinations from other causes of death, extensive healed tuberculosis, diagnosed in former years, was disclosed; and these cases, although advanced and extensive when discovered, had apparently been cured by open-air treatment. There was a large diminution in the number of dysentery patients, there having been 37 as against 79 in 1911.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns, with populations exceeding 50,000 persons at the last Census and whose aggregate population at the middle of this year is estimated at 17,852,766 persons, 8209 births and 4888 deaths were registered during the week ended Saturday, Oct. 11th. The annual rate of mortality in these towns, which had been 14·3, 14·4, and 13·6 per 1000 in the three preceding weeks, rose to 14·3 per 1000 in the week under notice. During the thirteen weeks of last quarter the mean annual death-rate in these towns averaged 12·7, against a corresponding rate of 11·8 per 1000 in the Metropolis. Among the several towns the death-rate last week ranged from 2·2 in Southend-on-Sea, 3·6 in Ilford, 6·3 in Walthamstow, 6·4 in Reading and in Cambridge, and 6·8 in Edmonton, to 19·5 in Wigan and in West Hartlepool, 19·8 in Oldham, 20·2 in Bootle, 21·7 in Middlesbrough and in South Shields, and 22·0 in Bury.

The 4888 deaths from all causes were 237 above the number in the previous week, and included 925 which were referred to the principal epidemic diseases, against numbers steadily declining from 1242 to 866 in the four preceding weeks. Of these 925 deaths, 769 resulted from infantile diarrhœal diseases, 44 from diphtheria, 39 from whooping-cough, 26 from measles, 24 from enteric fever, and 23 from scarlet fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 2·7, against 3·2 and 2·5 per 1000 in the two preceding weeks. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had declined from 1104 to 730 in the four preceding weeks, increased to 769 last week; of this number 168 deaths occurred in London, 52 in Liverpool, 44 in Birmingham, 30 in Hull, 28 in West Ham, 27 in Manchester, 26 in Sheffield, and 18 in Preston. The deaths referred to diphtheria, which had been 40, 38, and 43 in the three preceding weeks, were 44 last week, and included 12 in London, 3 each in Birmingham, Liverpool, and Manchester, and 2 each in Portsmouth, Devonport, Stoke-on-Trent, and Leeds. The fatal cases of whooping-cough, which had been 44, 49, and 32 in the three preceding weeks, rose to 39 last week; 9 deaths were registered in London, 4 in Birmingham, 3 in Liverpool, 3 in Newcastle-on-Tyne, and 2 each in Stoke-on-Trent, Manchester, and Sheffield. The deaths attributed to measles, which had been 20, 31, and 28 in the three preceding weeks, further declined to 26 last week, and included 4 in Stoke-on-Trent, 3 in Stockport, and 2 each in West Bromwich, Oldham, and Barnsley. The deaths referred to enteric fever, which had increased from 10 to 19 in the four preceding weeks, further rose to 24 last week; this was the highest number of deaths recorded from this disease in any week of the current year, and included 4 in Manchester, 4 in Hull, 3 in London, and 2 in Portsmouth. The fatal cases of scarlet fever, which had been 18, 19, and 14 in the three preceding weeks, rose to 23 last week, of which 5 were recorded in Birmingham, 4 in Manchester, and 3 in London.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had steadily increased from 2112 to 2817 in the five preceding weeks, had further risen to 3021 on Saturday last; 484 new cases were admitted during the week, against 473, 508, and 498 in the three preceding weeks. These hospitals also contained on Saturday last 1047 cases of diphtheria, 184 of whooping-cough, 63 of enteric fever, and 55 of measles, but not one of small-pox. The 1231 deaths from all causes in London were 139 in excess of the number in the previous week, and were equal to an annual death-rate of 14·2 per 1000. The deaths referred to diseases of the respiratory system, which had been 125, 134, and 124 in the three preceding weeks, rose to 176 last week, but were 106 below the number recorded in the corresponding week of last year.

Of the 4888 deaths from all causes in the 96 towns, 170 resulted from various forms of violence and 358 were the subject of coroners' inquests. The causes of 34, or 0·7 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Sheffield, Leeds, Bristol, Bradford, Nottingham, and in 54 other smaller towns. Of the 34 uncertified causes of death, 6 were registered in Liverpool, 5 in Birmingham, and 2 each in Stoke-on-Trent, Blackpool, and Hull.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns, with an aggregate population estimated at 2,259,600 persons at the middle of this year, 1107 births and 638 deaths were registered during the week ended Saturday, Oct. 11th. The annual rate of mortality in these towns, which had been 14·4, 15 1, and 14·5 per 1000 in the three preceding weeks, rose to 14·7 per 1000 in the week under notice. During the thirteen weeks of last quarter the mean annual death-rate in these towns averaged 14·3, against 12·7 per 1000 in the 96 large English towns. Among the several Scotch towns the death-rate last week ranged from 7·5 in Kilmarnock, 7·6 in Ayr, and 12·1 in Edinburgh, to 19·3 in Perth, 19·5 in Greenock, and 20 4 in Coatbridge.

The 638 deaths from all causes were 11 in excess of the number in the previous week, and included 81 which were referred to the principal epidemic diseases, against numbers declining from 126 to 81 in the four preceding weeks. Of these 81 deaths, 43 resulted from infantile diarrhœal diseases, 14 from measles, 13 from diphtheria, 6 from scarlet fever, 3 from whooping-cough, and 2 from enteric fever, but not one from small-pox. These 81 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·9, against 2 7 per 1000 in the 96 large English towns. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had declined from 96 to 43 in the four preceding weeks, were again 43 last week, and included 15 in Glasgow, 9 in Dundee, 4 in Edinburgh, and 3 in Paisley. The deaths referred to measles, which had been 9, 10, and 8 in the three preceding weeks, rose to 14 last week; 10 deaths occurred in Glasgow and 2 in Edinburgh. The fatal cases of diphtheria, which had steadily risen from 5 to 14 in the six preceding weeks, were 13 last week, of which 4 were registered in Glasgow, 3 in Aberdeen, and 2 in Edinburgh. The 6 deaths attributed to scarlet fever, comprising 3 in Aberdeen, 2 in Glasgow, and 1 in Motherwell, were equal to the average in the six preceding weeks. The deaths referred to whooping-cough, which had been 9, 6, and 5 in the three preceding weeks, further declined to 3 last week, of which 2 occurred in Glasgow and 1 in Paisley. The 2 fatal cases of enteric fever were recorded in Edinburgh and Leith respectively.

The deaths referred to diseases of the respiratory system, which had been 63, 66, and 69 in the three preceding weeks, further rose to 84 last week; 23 deaths were attributed to different forms of violence, against 26 and 27 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,199,180 persons at the middle of this year, 560 births and 394 deaths were registered during the week ended Saturday, Oct. 11th. The annual rate of mortality in these towns, which had been 19·8, 21·0, and 18·0 per 1000 in the three preceding weeks, further declined to 17·1 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these Irish towns averaged 18·2 per 1000; in the 96 large English towns the corresponding rate did not exceed 12·7, while in the 16 Scotch towns it was equal to 14·3 per 1000. The annual death-rate last week was equal to 18·9 in Dublin (against 14·2 in London and 14·9 in Glasgow), 16 7 in Belfast, 24·5 in Cork, 7·6 in Londonderry, 12 2 in Limerick, and 15 2 in Waterford, while in the remaining 21 smaller towns the mean death-rate did not exceed 14·9 per 1000.

The 394 deaths from all causes were 21 fewer than the number in the previous week, and included 68 which were referred to the principal epidemic diseases, against numbers declining from 132 to 94 in the four preceding weeks. Of these 68 deaths, 55 resulted from infantile diarrhœal diseases, 4 from diphtheria, 3 from enteric fever, 3 from whooping-cough, 2 from scarlet fever, and 1 from measles, but not one from small-pox. The mean annual death-rate

from these diseases last week was equal to 3·0 per 1000; in the 96 large English towns the corresponding rate was 2·7, while in the 16 Scotch towns it did not exceed 1·9 per 1000. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had steadily declined from 111 to 78 in the four preceding weeks, further fell to 55 last week; of this number 29 occurred in Dublin, 9 in Belfast, 4 in Cork, and 3 in Clonmel. The deaths referred to diphtheria, which had been 4, 1, and 3 in the three preceding weeks, were 4 last week, and comprised 2 in Dublin and 2 in Belfast. The 3 fatal cases of enteric fever, which were equal to the number recorded in the previous week, were recorded in Dublin, Belfast, and Clonmel respectively. The 3 deaths attributed to whooping-cough were slightly below the average in recent weeks, and were recorded in Dublin, Galway, and Bangor respectively. The fatal cases of scarlet fever were registered in Dublin and Belfast, and that of measles in Dublin.

The deaths referred to diseases of the respiratory system, which had been 56, 60, and 34 in the three preceding weeks, rose to 54 in the week under notice. Of the 394 deaths from all causes, 122, or 31 per cent., occurred in public institutions, and 4 resulted from various forms of violence. The causes of 14, or 3·6 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 96 large English towns the proportion of uncertified causes of death last week did not exceed 0·7 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Order in Council of April 1st, 1881, Fleet-Surgeon Henry Edward Tomlinson has been placed on the Retired List at his own request (dated Oct. 14th, 1913).

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Reginald J. C. Cottell is placed on retired pay (dated Oct. 13th, 1913).

Major Gerard W. Tate to be Lieutenant-Colonel, vice J. Richie, deceased (dated Oct. 7th, 1913).

Colonel G. D. Hunter, D.S.O., has embarked for a tour of service in India. Colonel J. Maher has been selected for appointment as Assistant Director of Medical Services to the Gibraltar Command.

Lieutenant-Colonel J. S. Davidson, in charge of the Military Hospital at Agra, has been selected for the increased rate of pay under Article 358 of the Royal Warrant for Pay and Promotion. Lieutenant-Colonel J. H. Daly has been transferred from Limerick to the Belfast District and appointed Senior Medical Officer to the North Irish Coast Defences. Lieutenant-Colonel F. P. Nichols has been appointed to hold charge of the Military Hospital at Taunton. Brevet-Colonel and Lieutenant-Colonel C. H. Melville has been permitted to transfer (by exchange) to the Home Establishment, vice Lieutenant-Colonel J. M. F. Shine, appointed for a tour of service in India. Lieutenant-Colonel W. C. Beevor, C.M.G., has been selected for appointment as Deputy Assistant Director of Medical Services to the North Midland Division. Lieutenant-Colonel O. R. A. Julian, C.M.G., has been transferred from the Irish Command to the London District for duty at the Royal Hospital, Chelsea, in succession to Lieutenant-Colonel R. J. C. Cottell. Lieutenant-Colonel G. A. T. Bray has been placed under orders for a tour of service with the Seventh (Meerut) Division of the Northern Army in India.

Major S. L. Cummins has been selected for appointment as Assistant Professor of Pathology at the Royal Army Medical College. Major J. V. Forrest has arrived home on leave of absence from Khartoum. Major J. D. Alexander has been appointed for duty at the Military Hospital, Calcutta. Major R. L. Argles has been appointed for service in India. Major E. V. Aylen has taken up duty at Gharial. Major E. H. Condon has been placed under orders to embark for a tour of service with the Seventh (Meerut) Division of the Northern Army in India. Major B. B Burke has been appointed to the Eastern Command for duty. Major G. St. C. Thom has been appointed for duty on board the transport s.s. *Rewa*, which left Bombay for Southampton with tour-expired troops on Oct. 10th. Major H. J. M. Buist, D.S.O., commanding No. 23 Company of the Royal Army Medical Corps at Roberts' Heights, Pretoria, has been selected for advancement to the rank of Lieutenant-Colonel, in succession to Lieutenant-Colonel O. L. Robinson, supernumerary. Major J. G. Churton has taken up duty as Specialist in Operative Surgery at the Military Hospital, Bangalore Cantonment. Major E. G. Ffrench has been appointed to hold charge of the Military Hospital at Poonamallee Cantonment, Madras Presidency. Major W. P. Gwynn, on expiration of leave of absence home from Shwebo, Upper Burma, has been appointed to the Irish Command. Major S. W. Sweetnam has been transferred from the Indian to the Home Establishment.

Captain W. F. Ellis has been selected for appointment as Specialist in Operative Surgery to the Cambridge Hospital at Aldershot. Captain W. B. Purdon has joined at Belfast. Captain G. S. Wallace has embarked for a tour of service with the Ninth (Secunderabad) Division of the Southern Army in India. Captain F. L. Bradish has been appointed to the Dublin District. Captain W. M. MacDowall has been placed under orders to embark for a tour of service in the Sierra Leone Protectorate. Captain G. F. Rudkin has taken up duty in the Dublin District. Captain J. R. Foster has been granted six months' leave of absence home from India with permission to revert to the Home Establishment at its conclusion. Captain D. S. B. Thomson has arrived home on leave of absence from duty with the Egyptian Army. Captain J. McKenzie has been placed under orders for a tour of duty with the Eighth (Lucknow) Division of the Northern Army in India, embarking Oct. 22nd. Captain O. C. P. Cooke has been appointed to the Cork District. Captain A. S. Cane has been selected for appointment as Specialist in Dermatology and Venereal Diseases at the Military Hospital, Poona Cantonment. Captain H. O. M. Beadnell has taken up duty at the Military Hospital, Tidworth, Salisbury Plain. Captain D. Coutts has been transferred from Ranikhet Cantonment to the Military Hospital at Agra. Captain D. Ahern has been appointed medical officer in charge of Abbassia, Cairo. Captain C. A. T. Conyngham has been appointed Specialist in Dermatology and Venereal Diseases at Mhow. Captain J. R. Foster has arrived home on leave of absence from the Military Hospital at Neemuch Cantonment. Captain K. A. C. Dorg has been placed under orders for a tour of duty with the Seventh (Meerut) Division of the Northern Army in India. Captain B. Johnston has taken up duty in the Cork District. Captain J. M. B. Rahilly has taken up duty at the Military Hospital, Shorncliffe. Captain M. P. Leahy has been transferred from the Dublin District to Maryborough Head. Captain J. G. Bell has embarked for a tour of service in the Straits Settlements. Captain A. C. Amy has been granted six months' leave of absence home from India, reverting to Home Establishment at its expiration. Captain J. du P. Langrishe has arrived home on leave of absence from the Military Hospital at Kirkee Cantonment. Captain T. S. Dudding has been placed under orders to embark for India for duty with the Sixth (Poona) Division of the Southern Army. Captain W. G. Maydon has taken up duty at the Military Hospital, Glasgow. Captain A. M. Pollard has arrived home for duty from South Africa. Captain H. Gall has been transferred from the Military Hospital at Sialkot Cantonment to Khyra Gali, Murree Hills District. Captain T. E. Harty has embarked for a tour of service in the Sierra Leone Protectorate.

Lieutenant R. W. Vint has been placed under orders to embark for a tour of service with the Northern Army in India. Lieutenant W. Bissett has been appointed to hold charge of the Cantonment General Hospital at Dagshai Cantonment. Lieutenant O. W. J. Wynne has embarked for a tour of service in India.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel C. Duer has been granted an extension of leave of absence home from India. Lieutenant-Colonel P. Carr-White has been appointed Agency Surgeon to the Kotah and Jhalawar States on return to duty from leave of absence. The services of Lieutenant-Colonel T. E. Dyson have been placed temporarily at the disposal of the Government of India.

Major C. A. Lane, Civil Surgeon at Murshidabad, has been

transferred to Darjeeling and appointed to officiate as Civil Surgeon during the absence on sick leave of Major J. Gwyther. Major H. B. Foster has taken up duty at Calcutta. Major N. P. O'Gorman Lalor has arrived home on leave of absence from India. Major J. C. Robertson has been appointed Sanitary Commissioner at Delhi. Major J. H. McDonald has been granted six months' extension of leave of absence home from India on medical certificate. Major L. J. M. Deas, Agency Surgeon to the Bhopawar State, has been appointed to officiate as Political Agent during the absence on leave of Lieutenant-Colonel B. E. M. Gurdon, C.I.E., D.S.O. Major V. H. Roberts, Civil Surgeon at Seoni, has been appointed to hold medical charge of the Chhindwara District during the absence of Captain W. J. Fraser on special duty at the Central Research Institute, Kasauli Cantonment. Major W. F. Harvey has taken up duty as Director of the Central Research Institute at Kasauli Cantonment in succession to Sir David Semple, R.A.M.C., who has relinquished the appointment.

Captain N. M. Wilson, on return to India from leave of absence home, has been appointed to officiate as Civil Surgeon at Dera Ghazi Khan. Captain R. H. Bott has been appointed to officiate as Professor of Surgery at the Government Medical College, Lahore, during the absence on leave of Lieutenant-Colonel E. V. Hugo. Captain A. S. M. Peebles, superintendent of the Central Lunatic Asylum at Berhampore, has been appointed to officiate as Civil Surgeon of Murshidabad during the absence on deputation of Major C. A. Lane. The services of Captain R. S. Kennedy have been replaced at the disposal of the Government of India. Captain A. C. Ingram has been granted leave of absence home from India for one year and eight months. Captain M. J. Quirke has been appointed to officiate as Sanitary Commissioner to the Madras Presidency during the leave of absence of Captain M. A. Justice. Captain G. A. Jolly has been transferred fram Mainpuri and appointed Civil Surgeon at Fategarh. Captain H. S. Hutchison has been appointed to officiate as Deputy Sanitary Commissioner of the Central Registration District in Bombay during the absence on special duty of Lieutenant-Colonel T. E. Dyson. Captain J. H. Horton, D.S.O., has been appointed Civil Surgeon at Sukkur during the absence on leave of Major C. R. Bakhle.

SPECIAL RESERVE OF OFFICERS.

Lieutenant George F. Randall to be Captain (dated Sept. 19th, 1913). Lieutenant Charles J. Simpson resigns his commission (dated Oct. 15th, 1913). Lieutenant Henry P. Crow is confirmed in his rank.

TERRITORIAL FORCE.

Royal Army Medical Corps.

1st Welsh Field Ambulance, Royal Army Medical Corps: Lieutenant Edmund V. Connellan to be Captain (dated August 1st, 1913).

2nd Welsh Field Ambulance, Royal Army Medical Corps: Lieutenant John S. Rowlands resigns his commission (dated October 11th, 1913).

Attached to Units other than Medical Units.—Lieutenant Lewis Beesly to be Captain (dated June 1st, 1913). Lieutenant-Colonel William Wilson resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform (dated October 11th, 1913).

For attachment to Units other than Medical Units.—Sidney Scott (late Second Lieutenant, 4th Northumbrian (County of Durham) (Howitzer) Brigade, Royal Field Artillery), to be Lieutenant (dated October 11th, 1913).

DEATHS IN THE SERVICES.

Lieutenant-Colonel John Ritchie, R.A.M.C., on Oct. 6th in Glasgow in his fifty-second year. He entered the service in 1887, and in 1898 went out to West Africa. He was present at the operations in Sierra Leone, 1898–9 (medal with clasp), and during the South African war took part in the operations in the Orange River Free State in 1900, and later in the operations in the Transvaal, including the actions near Johannesburg, Pretoria, and Diamond Hill. He was also engaged in the operations in the Orange River Colony, including the actions at Wittebergen, and in Cape Colony, south of Orange River (Queen's medal with four clasps and the King's medal with two clasps).

Major Herbert Cumming French, R.A.M.C., in his 44th year. With previous service he became Surgeon-Lieutenant in 1893 and attained the rank of Major in 1905. He served in the South African war and took part in the operations in the Transvaal and in the Orange River Colony 1901–02 (Queen's medal and two clasps). He was specialist in dermatology at Cairo in 1904, at Woolwich in 1905–06, and at Malta in 1909.

MEDICAL PRACTICE UNDER THE INSURANCE ACT.

(BY OUR SPECIAL COMMISSIONER.)

(*Continued from p. 1024.*)

XXIII.—NEWCASTLE: EARLY ORGANISATION OF MEDICAL UNIONS AND THEIR DECAY.

AT Newcastle I found much dissatisfaction still prevalent as to the manner in which the resistance to the National Insurance Act had been conducted, and in regard to the attempts to amend the Insurance Act the same feeling was expressed. It must be borne in mind that both in Northumberland and Durham the medical profession has been organised for some time, so that failure was not expected. Many strikes have taken place, and on the whole the medical unions in these contests came off victorious. Since the autumn of 1900 the work of organisation had been particularly active, and, indeed, I have described at length some of the achievements of the Northumberland and Newcastle Medical Association, and other bodies like the Newcastle Medical Ethical Society and the Northumberland and Durham Medical Union.[1] One of the chief of these achievements was the raising in most of the colliery districts of the sums paid to the colliery surgeons by no less than 50 per cent. Formerly the collier paid 6*d.* a fortnight for medical attendance on himself and his family, and this was raised to 9*d.* Then the war against imported medical men proved very effective, a black list was rigorously kept, and the coöperation of consultants was obtained. The different bodies, some of whom afterwards coalesced, were well disciplined fighting bodies, and their union was not merely a name but a reality, for they fought and won many a battle. To-day, however, what remains of these organisations has lost much of its old vigour with loss of individuality. This, perhaps, was inevitable. The British Medical Association, which under its new constitution absorbed these Northern medical leagues, was expected to strengthen the influence of the local unions, while it was said that expense would be saved for those members who belonged to their local union as well as to the British Medical Association. It was agreed that the organisation of the unions should be maintained under the name of a committee, the Durham Committee and the Newcastle Committee of the British Medical Association. This amalgamation was effected some three years before the National Insurance Bill was discussed, and did not work harmoniously. Nothing will be gained now by raking up old grievances; it suffices to say that at one time there were acute differences of opinion in Newcastle on the subject of united action in regard to the National Insurance Bill, but when the offer of 8*s.* 6*d.* was made public it was soon quite clear that resistance would no longer be possible. Professor Rutherford Morison and many others still think it would have been wiser to have accepted under protest this offer instead of exhibiting the weakness of the organisation of the profession by an abortive attempt at resistance. Nearly all the general practitioners went on the panel.

The Insurance Committee's Work.

The population of Newcastle is 266,603, according to the last Census, and the Insurance Committee has the record of 87,000 insured persons. There are 110 practitioners on the panel, though a few of them are not actually residing in Newcastle, but practise in the suburbs. The panel doctors were promptly paid on April 15th, the very day the money was due, the full 1*s.* 9*d.* per person insured for their first quarter's

[1] See THE LANCET of Feb. 23rd and April 6th, 1901, and Nov. 15th and 22nd, 1902.

work. The same business-like regularity occurred again on July 1st, 1913. There remains a very large number, more than 8000, of insured persons who have not yet selected a medical attendant. The money that these persons have paid was divided equally among all the panel doctors. But it is now proposed to allocate these insured persons, giving a larger number to the panel doctors who have the shortest lists. One panel doctor has about 3500 names on his list, and there are a few who have over 2000, but this is exceptional. The great majority of panel doctors are responsible for less than 2000 insured persons. The clerk of the Insurance Committee thinks that the Act is working well, and the fact that there has been no meeting of the medical subcommittee to sit and judge whether complaints made as to medical attendance are well founded or not is in itself evidence to the same effect. The dispensing chemists have been paid 85 per cent. on their claims. Their bills have exceeded the 1*s.* 6*d.*, but when the floating 6*d.* is added they have not overstepped the 2*s.* During the better season of the year the small deficit may be met. In the meanwhile, it is very certain that more medicine has been consumed than was ever the case before. If, therefore, drugs are of real service, the inhabitants of Newcastle should now be in the enjoyment of better health than formerly. Of course, some allowance must be made for the presence of malingering, of which complaint is made here as elsewhere. A scheme is being considered to create a medical committee whose business it should be to investigate suspected cases of malingering, and the proposal is that the panel doctors should sit in rotation on this committee, so as not to deal with their own cases. But, on the other hand, the objection can be made that the detection of malingering is a specialty in itself, and every doctor is not equally competent. The fact recently announced that the Government is now attending to the matter has, however, checked to some extent local efforts. Already two new committees are to be brought into existence in accordance with the recent amendments to the Act, one to represent exclusively the panel doctors and the other the dispensing chemists. As yet I have heard no complaints against this procedure. As long as the general Medical Committee representing all the members of the profession in the area remains intact, there seems to be no objection to the formation of minor committees to attend to special matters concerning individually the members of such committees and those who nominate them. However, these supplementary committees are not necessarily to be formed at once, so it is somewhat early to criticise.

Inadequate Tuberculosis Dispensary.

By far the most urgent matter at Newcastle at the present moment is to obtain suitable premises for the tuberculosis dispensary. This institution is for the moment situated close to the town hall. It is very accessible, but the street is so noisy that it is difficult to examine the patients. Then the dispensary only consists of two small rooms or compartments. One of these is the clerk's room, the store-room, the writing-room, and the waiting-room, all in one. The other is the consulting-room, the bacteriological laboratory, and the patients' dressing-room, also all in one. An enormous amount of time is lost by the medical officer, who has to wait till one patient has resumed his clothes before another patient can be admitted into the room. But it appears that when efforts have been made to rent larger and more suitable premises the people living near have raised objections against so many consumptive patients coming daily into their neighbourhood. This institution works partly for the health authorities and partly for the Insurance Committee. If an insured person has phthisis and applies for sanatorium benefit he is referred to the physician in charge of the tuberculosis dispensary, and the latter advises as to the treatment which should be adopted; in the majority of cases this is domiciliary. When a patient returns from a sanatorium he is expected to attend at the dispensary, and here his progress will be watched and tuberculin treatment can be given. The Insurance Committee in these cases pays 7½*d.* to the town, and the latter pays the physician who attends at the tuberculosis dispensary. Then the town undertakes to provide 120 beds, but of these only 80 are actually ready for patients. This tentative measure is probably right, for if a large hospital was built a prejudice might arise against the place, and patients might refuse to go there, for there are no compulsory powers. However, there is one good feature already manifest in the attitude of the people at Newcastle. The idea of early treatment is becoming more and more popular. Also confidence has grown as to the discretion observed at the dispensary. Nothing is ever said except in regard to children attending school, so that adults coming for advice are not afraid of losing their employment. Thus persons who are in doubt now come freely to be examined at the tuberculosis dispensary, and therefore it is all the more necessary that proper premises should be secured.

Where the Wage Limit is Needed.

In Newcastle the panel doctors working in the industrial districts are well satisfied with results. In neighbourhoods such as Heaton they can get their visiting done with ease and promptitude owing to the fact that the ceremonies of social calling are not required of them. But in the West-end the position is different. Here we have a population of clerks and persons of moderate incomes who are employed in trade or commerce. They live in small, well-kept, self-contained houses, and many keep a servant. When the panel doctor calls he cannot open the street door, announce himself, and walk straight in. He must ring the bell, wait perhaps while the servant girl puts on a clean apron before she opens the door. Then instead of seeing the patient at once he is introduced into a small parlour, where he lingers till the patient is apprised of the visit and has had his bedclothes straightened out a little. Altogether, the doctor finds that the visits to his contract patients absorb as much of his professional time as those to his private patients. This class of patient has been accustomed to pay the fees—low fees, of course—to their medical attendants; and the fact that to-day they are insured persons makes no difference to their domestic arrangements. Their front doors remain shut, and the doctor, whether on the panel or not, must ring the bell to gain admittance. Among the colliers living side by side in a row of little cottages, with their front doors open, it would be possible, though not desirable as a routine, to make 20, even 25, visits in an hour. At Newcastle, in such districts as Heaton, perhaps 15 visits may be made in the hour, but in the West-end three, four, or five visits is the most that can be done in that time. Yet in all these cases the remuneration under the contract system is exactly the same. So enormous is the difference and the loss it entails on the West-end practitioners that three of them have resigned their position on the panel. Here more than in any locality which I have yet visited has the necessity for establishing a wage limit seemed clearest to me. It is said, however, that it is not worth while taking the great amount of trouble this would entail, for there are so very few insured persons whose income is above £104 a year and under £160. That is doubless true; but if their number be small in comparison with a total of some 14,000,000 insured persons, they cluster together, and in certain districts they constitute perhaps the large majority of the inhabitants. Thus, if the medical profession as a whole does not suffer much for the want of a wage limit its absence means grave loss for individual practitioners living in the districts where this class of insured persons habitually resides.

One practitioner in the West-end, who had about 1200 insured persons on his list, told me that his private practice among people whose income exceeded £160 amounted to 20 per cent. of the whole practice. The remaining 80 per cent. were all insured persons, and of these only 32 per cent. were earning less than £2 a week, while 48 per cent. received more than £2 a week, though apparently less than £160 a year. A wage limit would therefore restore to him as private patients, paying full fees, 48 out of every 80 insured persons. Instead of a practice with only 20 per cent. of private patients and 80 per cent. of contract patients the wage limit would give him a practice of 68 per cent. of private patients and only 32 per cent. of contract patients. After giving me these details my informant expressed the opinion that if the profession had made a firm stand in November, 1912, the wage limit could have been introduced into the Bill. In Newcastle the medical profession has continued to feel keenly on this point, and it was frequently mentioned to me. The Newcastle Insurance Committee, however, instead of deciding last January whether they would establish a wage limit, put the matter off for three months. Then the committee would not at once discuss the matter, but wanted the panel doctors

to sign the engagement first that they would continue their service for the remaining nine months of this year. Thereupon four West-end doctors resigned, and after that, in the absence of those who were most interested in the matter, it was easy for the committee to decide that nothing could be done in regard to a wage limit. At a meeting of the Newcastle Trades Council the question of a wage limit was also discussed, and one of the trade union representatives said "he would not think of consulting a panel doctor." If there are many insured persons in Newcastle who have not selected their panel doctor this is not due in the main to negligence, but to the fact that many members of the public do not care to be attended under the contract system. Thus they have, as it were, voluntarily imposed on themselves a wage limit, since they will pay fees and refuse the service of their panel doctor. Consequently the practitioners who have refused to go on the panel are benefiting, particularly as they are not numerous. It will be seen, therefore, that in Newcastle medical men, consulting merely their pockets, would not be unanimous in their views of the Act. For some it has meant prosperity; some have been hard hit by it.

The Colliery Surgeons and the 9d.

Though there are only two coalpits in the district Newcastle is nevertheless a great coal-trade centre, and it is from Newcastle that the colliery surgeons were helped to organise their unions. It has been explained how these unions succeeded in raising the pay from 6*d*. to 9*d*. per fortnight per family, but this has been upset by the Insurance Act, and a new arrangement is still a matter of dispute. Now that those who work in the pits are insured persons the pitman as the head of a family refuses to pay the 9*d*. per fortnight, since he is also paying for his own insurance separately and under the Act. A colliery surgeons' committee does exist, but it is not easy to discover what it has done. The colliery surgeons, for the most part, have been left to fight their own battle, and in their isolated, disorganised condition not a few have had to relapse into the old terms of 6*d*. per fortnight for attending the non-insured members of a collier's family. Undoubtedly, all the colliery surgeons should have been convoked so as to agree on the terms they would one and all ask. Seeing that insured members of each family contribute separately, it is quite natural that the colliers should expect to pay a little less for their families. If the surgeons had unanimously offered to accept 8*d*. instead of 9*d*. the probabilities are that this would have been generally accepted. A great number of colliery surgeons, however, insisted on maintaining the 9*d*. Though they would have fewer patients, they argued that the giving of certificates would entail more trouble. Then there is the question of the boys, on whom there is undoubtedly a dead loss. Before the Act, when a boy reached the age of 16 and descended into the pit to work, he paid 6*d*. per fortnight for medical attendance, and in some districts he even paid the full 9*d*. per fortnight. At the lower figure this meant 13*s*. for the colliery surgeon. Now, and under the Act, the doctor only receives 7*s*. Under the old system the fact that youths paid more than their share, if judged by the amount of trouble they gave, served to compensate the fact that the payments made for the women and children were insufficient. Also, before the Act if a certificate was required the colliery surgeon charged a shilling for it; now under the Act no charge can be made for the certificates when required by insured persons. Thus a youth brings in 7*s*. per annum instead of 13*s*. and has certificates for nothing instead of paying a shilling for each. Then there is a new difficulty in regard to collecting the money from non-insured persons. When there was but one payment effected, and that was by the chief wage-earner, the colliery owner deducted the amount from the wages and handed it over to the colliery surgeon. This prevented bad debts and simplified matters. But to-day it is for the women and children that the money has to be collected, and the colliery owners know nothing about them. Also the money when collected has to be paid, not to one colliery surgeon, but to different panel doctors. This the cashiers at the collieries object to do. It is not their business, and if they undertook such work they would expect a commission of 5 to 10 per cent. on the money handled. Thus it comes about that many colliery surgeons insist on the 9*d*. as before the Act, though they will have a smaller number of persons to attend. But in several places where this stand has been made doctors have come in from outside offering to do all that is required for 6*d*. per fortnight. In the olden days, when the unions were well organised and managed, the advent of such practitioners was promptly signalised, and they were so rigorously dealt with that their departure was not long delayed. But the merging of the local well-disciplined and fighting unions into the larger but not so compact British Medical Association renders quick action less easy, and has discouraged many of the local practitioners who formerly fought so well.

(To be continued.)

WALES.

(FROM OUR OWN CORRESPONDENT.)

The Medical Officership of Health of Abertillery.

THE Local Government Board has constantly urged the sanitary authorities in the Monmouthshire colliery districts to appoint whole-time medical officers of health, and in 1906 definitely suggested the combination for that purpose of the urban districts of Abertillery, Nantyglo and Blaina, and Ebbw Vale. The councils of these three districts were not able to come to any agreement on the matter, but about four years ago the Abertillery council appointed, nominally as a whole-time officer, Dr. A. E. Remmet Weaver, who was to hold the joint office of medical officer of health and school medical officer, at a salary of £400 per annum. Subsequently he was paid an additional £10 per annum for acting as medical officer of the school clinic. Of his total salary £250 were allocated as that of medical officer of health, and one-half of this sum came from the Exchequer grants, so that the contribution from the local rates to his salary was £285. In later years further grants were received from the Board of Education, so that latterly the cost to the ratepayers has only been £205 per annum. Dr. Weaver has been appointed medical officer of health for the borough of Yeovil, and the Abertillery council is desirous of continuing to his successor the low salary which he has been receiving. The Local Government Board, however, is pressing for a minimum salary of £500 per annum, which can hardly be considered extravagant for a district with a population of 39,000 persons scattered over a hilly district with an area of ten square miles. There are about 7000 school children, and the medical officer of health is expected to attend at the fever hospital, to take charge of the school clinic, and to carry out the bacteriological examinations necessary. The avowed reason for paying so low a salary is that the local rates are so high. If economies are to be exercised it is hardly prudent to do so by underpaying a responsible official, the results of whose labours cannot always be measured in pounds, shillings, and pence.

The Reduction of Pauperism.

At the North Wales Poor-law Conference recently held in Chester, Mr. Herbert Lewis, Parliamentary Secretary to the Local Government Board, stated in his presidential address that in Wales and Monmouthshire the rate of pauperism was 25 per 1000 of the population, or a reduction of 5 per 1000 in the past four years. In the whole of England and Wales the rate had been reduced in four years from 27 to 22 per 1000. He suggested the desirability of appointing women as relieving officers.

Public Health in the Rhondda Valleys.

The persistent attention that has been given in recent years to the removal of insanitary conditions in the Rhondda urban district is at last bearing fruit, and the vital statistics which the medical officer of health, Dr. J. D. Jenkins, includes in his recently issued annual report for 1912 are of a very satisfactory character when compared with those of former years. The death-rate from all causes in that year was 13·8 per 1000, and the infantile mortality rate was 127 per 1000 births. The latter rate was 26 per 1000 above that recorded during the same period in the 95 great towns of England and Wales, but it is the lowest Rhondda rate yet recorded. Among the most potent factors operating prejudicially to the preservation of infant life in the district, Dr. Jenkins mentions the abnormally high birth-rate, which in 1912 was 33·1 per 1000, the number of

stillbirths, the early age of the mother at marriage, the urban conditions of life, domestic insanitation, housing conditions, and the ignorance and carelessness of mothers. In many north country towns, among the insanitary conditions which are said to increase the number of deaths among young children there is usually included the presence of privy middens or of the accumulation on household premises of house refuse. It is interesting to learn from Dr. Jenkins that water-carriage is practically universal in the Rhondda urban district, for nearly 27,000 houses are provided with water-closets, and at only 146 houses are there privy middens or pail closets. Fixed ashpits are also non-existent, for there is a daily removal of all household refuse, the collection being completed before 1 P.M. each day. The ultimate destination of this refuse is, however, not at all satisfactory. For about ten years and until two years ago a small destructor was in use, but it dealt with quite an inappreciable quantity of the refuse collected, and the greater part was deposited on huge tips in various parts of the district. With the large amount of building that has been going on there has been an increasing difficulty in obtaining sites for this deposit, and dwellings have crept nearer and nearer to the existing tips. There is now to be erected at Porth a modern destructor capable of dealing with about 82 tons of refuse daily, or about one-third of the total amount produced in the whole district. The heat derived from the use of the destructor is to be used by the Electric Power Distribution Company, and if Dr. Jenkins's advice is carried out it will also be available for a steam disinfector to supplement that at the isolation hospital some five miles distant. Among other recommendations made by Dr. Jenkins are the erection of municipal slaughter-houses; the application of provisions contained in the special Acts of Parliament of the district for the control of the milk-supply, with special reference to the spread of infectious disease; and the acquisition of plots of land situated in localities at present unprovided for and suitable for purposes of recreation.

Oct. 14th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh University: the New Chair of Bacteriology.

Professor James Ritchie delivered his inaugural lecture in the McEwan Hall on Oct. 7th, in the presence of a large gathering of students and of the public. Principal Sir William Turner presided, and was accompanied on the platform by a number of professors and lecturers. Professor Ritchie took as his subject the Place of Bacteriology among the Sciences.

Clinical Instruction in Edinburgh Royal Infirmary.

Sir Thomas Fraser, in his opening address to the combined classes of clinical medicine at the Royal Infirmary, which is reported in another column, outlined the new scheme which is now adopted, and which has already been described in THE LANCET. A successor to Professor Greenfield has not yet been appointed, but the joint committee of the University Court and the infirmary managers met on Oct. 11th to recommend a leet of two to the University Court, in order that one of them may be appointed to the Moncrieff Arnott chair of Clinical Medicine. It is understood that the committee selected from the list of applicants for the new chair Dr. William Russell and Dr. Graham Brown. These names will be submitted to the University Court, which will make the appointment.

Scarlet Fever Outbreak in Edinburgh.

There has recently been a considerable outbreak of scarlet fever in the city, with the result that between 20 and 30 cases are under treatment at the city fever hospital. The public health office, acting with commendable celerity, at once traced the milk-supply of the sufferers to its source, with the result that the origin of the disease was discovered, and risk of an epidemic almost certainly averted.

Queen Mary's Nursing Home for Patients of Limited Means, Edinburgh.

The new nursing home, Chalmers-street, Edinburgh, recently opened by Lord Balfour of Burleigh, is intended to bridge the gap between the supply of nursing accommodation and treatment provided for the poorer class in the hospitals and that for the well-to-do given in expensive private homes. It is an extension of a pioneer institution in Rutland-square. At a public meeting in Edinburgh in 1911, under the chairmanship of Sir Robert Usher, Bart., a committee was formed, with Lord Dunedin as chairman, Professor Lodge, chairman of executive, and Dr. D. Chalmers Watson, the initiator, as honorary secretary, to appeal for the sum of £13,500 to defray the cost of building and furnishing, when the home, at the moderate fees it was intended to charge patients, could be made self-supporting. Of that sum over £13,000 have been raised. Three continuous villa residences were purchased in Chalmers-street, and under the supervision of Mr. T. Duncan Rhind, A.R.I.B.A., the interiors were reconstructed to fit them for their new purpose. All cornices and skirting have been eliminated to reduce the lodgment of dust to a minimum. The home, available for both sexes and either medical or surgical treatment, contains about 50 beds; two wards each of 8 beds; five of 3 beds; one of 2 beds; twelve private rooms with 1 bed; and a children's nursery, 4 beds. The charges range from £1 1*s.* to £3 3*s.* per week for maintenance and nursing, the patients also being responsible for the doctor's fee. Her Majesty the Queen, in becoming a Patron, has given permission for the Home to be called by her name. The doors of all rooms have been made wide enough to allow a bed to be easily passed in and out. There are two first-class operating theatres, lighted from the east side and from the roof. The floor and the walls (to the height of 4 feet) are in green and white Terrazzo marble; the upper walls in cement, plaster enamelled. Between the two theatres is a sterilising room. Opening off the hall that conducts to the operating theatres is an anæsthetic-room with side folding doors; there is a store for sterilised instruments. In the basement is a room fitted up with X rays, with a dark room, and a doctor's room adjoining. The nursing staff consists of 16, and the domestic staff of 7, with a porter. The matron and chief officials have been transferred from the Rutland Nursing Home, now incorporated in the new Home.

Free Blood Examinations in Glasgow.

Provision has been made in the Public Health Laboratory of Glasgow for carrying out free of charge to medical men the Wassermann reaction and other tests mentioned in the resolution of the corporation of April 17th. The requisite equipment for collecting the sample to be examined will be supplied on application by medical men, and this should be returned to the medical officer of health with the information requested in the schedule accompanying the equipment. The name of the patient need not be given, but the age, sex, and occupation, together with the leading symptoms present, and the name of the ward of the city in which the patient resides, must be stated. The test should be had recourse to only where external manifestations of specific disease are absent and the symptoms otherwise obscure. A fee of 2*s.* 6*d.* will be paid for each sample of blood forwarded for examination.

Diphtheria in Aberdeen.

The number of cases of diphtheria notified last week in Aberdeen was 92 up to Friday morning. For the same period in the previous week only 60 cases were notified. The cases continue for the most part to be mild, there having been very few deaths so far. Not only is there no sign of abatement of the epidemic, but the number of children affected increases daily. The school water is still cut off, and on the advice of the medical officer of health the children are urged to gargle with a disinfectant three times a day. The teachers are also endeavouring to keep articles such as pen, pencils, &c., from circulating in the classes.

Typhoid Fever in Aberdeen.

The report of Dr. Matthew Hay, medical officer of health, on the typhoid outbreak which occurred in Aberdeen last year has now been laid before the public health committee of the Aberdeen town council. The report is divided into four parts, the first part dealing with the previous history of typhoid fever in Aberdeen, the second part dealing with last year's outbreak, the third with paratyphoid cases, and the fourth giving additional information regarding the persons attacked in the outbreak of typhoid and paratyphoid. With regard to the outbreak in 1912, the report states that

suddenly in the course of October, 1912—after the notification of only 15 cases (including four cases from a foreign ship) in the whole of the preceding nine months, most, if not, all of which had been traced to their sources—54 cases of typhoid (including paratyphoid) were notified or discovered, followed by 43 in November and by eight in December. Only once in the preceding 25 years had the number of cases in any one month exceeded the numbers in October and November, 1912. This was in December, 1898, when there were 61 cases. In the preceding months of that year, September, October, and November, the numbers were 30, 20, and 30 respectively, and in the immediately succeeding month of January, 1899, there were 32 cases, making in all 173 cases in five months. In the two months preceding the outbreak of 1898 the numbers were 5 and 6 respectively, and in the whole first eight months of the year only 38 cases were notified. The two outbreaks, therefore, bear some resemblance to each other. The earlier outbreak Dr. Matthew Hay believes to have originated in milk infection. The report goes on to describe how the search for possible sources of infection of the 1912 outbreak led to a creamery, and on from there to a farm—the only one—which sent part of its milk to the creamery and part into Aberdeen.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Labour Trouble in Dublin.

THE labour dispute in Dublin cannot fail to have important effects upon the state of the public health should its settlement be long postponed. Up to the present, though all social workers admit that distress is keen and widespread, there has not been any marked increase of disease, at any rate among adults. There is not any unusual pressure on hospital accommodation, at any rate since the attacks on the police and the consequent retaliations in the early days of the dispute. Among infants there has been an excessively high mortality during the past few weeks, which, though due primarily to the prolonged dry summer, must have been accentuated by the present distress. Many relief agencies are doing useful work among those out of employment. On each of the last three Saturdays a relief ship loaded with supplies of household provisions has arrived in the river from Manchester. In addition, provisions are dispensed at Liberty Hall, as the headquarters of the Irish Transport Workers' Union are called. It is natural that the system of distribution has not been perfect, and abuses have arisen. Some of the supplies of food have been sold by the recipients, and the money spent in the purchase of drink. On the whole, however, there is little doubt that the supplies have reached those for whom they were intended. A relief fund for women and children only has been organised by the Lady Mayoress and a committee of ladies, and has reached some £500 or £600, in spite of a somewhat chilling reception by the daily press, which, having taken a definite stand against the workers, appears to regard assistance given in any form to those in distress arising out of the dispute as a subsidy to one of the parties. The Lady Mayoress's committee spends most of its funds in supplying free meals in the schools, and has enlisted the cordial help of the teachers, many of whom are members of religious communities. The sisters who visit the poor in their homes also undertake to distribute assistance in needy cases, and the coöperation of the Jubilee nurses has been freely given. In the early days of the dispute some anxiety was felt by hospitals and other institutions, as well as by private consumers, as to their coal supplies. At present, however, the coal merchants are meeting all orders. More recently some inconvenience has been experienced with regard to the delivery of other goods. In particular, there has been a scarcity of nitrous oxide gas on a few occasions, and the dealers can never be confident of having a supply in hand.

Excessive Claims for Sickness Benefit.

The Irish Insurance Commission has recently appointed a committee of inquiry for the following purposes: (*a*) "To investigate the question of excessive claims for sickness benefit and of the safeguards to be taken to prevent insured persons from receiving sickness benefit unless they are properly entitled thereto; and (*b*) to formulate and submit to the Commission a scheme for the distribution of the increased Exchequer grant-in-aid of £91,000 which it is proposed to ask Parliament to grant next year towards the cost of medical certificates and other expenses of administration owing to the absence in Ireland of medical benefit under the National Insurance Act, 1911." The committee is to take evidence on the various points of the terms of reference, and will hold sittings in certain convenient centres. Help is asked from the Approved Societies, the Insurance Committees, and the Local Medical Committees. It would appear that complaints have been made by the officials of Approved Societies that excessive claims were being made for sickness benefit. This is no doubt true, but it is equally true that many persons entitled to sickness benefit have been denied it, particularly in the case of one society. Frauds on both sides are bound to be frequent as long as no arrangement exists for obtaining the evidence of the medical practitioner in attendance on the claimant. Up to the present societies have refused to exercise their powers with regard to paying for such evidence, leaving the onus of obtaining it on the insured person. They have in some instances refused to recognise any medical certificate other than those of their own medical advisers. The Insurance Commissioners have rendered confusion worse by appointing a number of official medical advisers whose only duty in regard to sickness benefit is to detect malingering. Their competence for this task has not made itself apparent, while except in Dublin and one or two populous areas, geographical considerations render them inaccessible. Their appointment has met with opposition from the medical profession, the members of which refuse to coöperate with them in any professional way.

Assistant Tuberculosis Officers in County Galway.

At a meeting of the County Galway Medical Committee on Oct. 10th the following resolution was unanimously adopted:—

That the County Galway Medical Committee has objected to the appointment of assistant tuberculosis officers in the county for these among other reasons: the Prevention of Tuberculosis (Ireland) Act and the sanatorium benefit clauses of the Insurance Act have now been in operation for two and a half years in this county. The majority of the people in the rural districts who suffer from tuberculosis are not insured persons. Up to this we have seen no steps taken to give efficient treatments to these poor people, for we cannot regard the appointment of medical advisers or assistant tuberculosis officers as being of adequate assistance to meet the exigences of the case.

Malingering under the National Insurance Act.

At a meeting of the Irish Medical Committee held in Dublin on Oct. 7th it was decided to advise all Local Medical Committees to act in reference to the inquiry proposed to be held by the Irish Insurance Commissioners through the central body—the Irish Medical Committee. The matter came before the Belfast Medical Committee on Oct. 10th, when it was decided to reply to the Commissioners' letter asking members of the Belfast Medical Committee to give evidence before an inquiry to be held into the question of undue sickness under the Insurance Act, and also as to the best way to allocate money that it is supposed will be voted next session, that the time was far too short to prepare a report on a matter requiring such careful consideration. The feeling was that the Commissioners should approach first the Irish Medical Committee on such matters. It was also arranged to appoint a subcommittee to prepare evidence for subsequent use if required.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

A New Vaccine for Gonorrhœa.

AT the Académie des Sciences, on Oct. 6th, M. Laveran presented the discovery of a vaccine for gonorrhœal infection by Dr. Charles Nicolle, director of the Institut Pasteur at Tunis. Dr. Nicolle, to whom already we owe many valuable researches on cholera, trachoma, whooping-cough, and typhus, has been working for more than a year at the vaccine treatment of gonorrhœa. He has prepared a vaccine from micrococci killed by a special procedure, of which he has not yet published the technique. He prefers, he says, to

keep his method a secret, because its application may be shortly extended to other infectious diseases, and he wishes to establish his priority in this research. His experiments were finished in July, 1912. He was then assured of success, but preferred to wait so as to increase the number of his clinical cases and to present statistics that could not be gainsaid. More than 200 patients of all nationalities have been treated at the Institut Pasteur, Tunis, during the year. Dr. Nicolle and his colleague, Dr. Blaizot, have not had a single failure in either acute or chronic cases. Professor Laveran, in communicating this discovery to the Academy, gave some very interesting information on the vaccine therapy of this affection. The treatment is simple. Three or four hypodermic or intravenous injections are given every two or three days of 2 c.c. of a solution containing several milliards of micrococci. With the first injection the pain and malaise disappear. In chronic cases the patients are cured by the third or fourth injection; in acute cases a definitive cure is obtained in less than 15 days. The frequently dangerous complications which strike at the very source of life, microbic rheumatic sequelæ, are rapidly cured. But the most marvellous effects are seen in the purulent ophthalmia of the newly born. A single injection suffices to cure an ophthalmia neonati. The treatment does not occasion the least reaction, not even the slightest fever. Dr. Nicolle announces that on his return to the Institut Pasteur, Tunis, he will place at the disposal of medical men such quantities of the vaccine as may be necessary.

Congress of the Association Française de Chirurgie.

This congress was held in Paris from Oct. 6th to 11th under the presidency of Professor Kirmisson. His opening address was on the history of orthopædic surgery, its present condition, its aims and methods. The order of the day contained three subjects: The curative treatment of ankylosis by the operative method, by Dr. Baumgartner, in which he described the various methods, the reasons for choice, and the indications for operation. His co-reporter, M. Denucé, of Bordeaux, indicated the operative procedures for radical cure, applicable in the ankylosis of each particular joint—the temporo-maxillary, shoulder, elbow, wrist, fingers, hip, knee and foot, and also the post-operative treatment. A free discussion followed and Dr. Baumgartner replied. M. Pierre Duval's paper was on the surgery of the pelvic colon and its operative technique, while his co-reporter, M. Patel, of Lyons, dealt with the surgical pathology (excluding cancer), traumatic lesions, congenital malformations, faulty position of the pelvic colon, simple and specific inflammatory affections, and benign tumours. This subject was also well discussed. The last subject concerned the treatment of wounds of the skull by small-bore projectiles, and was dealt with in excellent papers by Dr. Demoulin and Médecin Major Billet. Dr. Laurent, of Brussels, under this heading made a communication on the lessons of the Balkan war from the standpoint of military surgery. He favoured early intervention, and urged the provision of ambulances with all necessary material, including radioscopic apparatus, as near as possible to the fighting line. Dr. Payo, of Königsberg, gave demonstrations of his procedure in articular resections. A very interesting presentation of apparatus closed the congress. For the next session Dr. Maunoury, of Chartres, was elected president, Dr. Walther vice-president, and Dr. Jean Louis Faure secretary.

Congress of Pædiatrics.

This congress was held in Paris on Oct. 3rd and 4th under the presidency of Dr. Netter. Nearly all the chiefs of the services of the Paris Children's Hospitals were present. Dr. Le Gendre read a noteworthy paper on the obesity of children, in which he referred to the difficulty met with in making mothers understand that excessive fatness in children was an indication of defective nutrition. But while this view was now generally accepted, the physiological causes of this trouble were not known. Nevertheless, it must be admitted that the glands of internal secretion were in some way responsible, but as these glands were numerous — thymus, suprarenals, hypophysis, &c. — the medical man was often embarrassed to know to which group to direct his attention. Dr. Marcel Nathan was commissioned to report on the glandular obesity of children and Dr. Mouriquand on the adiposo-genital syndrome in children. The subject was well discussed. The second question, cerebral tumours in children, was taken up by Dr. d'Astzos, while M. Terrien dealt with the ocular symptoms of cerebral tumours, and M. Broca and M. Français with their surgical treatment. Communications were made by M. d'Oelsnitz on the thermic, respiratory, circulatory, and hæmatologic reactions caused by heliotherapy and on the indications for heliotherapy in tuberculous affections of childhood; on heliotherapy in tuberculous peritonitis, by M. Jaubert; on the diagnosis of pulmonary tuberculosis in the nursling by rapid radiography, by MM. Ribadeau-Dumas, Albert Weil, and Maingot; and on respiratory exercises with the spiroscope, by M. Pescher.

Memorial to Professor Fulgence Raymond.

On Oct. 5th the bust of Professor Fulgence Raymond was unveiled in the presence of a large gathering of members of the Faculty of Medicine at St. Christophe-sur-le-Nais, Indre-et-Loire. In 1894 Professor Fulgence Raymond succeeded Professor Charcot at the Salpêtrière. He became a member of the Académie de Médecine, and died in 1910 at his worktable in Poitou. Addresses were made on behalf of the Government and by Professor Dastre, Professor Landouzy, and Professor Raphaël Blanchard.

General Spinal Anæsthesia.

On Oct. 1st Professor Jonnesco, of Bucharest, reported that out of 11,324 operations he had not had a single death. He had obtained deep and lasting anæsthesia, extending over the entire field of operation, with minimum doses of the anæsthetic. It had sufficed to multiply the punctures of the spinal cord, which are made as close as possible to the nerve roots. The injections are made between the third and fourth cervical vertebræ for operations on the head; between the first and second dorsal vetebræ for operations on the neck; between the last dorsal and first lumbar (in conjunction with the last named) for operations on the upper limbs and the upper part of the thorax, and alone for operations on the abdomen and the lower limbs; between the fourth and fifth lumbar vertebræ (in conjunction with the last named) for operations on the pelvis, and alone for operation on the perineum.

A New Hospital at Villejuif.

The Act of 1905 on compulsory assistance necessitated the opening of special establishments for such aged and incurable persons as could not be maintained at home. The first of these institutions has now been opened at Villejuif by the Department of the Seine, and although it has not been officially inaugurated, M. Magny, Director of Departmental Affairs, has taken all the necessary measures for the admission of 1000 aged persons. This number will be increased later to 1500. Dr. Gustave Roussy has been appointed chief physician with Dr. Méténier as his colleague.

Oct. 13th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

Pellagra in the Province of Rome.

A DISTINGUISHED commission has been investigating during the past year the subject of pellagra in the province of Rome, and has published a preliminary report in the *Policlinico*, Sezione Pratica. They find that there is a great deal of inaccuracy in the diagnosis of the disease, for of 208 notified cases they were only able to concur in the diagnosis in 46, and among these were included several doubtful cases. The disease is rare and not on the increase; it is limited to a certain few villages where it has long existed. There seems no relation between the consumption of maize and the incidence of the disease, for maize is eaten at practically every meal in all the districts investigated. Nor could the disease be connected with the bites of any insect. On the other hand, the villages where the disease occurs show marked differences in the water-supply as compared with those that are immune. Generally speaking, the province of Rome is uncommonly well supplied with water, but where the cases of pellagra occurred either the village had a bad water-supply, surface waters badly protected, or the patients were in the habit of using such waters found in the neighbourhood of their dwellings.

The General Elections.

The general elections which are to take place at the end

of this month are the absorbing interest of the hour. The introduction of the principle of manhood suffrage at this election increases the electorate from 3½ to 8½ millions. Naturally there is a good deal of doubt as to what changes in the representation of the parties in the Chamber this enormous increase of the electorate may effect. The Socialists openly state their fear of the influence of the priests on the more ignorant section of the new contingent of voters. A part of the medical press urges the profession, and especially the "medici condotti," or parish doctors, to use their undoubted influence to secure the return of candidates pledged to sanitary reforms and the consideration of the doctors' grievances. Of these, the chief is the treatment accorded to the "medici condotti," their miserable pittances, hard terms of service, and the scant consideration with which they are treated by both local and central authorities.

Antityphoid Inoculation in Tripoli.

In the *Nuova Antologia* Surgeon-General Ferraro di Cavallarleone reviews the results of antityphoid vaccination of the troops in Libya. This was initiated by himself in August, 1912, at Tripoli. Up to June, 1913, 16,191 vaccinations were made, of which 6696 were first inoculations, 5427 second, and 4068 third. The results were: among those inoculated once, 9 cases of typhoid fever with 3 deaths—i.e., 1·34 per 1000, with a mortality of 0·4 per 1000; among those inoculated twice, 9 cases with no death—i.e., 1·65 per 1000, with mortality 0; and among those inoculated three times, 0·49 per 1000, with mortality 0. During the same period the incidence of the disease among the unvaccinated in Libya was 35·3 per 1000, with a mortality of 7 per 1000.

Oct. 11th.

Obituary.

CHARLES LESTER LEONARD, M.D.,

PROFESSOR OF ROENTGENOLOGY, UNIVERSITY OF PENNSYLVANIA.

BY the death of Dr. Charles Lester Leonard, of Philadelphia, another victim is added to the list of those roentgenologists who have succumbed to the perils peculiar to their professional duties.

Dr. Leonard was born in 1861 and received his medical education at the University of Pennsylvania, where he took his M.D. degree in 1881. He became later Professor of Roentgenology there. First his hand became affected and had to be amputated. The arm followed, and this, too, was removed, but the disease did not stop but affected the entire body, so that he died on Sept. 22nd at Atlantic City, New Jersey. He was not a voluminous writer, though he contributed interesting papers on the malarial parasite to the *International Medical Magazine* and on a new method of studying cell motion to the *American Journal of the Medical Sciences*, besides several contributions to the medical journals on X ray subjects.

Dr. Reginald Morton writes: "The passing of Lester Leonard is a serious loss to medical science and in particular to radiology. Like too many other pioneers in this dangerous branch of medical work he has paid for his enthusiasm and interest with many years of patient suffering and finally with his life. His keenness for his work never wavered, even to the end, when he postponed a necessary operation that he might complete his report on the radiography of the digestive system for the Section of Radiology in the International Congress of Medicine recently held in London. Since first meeting him in London in 1904—his hands even then were seriously damaged—we have met at congresses in Toronto, Niagara, Amsterdam, and in 1907 he came to the annual meeting of the British Medical Association at Sheffield, where he gave an address on the X-ray examination of the thorax. Throughout these years it was evident that the dermatitis was becoming more extensive and certainly not less painful, but in spite of all this he was as devoted to his subject as ever, and he was at all times a genial and pleasurable companion. In the world of radiology the name of Lester Leonard will be remembered for a long time to come. His interest was not limited to any one branch more than another—he has done yeoman service in the development of every department. His constant aim was the attainment of the highest possible perfection and accuracy of his results."

Mr. Deane Butcher writes: "Radiology has to lament the loss of another of the few remaining pioneers in the person of Dr. Lester Leonard, of Philadelphia—one more victim to the Baal fire of the Roentgen rays. Dr. Leonard was for many years a familiar figure at most of the Roentgen congresses and was well known in this country as a frequent contributor to the *Archives of the Röntgen Ray*. It was due to his initiative that a Radiological Section was added to the International Congress of Medicine, and it is a touching evidence of his devotion that he delayed a necessary operation in order to finish his report on radiography of the stomach which he communicated to that section. We have lost a keen investigator, a good comrade, and a charming personality by the death of Dr. Lester Leonard."

FREDERICK ROYSTON FAIRBANK, M.D. HEIDELB., F.R.C.P. EDIN., F.S.A.,

CONSULTING SURGEON TO THE DONCASTER ROYAL INFIRMARY.

Dr. Frederick Fairbank passed away at Felixstowe, Caversham, in his seventy-third year, on Oct. 3rd. Educated at Rugby School, Manchester Medical School, and King's College, London, he qualified M.R.C.S. Eng., L.R.C.P. Lond. in 1862, and practised for a time at Lynton, then for many years at Doncaster, where he had an excellent practice. As he began to suffer from rheumatism and bronchial asthma, in 1892 he removed to St. Leonards, and later to Dorking, from which he retired (having sold his practice) about three years ago to Caversham. In 1865 he obtained the M.D. degree at Heidelberg. He had been a Fellow of the Royal Medical and Chirurgical Society since 1869. In 1874 he obtained the M.R.C.P. of Edinburgh and in 1892 the Fellowship. Among excellent contributions to professional literature was one on digitalis in the Clinical Society's Transactions, and one on some successful tarsectomies for talipes equino-varus in adults. Dr. Fairbank designed a very useful clinical note-book. In archæology he was a well-known authority, having been a Fellow of the Society of Antiquaries since 1888, and contributing much to the Associated Architectural Societies' Reports, to Memorials of Old Surrey, and having done some excavations at Roche Abbey. He was twice married, and leaves a widow and three children to mourn their loss.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. L. Jagot, professor of clinical medicine in the Angiers School of Medicine.—Dr. J. Bonet y Amigo, professor of midwifery and gynæcology in the University of Barcelona.—Dr. M. Volkoff, professor of pathology and therapeutics in the Women's Medical Institute, St. Petersburg.—Dr. Edwin W. Bartlett, formerly professor of ophthalmology and of Otology in the Medical Department of Marquette University, Milwaukee.—Dr. John G. Curtis, formerly professor of physiology in the Columbia University College of Physicians and Surgeons, New York.—Dr. James M. Blaine, professor of dermatology in the University of Colorado School of Medicine, Denver.

DONATIONS AND BEQUESTS.—The late Miss Anna Jane Arden has bequeathed the whole of her estate, amounting to £67,000, equally between the following institutions: St. George's Hospital, London; St. Thomas's Hospital, London; St. Mary's Hospital, Paddington; the Children's Hospital, Great Ormond-street; the Hospital for Incurables, Putney; the Hospital for the Paralysed and Epileptic, Queen-square; the Brompton Hospital for Consumption; the Deaf and Dumb Asylum, Margate; the London Surgical Aid Society; and five other charities.—Among other bequests the late Mrs. Anne Sutton, of Burton-road, Derby, has left £3000 to the Derbyshire Royal Infirmary, £500 to the Derbyshire Hospital for Sick Children, £500 to the Royal Institution for the Deaf and Dumb, Derby, and £500 to the Queen Victoria Home of Rest, Derby.—The Master of the Heythrop Hunt has sent a second donation of £500 to the Banbury Infirmary.—The Midland Railway Company has forwarded a cheque for 200 guineas to the Cumberland Infirmary, Carlisle, in recognition of assistance rendered on the occasion of the Aisgill accident.

Correspondence.

"Audi alteram partem."

EXAMINATIONS, EXAMINERS, AND EXAMINEES.

To the Editor of THE LANCET.

SIR,—Sir William Osler would probably be surprised, perhaps even disappointed, if his thoughtful and trenchant address were meekly swallowed, like a dose of medicine, without remonstrance. I agree with much that he says, but not with his suggestion that English surgery would be stimulated if the Council of the Royal College of Surgeons of England were to select for the Fellowship each year 15 or 20 of the men under 30 who had distinguished themselves most highly in surgical research. Research is becoming a greater fetish than the examination test. To practise research is not the only way to become a good surgeon. A great many excellent surgeons are not fitted for what is known nowadays as research, and much of what I should call research would not be recognised as such by the censors. It is common to hear of heart-burning and bitter disappointment amongst those who aspire to be Fellows of the Royal College of Physicians and Fellows of the Royal Society—some of them "Olympic athletes" and "picked steeplechasers of our stables," much more worthy of those titles than many of the candidates for the Primary Examination for the Fellowship.

I should like Sir William Osler to devote an afternoon to listening to this examination. I think he would be convinced that many of these athletes are imperfectly trained, if they are not, as I believe is often the case, merely having a sporting shot at the examination. The questions, in anatomy at all events, are simple and straightforward; the ignorance of rudimentary facts is often deplorable. I cannot estimate so well the questions and answers in physiology. It would be interesting to hear Sir William's judgment upon them.

I do not say that the condition of things is quite satisfactory, or that the standard might not with advantage be to some extent relaxed, or that our system is above criticism; but I do maintain that the method of admission by examination is preferable to the suggested alternative. It must be remembered that the Fellowship is not a necessity, that it is the most highly prized British surgical distinction, and that it is supposed to show, and does show, that those who obtain it are not only able to pass a severe test, but have had a special training in anatomy, physiology, pathology, and surgery. It might be well if the number of Fellows were somewhat larger, but not if it involved the inclusion in their ranks of such "steeplechasers" as do not recognise the ligaments of the ankle-joint or the corpus callosum when they see them.

With regard to the general question of why students are ploughed in such appalling numbers at most medical examinations, I believe the reason is to be found in the system of demonstrations and cram classes which has grown to such inordinate proportions during the last 40 years and which leaves the students no time for thought. This is due to the feverish competition amongst the schools, and as long as they retain their present constitutions it is difficult to suggest a practical remedy. Those put forward by Sir William Osler will no doubt obtain the very serious consideration which they deserve. Let it not be forgotten, however, in thinking out the problem, that the students are not passed through a very fine sieve on entering upon their career, that many of them drop out for other reasons than failing at examinations, and that, after all, the proportion of those who begin medical studies and fail to qualify is, as nearly as can be ascertained, not more than 25 to 30 per cent.

I am, Sir, yours faithfully,

Wimpole-street, W., Oct. 15th, 1913. RICKMAN J. GODLEE.

NATIONAL INSURANCE ACT: THE DIFFICULTY OF CERTIFICATES.

To the Editor of THE LANCET.

SIR,—I have replied to the National Health Insurance Commission (England) in response to the receipt of a Memo. 173/I.C., concerning medical certificates, as follows:—

"Having carefully read and considered the above memo. and three enclosed certificate forms, while wishing for uniformity in the matter of certificates, I have formed the conclusion that to attempt to bind the doctors down to a hard-and-fast rule as regards the dating of these, as is proposed in Sec. 10, par. 3, will be impossible without inflicting great hardship on the doctors, and adding a fresh duty—one entirely clerical—to his already onerous duties in the busy time of the year."

I pointed out also to the Insurance Commission, and should like to bring the matter before your readers, that most, if not all, of the Approved Societies require medical certificates to be signed every week during illness and on one particular day, not the same day in every instance, but each seventh day from the commencement of the illness. If the certificate is dated, say, on the day before the exact week end—i.e., on the sixth day—the pay for the missing day is deducted from the weekly amount due. In the case of patients attending at the surgery the patient generally arranges to make one of his calls on the day his certificate requires signing. But in the case of those who have to be visited at their own homes, this certificate signing on one particular day and no other each week is a great hardship to the medical man, who must go to his patient's house—which may not be quite near—whether the case requires a professional visit or not, on that particular day, simply to perform a clerical duty. If he fails to do so, his patient will lose his pay for that week. If he is at the patient's house the day before or the day after the exact date, he cannot sign the certificate. When these cases are multiplied in the busy season and during the winter months, greater inconvenience and increase of labour will be involved.

In order to avoid this I have brought before the Insurance Commission the question of antedating and postdating certificates, suggesting that such action should be left to the discretion of the doctor. I suggest, first, that the words "to-day" in "I have to-day examined," &c., which appear in all three certificate forms, be deleted; and, secondly, that the words, "but certificates should not in any circumstances be antedated or postdated," be withdrawn.

I am, Sir, yours faithfully,

W. W. HARDWICKE, M.D. St. And.

Carlyle-square, S.W., Oct. 12th, 1913.

NATIONAL INSURANCE ACT: MEDICAL REFEREES AND MALINGERING.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Oct. 11th Mr. Albert Benthall writes: "It is one of the settled ethical laws which govern the profession that, knowingly, no medical man shall examine the patient of another medical man except in consultation or after having first obtained his consent," and he then proceeds to argue that medical referees appointed by Local Insurance Committees to check malingering will be obliged to conform to the above rule in the examination of cases referred to them.

I would like to point out that so far as I am aware no such rule exists. It is not to be found in the rules laid down for their diplomates by the various licensing bodies, while the Birmingham and District General Medical Practitioners' Union, which goes farther than any other body in endeavouring to secure the interests of general practitioners, formulates no such rule. The position of a medical referee is not new, nor are the difficulties connected with it unfamiliar, but it is certain that he cannot be trammelled in the execution of his duty by a rule which would make it impossible for him to examine the case in the absence of the usual medical attendant or from the latter's refusal to give his consent to the examination.

I am, Sir, yours faithfully,

Birmingham, Oct. 13th, 1913. ROBERT SAUNDBY.

LONDON MEDICAL COMMITTEE.

To the Editor of THE LANCET.

SIR,—With your permission I would draw the attention of the non-panel section of the profession in London to the efforts of the London Medical Committee (an entirely non-panel body) in promoting the formation of non-panel associations in the county of London. There are already three of these associations in existence—at Hampstead, Wandsworth, and Lewisham, and others are in the course of formation.

It is of extreme importance that non-panel men should keep actively in touch with each other and prepare by combination to meet the increasing attacks upon their interests. The British Medical Association has shown that the non-panel man can expect little assistance from the Association, and it is only through a body formed exclusively of non-panel men that he can obtain prominence for his views and any chance of being heard. It therefore behoves every man who has no intention of working under the panel system to become a member of the non-panel association in his division, and if such an association has not yet been formed in his division to make endeavours to start one.

I shall be glad to receive any communications addressed to me at 45, Welbeck-street, W., and give any information in my power.—I am, Sir, yours faithfully,

E. ARTHUR DORRELL,
Honorary Secretary, London Medical Committee.

Oct. 11th, 1913.

NATIONAL INSURANCE ACT: TITHERINGTON *v.* DUNLOP.

To the Editor of THE LANCET.

SIR,—The recent decision of the Liverpool county court judge in the case of Titherington *v.* Dunlop that the contract of service is between the panel patient and the doctor is, I submit, open to question. If this decision is allowed to stand I can easily foresee that a great deal of trouble is likely to arise between patients and doctors. In future any panel patient with a real or fancied grievance need not approach the Local Insurance Committee, but he can at once serve a writ upon his doctor, and thus pave the way for a species of blackmail.

In these circumstances it seems to me imperative that the result of this case ought to be appealed against, and that panel doctors as a whole should combine to make this possible by subscribing to a fund to defray the cost, as the respondent cannot be expected—even if he were willing—to fight a battle which affects the whole of the panel practitioners. Personally I shall be glad to aid in every possible way—pecuniarily and otherwise.

I am, Sir, yours faithfully,

Liverpool, Oct. 7th. FINSON.

THE PATHOLOGY OF THE CONDITION KNOWN AS PARASYPHILIS.

To the Editor of THE LANCET.

SIR,—It must be a matter of deep gratification to us to find that our pathological conclusions lead to the same practical end as the observations of a physician so widely experienced as Dr. F. J. Smith. Since Dr. Smith invites us to consider a particular case we will endeavour to do so.

This patient was first seen by Dr. Smith in 1895, and had contracted syphilis "in the year of the Paris Exhibition," presumably that held in 1889. Thus six years after infection he had cerebral symptoms of sudden onset which entirely receded before mercury and iodide in three months; clearly a vascular condition. Two years later—that is, eight years after infection—he had an acute cerebral attack with delusions, which also rapidly subsided under antisyphilitic treatment, although slight remnants of nerve injury persisted for a few years.

Dr. Smith considers that it is anomalous to refuse the name of "early general paralysis" for this condition, and certainly it is on the borderline between "early encephalitis" and "dementia paralytica." In our opinion, it illustrates the contention we put forward—namely, that there is no essential pathological distinction between the two lesions, and this was no doubt one of the transitional forms. Personally, however, we would withhold the name "general paralysis," because this expression conveys to our mind a series of clinical manifestations which end in death. Our impression may be incorrect, but it is nevertheless one which is popularly prevalent. This patient, however, was completely cured. In order to illustrate what we take to be the pathology of such a case, we will reduce the argument to a state of simplicity which is probably unjustifiable. The toxicity of a microbe is not an absolute quantity, but is an expression of its effect upon the infected host. Thus a microbe may be highly toxic to one animal and yet non-toxic to another of a different species. Further the apparent toxicity of the microbe may vary in animals of the same species. It is not so much that in one case the virulence is "exalted" while in the other it is depressed, but that the *susceptibility of the two animals is different*. We will go one step further in the argument and point out that the toxicity of one and the same microbe may vary in one and the same host at different times. This is almost certainly not due to any alteration in the virulence of the microbe, but to an alteration in the susceptibility of the patient. This phenomenon is well illustrated in syphilis. The primary chancre is the expression of the local susceptibility of a normal person to S. pallida. It is a reaction which measures, for instance, $\frac{1}{2}$ inch. The secondary rash is a series of local reactions, each of which is much smaller because the local susceptibility has been diminished. In fact, the rash may be trivial and the patient feel quite well, although he has nevertheless many spirochætæ in his system. Thus it may be said that there is very little toxicity in S. pallida unless the tissues are susceptible to its toxic action. At this stage the immunity mechanism comes into operation and slowly develops a protective state, so that in the tertiary stage the cells are, as it were, on the *qui vive* to an excessive extent. They will immediately burst into operation (react) on the appearance of the smallest number of spirochætæ. The cells may be described as being hypersusceptible to the spirochæta, and, conversely, the spirochæta as hypertoxic to the cells. In this stage, therefore, a minimal number of microbes will produce a maximal lesion. If the site of exacerbation of the spirochætæ is the lymph vascular tissues, a "gummatous" reaction will result; if they are situated among parenchymatous cells, a parenchymatous reaction follows. The parenchyma cell, however, differs from an interstitial cell in being particularly "delicate." If it receives an injury of a certain intensity it fails to recover and degenerates. A condition then results which has been called "a primary degeneration" and "a diffuse fibrosis" (brain G.P.I., testicle, liver, &c.). The practical effect is an irreparable loss of function.

Thus "general paralysis" is a condition due to a small number of spirochætæ acting upon hypersusceptible nerve cells. The injury is so rapid that the diagnosis could never be made early enough to counteract it before the limit of tolerance had been reached in the cell. In an early secondary encephalitis, however, the cells are very little susceptible, and although the spirochætæ are here more numerous, a long interval of time is available in which to apply treatment before the cells are materially injured. If treatment is not applied, the case will drift into a condition which for practical purposes resembles general paralysis. Dr. Smith's case, we imagine, occurring eight years after infection, was in a condition of medium susceptibility: he was on the high road to becoming a "general paralytic," but the process was sufficiently slow to allow Dr. Smith to intervene successfully; only a few cells were beyond repair, and these apparently of little significance. The danger of these cases lies in the probability that their nature will not be recognised, and by the time the diagnosis is decided upon the destruction has exceeded the limit of repair. In this particular instance Dr. Smith suspected typhoid fever, but since he holds that a patient suspected of having had syphilis and suffering from any disease should receive antisyphilitic treatment, he immediately ordered mercurial inunctions, and thus possibly saved the man's life. We should say that the patient would have developed "general paralysis," but that he was not a "general paralytic" at the time. A name for the clinical condition we do not suggest: it was a syphilitic encephalitis. The only essential of practical importance is that, in Dr. Smith's own words of seven years ago, "in all such cases mercury should be very freely and promptly administered." At the present

time this recommendation should apply to salvarsan, since there can be no controversy over the relative merits of the two drugs.

Finally, so far as our own investigations are concerned, we must admit that Dr. Smith is correct in the tentative conclusion contained in his final paragraph. We think that it is essential to apply treatment at once without waiting for the Wassermann reaction; firstly, for the reason that valuable time must not be wasted, and secondly, because the treatment will not affect the result of the reaction within any reasonable number of days. It should be applied after treatment has begun. The great merit of the test is not only that it greatly assists in an accurate diagnosis and is almost essential to a prognosis, but it establishes the nature of a case conclusively, although there might be no suspicion of syphilis, and thus permits of a much more thorough treatment than would be applied if the case were left in obscurity.

We are, Sir, yours faithfully,

JAMES MCINTOSH,
PAUL FILDES.

London Hospital, Oct. 13th, 1913.

THE MEDICAL MISSIONS OF THE SOCIETY FOR THE PROPAGATION OF THE GOSPEL.

To the Editor of THE LANCET.

SIR,—I wish to make known some openings for junior members of the medical profession which, putting aside other aspects of the work, provide a variety of cases and scope for the performance of important operations greater than commonly fall to the lot of general practitioners in this country. In the majority of these places there can be also the inspiring reflection that there is no other qualified doctor within many miles to whom the patients could possibly apply for the treatment they need. The salaries, except in the case of Rusapi in Mashonaland, where there is a Government guarantee of £300, besides private practice, are small, but sufficient for comfortable maintenance of unmarried doctors, being the same both for men and women as those offered to the clergy working under similar conditions on the S.P.G. Missions in connexion with which these posts are.

The doctors must be in full sympathy with mission work, but will not be required to do any but their professional work, unless they desire it themselves. The vacancies are: for men (1) Hazaribagh, Behar, India; (2) Rusapi, Mashonaland; (3) Kwamagwaza, Zululand; for women, (1) Ping Yin, North China; (2) Delhi, India; (3) Malacca. In all these places the hospitals are in full working order. Several more men are wanted for China and three women for India, but we cannot send them at present owing to lack of funds. Our men never enter into competition with private practitioners or with those working in Government posts. We appeal to members of the medical profession who are in sympathy with the efforts which the Society for the Propagation of the Gospel is now making to meet the great need for medical aid in places otherwise unprovided for, to help us by bringing these vacancies to the notice of some who seem suited to fill them. I shall be glad to answer fully any inquiries made from me about these posts and the needs and plans of this department of the S.P.G.

K. W. S. KENNEDY, M.B.,
Secretary, Medical Department, S.P.G.

Westminster, Oct. 14th, 1913.

OUR SYSTEM OF MEDICAL TRAINING.

To the Editor of THE LANCET.

SIR,—With your permission I should like to express my grateful thanks to Sir William Osler for his address at the St. George's Hospital Medical School and humbly to express my opinion that it is one of the finest of the many services which he has rendered to the profession.

I am sure that from his pronounced intention of improving the profession he will not object to some of his statements being supplemented by an opinion which is held by many that the "passed" men are, metaphorically speaking, mentally and professionally dead for some time after their success. Some recover their old brilliance, but a very large percentage is permanently damaged by the training.

The rejected men must of necessity go to swell the ranks of the "unemployables."

This opinion is not a whit too severe when we consider the results of the treatment of the "*flower of the young intellect*" of this country. He does not touch upon the public aspect of the present system of training, in particular with its relation to clinical medicine. Students and teachers alike receive their clinical training from observations upon the "submerged tenth." Now, 50 per cent. of the passed men will enter general practice and try to be useful to the respectable working and middle classes, from whom alone it is possible to expect a living wage. It is obvious that the "system" places upon the community a mass of men clinically untrained for the duties they have to perform.

The most serious and tangible indictment of the "system" is the mass of literature we (one and all) daily receive relative to proprietary drugs and methods of treatment of disease. All the literature comes from commercial people outside the profession who would not send it and incur great expense unless there were an adequate return. I often wonder how the profession as a whole can tolerate this daily insult. It does not redound to the credit either of teachers or examiners, and emphatically not to the Council for Medical Education.

The desire to see professional training of such a nature as to make the profession a part of each man who practises it is my apology for trespassing upon your space.

I am, Sir, yours faithfully,

R. CRAWSHAW HOLT.

Manchester, Oct. 13th, 1913.

THE BOUNDARY LINE.

To the Editor of THE LANCET.

SIR,—May I ask you to publish an objection to a custom which appears to be growing in some quarters of the profession? I refer to a habit which a class of consultant indulges in, of sending broadcast to general practitioners copies of lectures which he has given upon medical subjects. When I receive from a consultant with whom I have had professional relations a paper of his I value it and read it with attention, but when I receive a pamphlet from a gentleman whom I do not know I regard it as a tradesman's circular and treat it as such.

To-day I have received yet another of these, with, in addition, a slip informing me that the writer is "specially interested" in certain disorders, and would be glad to have details of cases from me. I do not know the author, I have never heard of him, and therefore he may be, for anything I can tell to the contrary, a master of his specialty, but as I am never likely to feel myself desirous of testing the point by inviting him in consultation, I am not sufficiently interested in his achievements to undergo the fatigue of reading about them.

Of course, he may have included my name in the list of those to be favoured with his pamphlet by error. Yet these errors are of such frequent occurrence that although I am eager to believe such explanations, for the dignity of the profession, yet I have had, very often, great difficulty in doing so. Indeed, if the custom continues I shall find myself forced to regard it as nothing more than a vulgar device for advertising the authors. I hope these gentlemen will not drive me and my fellow practitioners to this extremity. I enclose the "trade circular" in question.

I am, Sir, yours faithfully,

C. WILLETT CUNNINGTON.

Church End, Finchley, N., Oct. 11th, 1913.

AN INVESTIGATION INTO INDUSTRIAL INSURANCE.

To the Editor of THE LANCET.

SIR,—The Fabian Research Department, in compliance with numerous requests, has started a detailed investigation of the various forms of industrial insurance, beginning with the working of the National Health Insurance Act. The investigation will have for its sole purpose to discover what actually is the effect of the Act, and in what way its operation can be improved. Will you permit me to invite insured persons, doctors, nurses, members of Insurance Committees, and workers in any way connected with Friendly Societies—such as sick visitors, agents, secretaries, branch secretaries, &c.—to contribute facts or other information which they think would be of service?

We should, for example, be very pleased to receive copies of the minutes and regulations of Insurance Committees;

particulars of societies' admission or refusal; expulsion or transfer of members, or refusal of permission to transfer; adequacy or inadequacy of medical treatment; success and failure of the sanatorium benefit; medical attendance available for persons leaving home or away from home; the working of the maternity benefit; and so on. We want to hear of every example of satisfaction or success, as well as of every grievance or failure, and to explore all the results that can be yet traced. For this we can rely only on the kind coöperation of the press and the public.

I am, Sir, yours faithfully,

SIDNEY WEBB.

Fabian Society Research Department, 37, Norfolk-street, Strand, W.C., Oct. 10th, 1913.

WILLIAM LANGLEY MEMORIAL FUND.

To the Editor of THE LANCET.

SIR,—I should feel much obliged if through the columns of THE LANCET you could make it known that subscriptions to the above fund received by my bankers, Sir Charles R. McGrigor and Co., 25, Charles-street, St. James's, S.W., will be transferred to the committee at Lagos, Southern Nigeria.

I am, Sir, yours faithfully,

J. P. FAGAN.

Scarsdale-villas, Kensington, W., Oct. 10th, 1913.

SNAKE STONES.

To the Editor of THE LANCET.

SIR,—In an account of "An Irish-American Talisman" on p. 506 of THE LANCET for August 16th last mention is made of "snake stones." Perhaps a description of some which I have seen may interest your readers. The two "stones" which I have seen measure about three-quarters of an inch by about two-thirds of an inch—one being roughly triangular, the other more oval. They are about a quarter of an inch in thickness, one side being flat and the other rounded, and are both of a colour as black as jet—a substance which in consistence they somewhat resemble. They are certainly not at all like any ordinary stone. I have seen four cases of "snake-bite" treated with these stones. In no case did the patient appear to me to suffer from any symptom but fright, but they were all put down as cures. In two of the cases I think possibly the people had been bitten by non-poisonous snakes. In the other two I think the snakes only existed in the sufferers' imagination.

The owner of the stones is a Babu man, and must have a considerable practice, for he is said to have refused as much as 1000 rupees for one stone. The method of cure is as follows. One or both stones are applied in the neighbourhood of the wound. They adhere to the skin for some time, and when they fall off they are put for a short time into milk, by which means the poison is said to be extracted. They are then reapplied to the skin, and this process is repeated until they refuse to stick to the skin. This Babu says he got the stones from a fakir. In this part of the world "snake stones" are said to be found "on the hills," and I have heard them described by natives as the solidified saliva of the markhoy—a species of wild goat. The name markhoy means snake-eater, as the animal is popularly supposed to kill and eat snakes, and its saliva is a reputed antidote to snake venom.

A description which appeared in the *Field* in the spring of last year of a hair-ball found in the stomach of a chamois bears a striking resemblance to these "snake-stones." It appears to me quite possible that, when all remains of an animal whose stomach had contained a hair-ball had been removed by birds and beasts of prey, the hair-ball might remain to be picked up "on the hills."

I enclose a photograph of the "stones. The third, smaller and rounder, is in appearance made of the same substance as the others, but is used in cases of scorpion sting.

I am, Sir, yours faithfully,

LOUIS H. L. MACKENZIE, Captain, I.M.S.

Dera Ismail Khan, Sept. 13th, 1913.

*** Previous references to snake-stones will be found in THE LANCET of May 11th, 1867, p. 576, Jan. 31st, 1903, p. 343, and Nov. 13th, 1909, p. 1478.—ED. L.

SHIP'S SURGEONS.

To the Editor of THE LANCET.

SIR,—May I add my experience and advice to that already offered by others to those of our profession who contemplate applying for appointments in the above capacity?

It is a fact that the shipping companies at the present time are experiencing the greatest difficulty in obtaining surgeons for their vessels, and although no one would desire to take undue advantage of their embarrassment, it is nevertheless a favourable and unique opportunity for establishing a fair rate of remuneration and for insisting on reasonable accommodation and comfort. For instance, the leading Company trading to the East, the Peninsular and Oriental, has recently been paying £20 a month to surgeons, instead of its usual fee of £10 a month. This is a big advance, but it cannot be considered an exorbitant one when one considers that the same company pays its chief engineers £30 and over, chief officers £20 and over, pursers and chief stewards £16 and over, and chief cooks £12. On joining the company to which I am attached I was officially assured that in addition to my pay of £10 per month I should earn in fees from passengers at least another £180 per annum, bringing my remuneration up to £300 per annum. This I have found to be ridiculously and unwarrantably exaggerated. During the last three months, all spent on mail steamers, I have received £3 10*s.* in fees from passengers.

May I therefore tender the following advice to those about to join as ship's surgeons: 1. To decline any appointment for which the remuneration is less than £20 per month, even in those companies where fees are allowed to be charged in addition to pay. 2. To obtain in writing an undertaking that "outside" accommodation will be provided—that is, an outside cabin with a porthole. Only those who have experienced them can realise the horrors of endeavouring to sleep in an inside cabin in the tropics. 3. To insist on the cabin being fitted with an electric fan. Most companies provide these as a matter of course and ordinary comfort, but there are others that do not do so without a previous understanding and arrangement; the P. and O. Company is an instance of the latter. I enclose my card.

I am, Sir, yours faithfully,

A.B.

Sept. 23rd, 1912.

THE MEDICAL PROFESSION AND THE LAYMAN.

To the Editor of THE LANCET.

SIR,—In a leading article on Oct. 4th you speak hopefully of the future of medical practice. Certainly the incomes of practitioners have not progressed in any way whatever commensurate with the improvement of their equipment. It may be the truth that there are more laymen now who appreciate the circumstances of a medical man's life than was the case not very long ago. Laymen in whose hands there may lie voting power with regard to medical appointments are coming to understand that the majority of the candidates before them will have spent £1000, and more, in the acquisition of the grammar of their calling, and that this unpaid apprenticeship will have lasted in the majority of cases at least six years. A large amount of bitterness was created between the medical profession and the public while the National Insurance Act was muddling its way through Parliament. It was completely impossible that the medical profession should acquiesce in the original proposals, but the medical position was not fortunately placed before the public either by themselves or by the political newspapers which approved their action, or by the supporters of the Bill in its original form who resented all medical protest. Time after time medical men were told that the medical profession was merely "out for money," and it is undoubted that a certain amount of harm was done to us as a body in consequence of the oft-repeated calumny. Now, however, the public is rapidly perceiving that what the medical profession said about the Insurance Act was very right; but before the medical profession as a calling becomes popular, time will have to elapse in my opinion.

I am, Sir, yours faithfully,

PARENT AND TEACHER.

Oct. 6th, 1913.

THE NATIONAL INSURANCE ACT.

THE ALLOCATION OF INSURED PERSONS.

IN a letter to the *Times* Dr. Major Greenwood has pointed out that the difficulty with regard to the distribution of surplus funds has not arisen in those places (as in the Manchester district) where payment for medical attendance is made according to the work done and not under the capitation system. In other words, the money allotted to medical attendance has there gone without question, and without any of it being withheld, to those for whose remuneration it was intended. With regard to the comparative merits of the two systems interesting information will be found in the letter of Dr. H. H. Mills published in THE LANCET of Oct. 11th, 1913, p. 1094. It is there suggested that the system of payment by work done, which the majority of the medical profession has advocated, has its drawbacks in practice for which allowance must be made, in the tendency which it has to encourage unnecessary attendances being made, and in the consequent drain upon the funds at the disposal of the committees. In considering the comparative merits of the two systems full weight must be given to the fact that payment by attendance gets rid of the difficulty arising from insured persons not selecting their medical advisers, and brings into play to the full the principle of insurance by which the contributions of those not needing the aid provided help to defray the cost incurred for the relief of those less fortunate. It must not, however, be forgotten that the surplus funds to which the opinion of Mr. Danckwerts referred have not arisen only through the failure of a large number of persons insured under the Act to select their medical attendants. They have arisen through this combined with the fact that the distribution of such patients to medical men upon the panel (for which provision is made by the Act) has not taken place. Various causes have no doubt contributed to bring this about, but the accumulation of such funds will no doubt be avoided wholly or almost wholly as time goes on, and the Insurance Commissioners or Parliament will deal with the question of moneys accumulated in a manner not foreseen when the Act was passed, through the combination of circumstances referred to.

FRIENDLY SOCIETIES AND "CONTROL OF THE DOCTORS."

At a conference of Oddfellows representing the counties of Cheshire, Shropshire, and Staffordshire held at New Brighton recently the National Insurance Act and its effects upon the Friendly Societies were discussed, and the operation of the Act in placing medical benefit under the control of the Insurance Committees was, of course, vigorously denounced. The cause of complaint was, as usual, the depletion of the funds of the societies through the amounts paid out in sickness benefits. According to a speaker, "they had lost control of the doctors, and if the lodges fancied they detected cases of malingering they were powerless. If the panel doctor was approached he would possibly tell them to mind their own business, and if they reported the matter to the District Insurance Committee they would quickly discover that they could get no assistance from that quarter." To demand the right to control the medical officer was described as seeking "the restoration of their stolen goods," and altogether there was some large talk. This does not produce the effect upon the medical profession which is intended, for all practitioners are aware that the managers of Friendly Societies do not complain because their members are having too much medical attendance, but are merely incensed because it is not provided at the club price and subject to club "control."

TO WHOM IS THE MEDICAL MAN ON THE PANEL RESPONSIBLE?—TITHERINGTON *v.* DUNLOP.

In the Liverpool county court recently G. Titherington, a minor suing through his father, claimed from J. Dunlop £2 6*s.* for expenses incurred in obtaining the services of another medical man, owing to the defendant having refused or failed to attend the plaintiff, who was a patient on his list under the Act. The dispute has, we believe, been referred to in the House of Commons. Charges were made on both sides of a contradictory character, the defendant alleging that he was prevented by the pressure of his work from attending his patient when desired to do so by the relatives, and the plaintiff's witnesses complaining of the defendant's manner towards them, as well as of his non-compliance with their request for his attendance. As to the merits of these issues the finding of the judge was in the plaintiff's favour, judgment being given for the sum claimed with costs, accompanied by an expression of opinion that the defendant had given way to temper. Leave, however, was given to appeal upon a point of law raised without success on behalf of the defendant, whose counsel contended that Section 67, Subsection 2, of the Insurance Act applied, so as to exclude the jurisdiction of the county court. The subsection referred to is as follows: "2. Every dispute between an insured person and the Insurance Committee relating to anything done or omitted by such person or the Insurance Committee under this part of this Act, or any regulation made hereunder, shall be decided in the prescribed manner by the Insurance Commissioners." The matter is one of importance to medical men on the panel, many of whom would no doubt prefer trifling or vexatious disputes between them and their patients to be decided without recourse to courts of law, while it is also a matter to be considered that reluctance to set the law in motion in support of a bad case may operate to protect medical men on the panel to some extent against frivolous attacks, which might more easily be made in the form of a complaint to an Insurance Committee. In view of an appeal possibly taking place the applicability of the subsection and the scope claimed for it are not discussed here; but it is to be hoped that if the divisional court decides in the defendant's favour a pronouncement will be made as to precisely what kind of claims are excluded from the ordinary legal remedy, and whether claims for alleged negligent treatment are on the same footing as those based upon the medical man's failure to attend. If the result of an appeal should be against the construction which the defendant in the case referred to has sought to place upon Section 67, Subsection 2, the medical profession will have to consider whether it should press for an amendment of the Act which will enable all alleged shortcomings of practitioners under the Act to be dealt with by Insurance Committees, to the exclusion of other tribunals. It must be remembered, however, that any inquiry so held will necessitate the calling of witnesses on both sides, just as much as if the investigation were before a court of law, and the question of whether their evidence should be taken on oath must also be considered. It must also be remembered that in the case under discussion damages were claimed and awarded.

THE STATISTICS OF INSURANCE IN SCOTLAND.

In Scotland the total number of insured persons made up to April 9th was 1,492 527, of whom 1,462.509 were members of Approved Societies, 30,016 were deposit contributors, and 2 belonged to the Navy and Army Insurance Fund. Of those belonging to Approved Societies 616,738 were in the areas of County Insurance Committees and 845,771 in the areas of Burgh Insurance Committees, the corresponding figures for deposit contributors being 13,605 and 16,411.

CHELSEA CLINICAL SOCIETY.—The opening meeting of the seventeenth session of this society will be held on Tuesday, Oct. 21st, at St. George's Hospital, in the club-rooms of the medical school, at 8 30 P.M., the President, Dr. T. B. Hyslop, in the chair. Dr. Hyslop will give an opening address, and has chosen as his subject "Clinical Psychiatry." Dr. Kenneth E. Eckenstein, 8, Bentinck-street, W., and Dr. J. Campbell McClure, 41, Welbeck-street, W., are the honorary secretaries of the society.

THE SLAUGHTER-HOUSES OF CHARD (SOMERSET).—At the last meeting of the Chard town council the medical officer of health, Mr. W. Mence, reported that he had inspected the slaughter-houses of the town, and he found them in a fairly dirty condition. The premises were dirty, and the bins and receptacles which contained the offal, intestines, &c., were full of decaying animal matter and covered with flies. The medical officer desired the council, before the licences were renewed, to request the owners to carry out certain alterations. After some discussion it was decided to carry out Mr. Mence's recommendations forthwith.

Medical News.

Weibel has been recognised as *privat-docent* of Midwifery and Gynæcology.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL (UNIVERSITY OF LONDON).—The following scholarships have been awarded as the result of recent examinations held in connexion with this school:—Medical Entrance Scholarships (for those commencing medical studies): Science (£50), H. O. Gunewardene; Arts (£50), A. Blackstock. Medical Entrance Scholarships (for those commencing their final medical studies): (*a*) Anatomy and Physiology (£50), Wilfred Wood and H. A. B. Whitelocke; (*b*) General and Clinical Pathology and Pharmacology (£50), E. C. Malden.

THE LOCAL GOVERNMENT BOARD AND THE SALARIES OF POOR-LAW MEDICAL OFFICERS.—At the last meeting of the Bridgwater board of guardians the question of the reduction of the salary of the workhouse medical officer came under discussion. Eventually the clerk read a communication from the Local Government Board stating that in reply to the letter of the guardians relative to their proposal to reduce the salary of the workhouse medical officer from £65 to £54 per annum, "the Local Government Board would point out that the guardians are *not* empowered to reduce the salary of the medical officer without his consent."

LONDON AMBULANCE SERVICE.—At the meeting of the London County Council on Oct. 14th Mr. E. Smallwood drew attention to the case of a school teacher who was taken ill in the street in Stoke Newington and conveyed on a costermonger's barrow to a hospital, where she died a few hours later. Could any indication be given, he asked, as to the early removal of the reproach to London caused by the absence of an efficient ambulance service.—Mr. Ernest Gray, chairman of the General Purposes Committee, said he was glad to be able to state that Parliament had granted the powers whereby the Council might coördinate the ambulance services of London. Under those powers he hoped that an efficient ambulance service would be provided for the whole of London before the end of the present year.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on Oct. 9th, Sir Francis H. Champneys being in the chair. A letter was considered from the Clerk of the Council transmitting a copy of a letter from the National Health Insurance Commissioners (England) on the subject of the effect of the working of the Insurance Act on the administration of the Midwives Act. The Board directed that the Privy Council be thanked for its communication. A letter was considered from the Local Government Board transmitting a copy of a communication from the guardians of the Romford Union relative to their application for the recognition of their medical officer as a teacher of pupil midwives, and asking for the Board's observations thereon. The Board decided that the letter drafted by the chairman be approved and forwarded to the Local Government Board. Letters were considered from the deputy coroner for the West Riding of Yorkshire calling the attention of the Board to the fact that premature birth is not one of the cases specifically mentioned in the rules as imposing on a midwife the obligation of advising medical assistance, and asking the views of the Board on the subject; and from the clerk of the Derbyshire county council suggesting that a rule should be

framed under which midwives would automatically cease to be enrolled on attaining the age of 70. The Board directed that the deputy coroner for the West Riding of Yorkshire and the clerk of the Derbyshire county council be thanked for their suggestions, which will be considered at the next revision of the rules.

LITERARY INTELLIGENCE.—Messrs. George Routledge and Sons, Limited, announce for early publication "A Handbook of Photomicrography," by H. Lloyd Hind, B.Sc., F.I.C., and W. Brough Randles, B.Sc. The new work will contain an account, with illustrations, of the modern methods employed in photomicrography, with a description of the apparatus and processes, treated both from a microscopic and photographic point of view.

NORTH-EAST LONDON POST-GRADUATE COLLEGE.—The opening address of the winter session will be delivered by Sir W. Arbuthnot Lane, Bart., at the Prince of Wales's General Hospital, Tottenham, N., on Thursday, Oct. 23rd, at 4.30 P.M., the subject being "Intestinal Stasis." In illustration of the address, and for the first time, some 20 cases that have been operated on for this condition will be shown. Professor Pouchet, of Paris, is coming to London with a number of leading French physicians especially to hear the address. Dr. W. Seaman Bainbridge, of New York, will give a supplementary demonstration on the subject, and Dr. A. C. Jordan will show some X ray photographs with the lantern. Any medical practitioner wishing to attend will be welcomed if he will apply by letter to the Dean of the College, at the Hospital, for a card of admission.

THE LIBRARY OF THE SOCIETY OF APOTHECARIES.

LOVERS of old books will delight in the Catalogue of the Library of the Society of Apothecaries, by Willam Bramley Taylor, Master of the Society and honorary librarian, edited by J. E. Harting (London: Taylor Brothers. 1913. Pp. 102). The library, indeed, makes no pretence of being an up-to-date scientific library for the use of the modern student; it is rather a collection of old books gathered together during many years. It appears to have had its origin, according to the archives of the society, on Nov. 28th, 1633, when Mr. Thomas Johnson, of Snow Hill, presented to the society "as a guifte, a booke called *Gerard's Herbal*." It seems safe to identify the donor, who, by the way, according to Barrett, was made free of the Livery and presented with a gown and hood in return therefor, with the Thomas Johnson who in 1633 brought out the second edition of "The Herball; or General History of Plantes, gathered by John Gerarde of London, Master in Chirurgie," which was originally published in 1597. The library at present contains a copy of Johnson's edition (as well as one of the original), but it cannot be the same, for in 1666 the Apothecaries' Hall perished in the Great Fire, and doubtless all the books with it. However, in 1681 a new library was begun, connected with the "Physic Garden" at Chelsea, which received in 1739 a notable addition in the collection of books and dried plants bequeathed by Dr. Samuel Dale, of Braintree, Essex, and including the collection of Mr. John Ray. Meantime deep cupboards on either side of the fireplace of the gallery of the Hall were used as a repository for the new library that was being formed in the Hall, and in 1744 the present book-cases were constructed. About 1832 the books from the Physic Garden, 218 in number, were transferred to the Hall library, which at the present time contains about 1700 volumes and 43 periodicals. A cursory perusal of the Catalogue brings out the fact that the great bulk of the books date between the end of the fifteenth century and the end of the eighteenth. There is a goodly sprinkling also of books of the first quarter of the nineteenth century, a small number from the second quarter, and only three or four of later date than 1850. As might be expected, they are mainly connected with materia medica, and more especially plants, though medicine and surgery and their branches and the collateral sciences are fairly represented, and medical history and biography are to be found. A few incongruous volumes break the uniformity in subject matter. A Greek and Latin lexicon may be regarded as a medical necessity, and works on gardening are well in place. Agriculture is, perhaps, a step further removed, and the "Plans of Capital Cities" (1771) seems even more remote, but "Bell's British Theatre: consisting of the most esteemed English plays, Vols. 1–21, London, 1777–80," suggests a votive offering from some play-actor, who thus showed a gratitude he could not express in the more usual manner. Naturally the library is rich in herbals and pharmacopœias. The following is a list of the former: Brunfels, 1530; Clusius, 1601; Coles, 1657; Culpepper, 1651; Dodoens, 1578; Durante, 1585; Fuchs, 1542; Gerard, 1597 and 1633; Hudson, 1762; Johnson, 1633; Lovell, 1659; Lyte, 1578 and 1595; Pancovius, 1654; Parkinson, 1629 and 1640; Tournefort, 1719; and Turner, 1551. Among the pharmacopœias are those of the United States of America, 1830 and 1840; Argentoratum, 1725; Bavaria, 1688; Berlin, 1698; Brussels, 1837; Dublin, 1826; Edinburgh, 1744, 1774, 1783, 1792, 1795, 1803, 1805, and 1839; Lisbon, 1784–94; London, 1650, 1677, 1689, 1711, 1721, 1724, 1744, 1746, 1747, 1763, 1786, 1787, 1788, 1791, 1793, 1815, 1824, 1836, and 1851; Guy's, 1818 and 1837; Conspectus of Pharmacopœias, 1847; Paris, 1758, 1818, and 1837; Radcliffe, 1716; and Russian, 1782.

SEXUAL TEMPERAMENT.

To the Editor of THE LANCET.

SIR,—Mr. Victor Bonney, in an enlightening contribution on artificial vagina in your issue of Oct. 11th, refers to the absence of sexual feeling on the part of one of the cases. Can any reader inform me approximately what is the proportion of English married women who fail in this quality? Is there any authoritative information on this point? The percentage of American women has been stated on fair authority to be very high.

I am, Sir, yours faithfully,

Oct. 13th, 1913. M.A., M.B. Cantab.

CLIMATE AND HEALTH OF MUSCAT.

Major Knox, H.M. Consul at Muscat, observes in his annual report that although that town is frequently described as one of the hottest in the world it cannot be said to be unhealthy. During 1912–13 the highest temperature recorded was 114° F. and the lowest 64°. The high temperature was due to the hot winds, which at certain times in the summer months, and generally only for a few hours at night, blow from the Arabian deserts and barren rocks round Muscat. For the greater part of the summer, owing to the high state of humidity of the atmosphere in combination with a high temperature, the climate is very trying. From November till the middle or end of March the weather is distinctly pleasant, but fails to be bracing, as the temperature seldom falls below 60°. The rainfall averages four inches only, and it is due to this fact that Muscat may be considered a fairly healthy tropical port, provided ordinary precautions are taken to purify the drinking-water by boiling or filtration, and to protect oneself from mosquitoes, which during the winter months are numerous in the town, and the cause of a considerable amount of malaria amongst natives. There were no cases of cholera, small pox, or plague during the year, and only a few cases of dysentery and enteric fever amongst the native population. Muscat is the capital and the principal port of the Sultanate of Oman, which comprises a portion of the south-eastern coast of Arabia up to the entrance to the Persian Gulf. Muscat is the only port of call for steamers in Oman, but as the town lies at the end of a cove surrounded by huge rocky hills it has no means of communication with the interior. The neighbouring town of Matrah, about two miles up the coast, supplies this want, and is the local centre for trade with the interior. The population of Muscat is about 10,000 and of Matrah about 14,000. Neither of these towns makes any pretence of sanitation. Muscat presents a picturesque appearance from the sea, but the interior of the town is for the most part mean and squalid. Matrah is, if anything, worse than Muscat. The interior of Oman is mountainous, and the inhabitants, for the most part, are poor. The population is estimated at about 500,000, of whom a considerable portion are nomadic.

THE INDIAN CIVIL SURGEON OF THE PAST.

To the Editor of THE LANCET.

SIR,—At page 1100 of THE LANCET of Oct. 11th you publish a description of the "Indian Civil Surgeon of the Past," as stated by the *Indian Planter's Gazette*. I have not the opportunity of seeing the original, but should be greatly surprised if the quotation you give from that paper was seriously meant to contrast past with present conditions of the Indian Medical Service, which was, and is, the chief source of supply of civil surgeons.

The words you quote from the *Indian Planter's Gazette* are from "Twenty-one Days in India," by George Aberigh Mackay, one of the most splendid instances of sarcastic and yet withal kindly and humorous, and at times pathetic, productions I have ever read. It would, however, be just as correct to accept Mark Twain's description of the "undertaker" who manipulated faces of departed husbands that they might wear the *risus sardonicus* as typical of the methods of that doctor's ally, as to hold that in 1880, when Mackay wrote "The Civil Surgeon," he dealt with other than fiction.

Without vouching for the accuracy of my information, I have been told that Mackay realised his wish of being free from the attentions of the loud civil surgeon he typifies by dying whilst on a journey before medical aid could be secured for him.

I am, Sir, yours faithfully,

W. G. KING, Colonel I.M.S. (retired).

Hatch End, Oct. 12th, 1913.

MALARIA AND SMALL-POX IN SIAM.

IN a report to the Foreign Office Mr. T. H. Lyle, British Consul at Chiengmai, the second town of importance in Siam, mentions that an epidemic of malignant malaria, which commenced in 1911, continued unabated during 1912, but in June of the present year (the time of the writing of the report) an improvement had set in. The disease moved slowly from village to village, and assumed a curiously localised form, in that one district would be attacked whilst other districts in the immediate neighbourhood would remain for a time entirely unaffected. Small-pox also prevailed in epidemic form until nearly the end of 1912. Vaccination was rigorously carried on, both by the Siamese Government and by the American Presbyterian Mission, over 50,000 successful cases being recorded by the latter. The leper asylum, constructed a few miles south of Chiengmai by the efforts of the medical representative of the American Presbyterian Mission, continues to attract sufferers from all parts of the country, one inmate having sought this refuge from a remote district in British territory. The Siamese Government continues to show a sympathetic and practical interest in this good work. The leper patients have increased from 27 in 1910 to 100 in 1913. For the year ended March, 1911, the population of the Chiengmai district was returned at 1,223,761, but it is now estimated at only 1,189,431. The recent two years' epidemics of small-pox and malignant malaria cannot fail to have had serious effects, more especially amongst infants and very old people.

"LEAD-POISONING."

To the Editor of THE LANCET.

SIR,—A man who had been sitting on the damp grass for some hours writing with a lead-pencil and frequently sucking the point thereof while waiting for inspiration, eventually felt a sharp pain in his loins. He limped to a local quack. After questioning him as to the onset of the attack, the quack simply said "plumbism." The man received some yellow pills, paid the fee, and went away. He was a studious person and

searched the encyclopædia for the meaning of "plumbism" and what lead-pencils were made of. The next day he returned to the quack and said, "You told me I had 'plumbism,' which is lead-poisoning, and I now find there is no lead in lead-pencils, only graphite or plumbago." "Oh," replied the quack airily, "did I say plumbism is the cause of your lumbism? I meant to have said plumbago is the cause of your lumbago." "Oh," said the man, "but anyhow, your pills are only bread." "Of course, of course," replied the quack, "don't you know that bread is the oldest and finest thing to remove pencil marks with? You didn't want me to give you indiarubber pills, did you?"

I am, Sir, yours faithfully,

J. MILLER.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY.

SPECIAL MEETING OF FELLOWS: at 5.30 P.M. (Postponed from last Monday.)

Demonstration by Dr. Hideyo Noguchi of the Rockefeller Institute.

(1) Pure Cultures of Various Spirochætæ (Treponema pallidum, T. pertenue, T. microdentium, T. macrodentium, T. mucosum, T. calligyrum, T. refringens).
(2) Transmission of Syphilis to Animals by means of Pure Cultures of Treponema pallidum.
(3) Demonstration of Treponema pallidum in the Brain of General Paralytics.
(4) Transmission of Treponema pallidum from the Brain of General Paralytics to the Rabbit.
(5) Production of Symptoms and Lesions resembling General Paralysis in the Rabbit by means of an Intracerebral or Subdural Inoculation with Treponema pallidum.
(6) Cultural Studies of the Virus of Rabies.

Illustrated by Lantern Slides.

TUESDAY.

SECTION OF THERAPEUTICS AND PHARMACOLOGY (Hon. Secretaries: W. Langdon Brown, Philip Hamill): at 4.30 P.M.

Discussion:

On Diseases Due to Deficiencies in Diet, opened by Dr. F. G. Hopkins, F.R.S.

The following will take part in the discussion:—Dr. Robert Hutchison, Dr. Casimir Funk, Dr. F. M. Sandwith.

Fellows wishing to take part are requested to communicate with the Hon. Secretaries.

SECTION OF PATHOLOGY (Hon. Secretaries—Gordon W. Goodhart, C. Price-Jones): at 8.30 P.M.

Presidential Address:

Dr. F. W. Andrewes.

THURSDAY.

SECTION OF BALNEOLOGY AND CLIMATOLOGY (Hon. Secretaries—Chas. W. Buckley, J. Campbell McClure): at 5.30 P.M.

Presidential Address:

Dr. F. A. de T. Mouillot: Some Lessons derived from Twenty Years of Spa Practice.

The Annual Dinner will be held at 7.15 P.M., the same evening at the Waldorf Hotel, and the following are expected as guests of the Section:—Sir Malcolm Morris, Sir Philip Magnus, and Dr. A. Manuel.

FRIDAY.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—F. Langmead, Philip Turner, William J. Midelton): at 4.30 P.M.

Cases:

Dr. C. E. Zundel: (1) Infantilism associated with Diabetes Insipidus; (2) Infantilism associated with Albuminuria.
Dr. E. A. Cockayne: (1) Constriction of Arm by Amniotic Bands; (2) Hemiplegia with Very Extensive Nævus in a Baby.
Dr. J. Porter Parkinson: Rheumatoid Arthritis in a Boy.
Dr. T. R. Whipham: (1) Three Cases of Under-development; (2) Enlarged Liver and Spleen associated with Jaundice.
Dr. F. Langmead: (1) Cretinism in a Baby; (2) Two Sisters with Deformity of Bones and Splenomegaly.

Pathological Specimens:

Dr. J. Porter Parkinson: New Growth in the Small Intestine.
Dr. J. D. Rolleston: Diphtheria of the Trachea and Bronchi.

SECTION OF EPIDEMIOLOGY AND STATE MEDICINE (Hon. Secretaries—G. S. Buchanan, William Butler): at 8.30 P.M.

Paper:

Dr. W. M. C. Wanklyn: Working-class Home Conditions in London.

LONDON DERMATOLOGICAL SOCIETY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY.—4.30 P.M., Demonstration of Living Spirochætæ and other Microscopic Specimens. Cultures and Preparations of Sporothrix. Cases sent for Consultation. Clinical Cases by Dr. M. Dockrell, Dr. Bunch, Dr. K. Sibley, Dr. W. Griffith, and Dr. J. L. Phibbs. 5.15 P.M., Discussion on Some Methods of Treating Syphilis (opened by Dr. J. L. Bunch).

CHELSEA CLINICAL SOCIETY, Club Rooms of the Medical School, St. George's Hospital, S.W.

TUESDAY.—8.30 P.M., Opening Address:—Dr. T. B. Hyslop (President): Clinical Psychiatry.

MEDICO-LEGAL SOCIETY, 11, Chandos-street, Cavendish-square, W.

TUESDAY.—8.30 P.M., Mr. A. S. Morley: Injuries of the Back, Considered from their Medico-Legal Aspect.

HUNTERIAN SOCIETY, St. Bartholomew's Hospital (Library), E.C.

WEDNESDAY.—9 P.M., Address:—The President (Dr. W. M. Ettles). Dr. A. S. Woodwark will show a series of Pathological Specimens recently added to the Museum of St. Bartholomew's Hospital.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY.—5 P.M., Mr. Shattock: Specimens illustrating Fibroma. (Museum Demonstration.)
WEDNESDAY.—5.30 P.M., Mr. Colyer: Specimens illustrating Irregularities of the Teeth in Animals. (Museum Demonstration.)
FRIDAY.—5 P.M., Prof. Keith: Specimens illustrating Anatomical and Pathological Conditions of the Great Bowel in Cases of Intestinal Stasis. (Museum Demonstration.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. J. Galloway: Clinique (Skin). 5.15 P.M., Lecture:—Dr. J. H. Sequeira: Common Errors in Diagnosis—The Skin.
TUESDAY.—4 P.M., Dr. G. A. Sutherland: Clinique (Medical). 5.15 P.M., Lecture:—Dr. F. J. Smith: Common Errors in Diagnosis—How to Avoid Them.
WEDNESDAY.—4 P.M., Mr. D. C. L. Fitzwilliams: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. E. Clarke: Common Errors in Diagnosis—The Eye.
THURSDAY.—4 P.M., Dr. W. J. Fenton: Clinique (Medical). 5.15 P.M., Lecture:—Dr. D. Grant: Common Errors in Diagnosis—The Throat.
FRIDAY.—4 P.M., Mr. S. Stephenson: Clinique (Eye). 5.15 P.M., Lecture:—Dr. W. Wingrave: Common Errors in Diagnosis—Clinical Pathology.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. Bernstein: Blood.
TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin. 5 P.M., Lecture:—Dr. Davis: Diseases of Throat, Nose, and Ear.
WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 11 A.M., Mr. Souttar: Demonstration of Minor Operations. 12 noon, Lecture:—Mr. Souttar: Abdominal Diagnosis. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Mr. H. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Dr. Bernstein: Blood.
THURSDAY.—10.30 A.M., Dr. Simson: Gynæcological Demonstration. 12.15 P.M., Lecture:—Dr. G. Stewart: Neurological Cases. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. Bernstein: Blood.
FRIDAY.—Annual Meeting of Ladies' Association. College closed.
SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 12 noon, Lecture:—Mr. Souttar: Surgical Anatomy of the Abdomen. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—Out-patient Demonstrations:—10 A.M. Dr. Singer: Medical. Mr. H. Curtis: Surgical. 12 noon, Mr. G. N. Biggs: Throat, Nose, and Ear.—2.15 P.M., Mr. W. Turner: Surgery. 3 P.M., Mr. W. Turner: Operations. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.15 P.M., Mr. R. Lake: Ear and Throat.
TUESDAY.—Out-patient Demonstrations:—10 A.M., Dr. G. Holmes: Medical. Mr. Cole: Surgical. 12 noon, Dr. H. MacCormac: Skin.—2 P.M., Mr. L. McGavin: Operations. 2.15 P.M., Mr. R. Carling: Surgery. 3.15 P.M., Dr. G. Rankin: Medicine.
WEDNESDAY.—Out-patient Demonstrations: 10 A.M., Dr. F. Langmead: Medical. Mr. C. Rowntree: Surgical. 11 A.M., Mr. R. E. Bickerton: Eye.—2 P.M., Mr. L. V. Cargill or Mr. Choyce: Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.15 P.M., Mr. Cargill: Eye Clinique. 4.30 P.M., Mr. C. C. Choyce: Surgery.
THURSDAY.—Out-patient Demonstrations:—10 A.M., Dr. Singer: Medical. Mr. H. Curtis: Surgical. 12 noon, Mr. G. N. Biggs: Throat, Nose, and Ear.—2 P.M., Mr. R. Carling or Mr. W. Turner: Operations. Dr. A. Davies: Pathological Demonstration. 3.15 P.M., Dr. R. Wells: Medicine. 4.30 P.M., Special Lecture:—Dr. R. O. Moon: Heart Strain.
FRIDAY.—Out-patient Demonstrations;—10 A.M., Dr. G. Holmes: Medical. Mr. Cole: Surgical. 12 noon, Dr. H. MacCormac: Skin.—2 P.M., Mr. L. McGavin: Operations. 2.15 P.M., Sir John Rose Bradford; Medicine. 3.15 P.M., Mr. L. McGavin: Surgery.
SATURDAY.—Out-patient Demonstrations: 10 A.M., Dr. F. Langmead: Medical. Mr. C. Rowntree: Surgical. 11 A.M., Mr. R. E. Bickerton: Eye.—10 A.M., Col. Barry: Radiography.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

THURSDAY.—4.30 P.M., Opening Address:—Sir Arbuthnot Lane, Bart.: Intestinal Stasis (illustrated by lantern slides and the exhibition of patients).

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON), Clinical Theatre, London Hospital, Mile End-road, E.

Course of Lectures on the Neuroses and Psychoses of Children:—

TUESDAY.—2 P.M., Dr. F. Warner: Development of the Infant Brain.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Mr. P. Sargent: Posterior Root Section.

FRIDAY.—3.30 P.M., Clinical Lecture:—Mr. P. Sargent: Cerebral Decompression.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

TUESDAY.—6 P.M., Dr. K. Sibley: Alopecia.

THURSDAY.—6 P.M., Dr. M. Dockrell: Eczema (its Varities, Symptoms, and Treatment).

MANCHESTER HOSPITALS POST-GRADUATE CLINIC.

TUESDAY.—SALFORD ROYAL HOSPITAL—4.30 P.M., Mr. G. Wright: Intestinal Stasis.

WEDNESDAY.—ROYAL INFIRMARY—4.30 P.M., Mr. J. W. Smith: Appendicular Dyspepsia.

THURSDAY.—ANCOATS HOSPITAL—4.30 P.M., Dr. D. E. Core: Hæmoptysis.

FRIDAY.—ROYAL EYE HOSPITAL—4.30 P.M., Dr. J. Wharton: Shadow and Vessel Test.

ROTUNDA HOSPITAL POST-GRADUATE COURSES, Dublin.

MONDAY.—10 A.M., Obstetrical Lecture: The Phenomena of Labour. 11 A.M., Examination of Patients and Minor Operations.

TUESDAY.—10 A.M., Major Operations.

WEDNESDAY.—10 A.M., Obstetrical Lecture: The Phenomena of the Puerperium. 11 A.M., Examination of Patients and Minor Operations.

THURSDAY.—10 A.M., Major Operations.

FRIDAY.—10 A.M., Gynæcological Lecture: Operating on the Fallopian Tubes. 11 A.M., Examination of Patients and Minor Operations.

For further particulars of the above Lectures, &c., see Advertisement Pages.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced:—

April 26th–Nov. 5th (Ghent).—International Exhibition.

May 31st to October (London, Earl's Court).—Imperial Services Exhibition.

May–October (Leipzig).—First International Building Exhibition.

June 24th–Oct. 31st (London, 54a, Wigmore-street).—Historical Medical Museum. (Organised by Mr. Henry S. Wellcome.)

June–October (London, Crystal Palace).—Anglo-German Exhibition.

Oct. 1st–Nov. 1st (London, Shepherd's Bush).—National Gas Exhibition.

,, 9th–25th (London, Olympia).—Ideal Home Exhibition.

,, 22nd–25th (Berlin).—Eleventh International Anti-Tuberculosis Conference.

,, 28th–Nov. 1st (London, Royal Horticultural Hall).—Twenty-fourth Universal Cookery and Food Exhibition.

Nov. 7th–15th (London, Olympia).—Twelfth International Motor Exhibition.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial Staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

An Introductory Lecture

ON

THE CAUSES AND SYMPTOMATOLOGY OF IMPAIRED RETINAL ACTIVITY.

Delivered at the Royal Eye Hospital, London, on Oct. 13th, 1913,

BY GEORGE A. BERRY, M.B. EDIN., LL.D., V.P.R.C.S. EDIN.,

HONORARY SURGEON OCULIST TO H.M. THE KING IN SCOTLAND; CONSULTING OPHTHALMIC SURGEON, ROYAL INFIRMARY, EDINBURGH, ETC.

GENTLEMEN,—The functions of the retina and its nerve continuations, including the centre for vision in the brain, are customarily and conveniently considered in relation to three subdivisions of the sense of sight. These are: (1) the light sense—the sense of light intensity; (2) the colour sense—the sense of the quality of any light impression; and (3) the form sense—or the sense by which we discriminate between any quantitative or qualitative differences in the contiguous impressions which are made within the area occupied by the image on the retina of any external object. A distinction has also to be drawn between the foveal or central, and the more rudimentary excentric, vision.

In order that we may be able to draw inferences which may be helpful both in diagnosis and prognosis it is important to have some notion of the normal interrelations of these three divisions of the sense of sight, and of the nature of deviations from the normal associations. This is often not sufficiently kept in view. Much information which it is possible to derive from subjective examination alone is comparatively seldom looked for. Except in the case of optical defects it is rare that any attention is given to why, and in what way, different abnormal conditions cause a loss of retinal activity. I propose in this lecture to discuss some physiological facts connected with vision, to draw some inferences from these facts, and to refer more particularly to subjective methods of examination. I shall also discuss the conditions of the whole visual apparatus upon which they are capable of throwing light. Although, in doing so, it will be necessary to refer to the more purely scientific aspects of the subject, I shall mainly lay stress on the practical applications of the tests, and the practical conclusions to which what may be called an extended, more complete, subjective examination leads. In doing so, although I may go over ground with which you are familiar, I hope to bring before you some points of view with which you are perhaps not so fully acquainted.

THE FORM SENSE.

To begin with the form sense: it is the estimate of this sense that we make in the ordinary test for visual acuteness. The measure of acuteness is the measure of the degree to which it is possible to discriminate as separate impressions contiguous excitations of the retina which differ in intensity or quality. For the ordinary tests, Snellen's types, the contrast between the letters and their background is, practically speaking, a maximum—black on white. When these types are recognised at a distance for which the edges of the white interspace between two black figures subtend an angle with the eye of not more than 1′ the acuteness of vision is taken as coming up to the normal standard. This, however, though representing practically normal acuteness, is not necessarily the greatest acuteness of which the eye tested is capable.

The usual test for visual acuteness is made in a good light, as the object of the test is to determine the acuteness in ordinary daylight. Every day observation shows us that the vision is less sharp in a bad light. The more feeble the illumination the greater is the diminution in acuteness. On the other hand, the acuteness is heightened if the intensity of the illumination is increased to beyond that of ordinary daylight, until a point is reached when it again diminishes as the intensity is still further increased. Approximately it is found that to increase of intensity in geometrical progression there corresponds increase in acuteness in arithmetical progression up to the point from which acuteness ceases to increase, and beyond which it decreases as the intensity is increased.

The test with Snellen's types not only implies that the letters are capable of being distinguished when their characteristic parts subtend an angle of 1′, but that they are distinguishable when the parts subtending that angle form part of a letter whose height and breadth subtend angles of 5′.

Though Snellen's types constitute the most convenient, most practical, means of determining the acuteness of direct vision, and notwithstanding the existence of many rival tests they are the most universally adopted, we do not by their use arrive at any mathematically accurate measurement of acuteness. It is well to remember that the various letters of the test are by no means equally distinguishable. A letter of Snellen's types can often be recognised at a distance for which simpler figures which subtend the same visual angle are not recognisable. The easiest letters to distinguish are A, L, and T. Of those apt to be mistaken for each other are V with Y, or U and O with C and G, and F with P. Thus in testing we may find, where the acuteness is not normal, that immediately below a line of test types in which all the letters are recognised, there come one or two in which some letters only, or one letter only, can be deciphered. Again, where we find the acuteness considerably greater than 6/6, this is not always, or even generally, the case for all the letters, but only for those whose shape as a whole exerts an influence on their legibility.

Anatomical and Physiological Considerations.

We may now consider what are the anatomical and physiological facts which justify the generally accepted inference that the form sense is dependent upon the stimulation by light of the layer of rods and cones of the retina. So far as anatomy goes the points that are suggestive are: the fact that these organs constitute the extreme end of the nerve chain, that they are arranged normally to the surface of the retina, that their ends have a mosaic-like arrangement, and, lastly, that their size is consistent with their supposed function. And considered from a physiological standpoint: as it is found that a number of closely contiguous yet discrete luminous points, whose optical images are sharply focused, can also be seen as separate points, it follows that the layer of the retina in which the light stimulus causes a nerve response must have a mosaic-like arrangement. Each element in this layer must consequently have no considerable size in a direction tangential to the surface, and it is hardly possible to imagine a superposed arrangement of stimulable elements. There must only be one sensitive element placed normally to the retina at each point, as there is only one distinguishable sensation caused from each point. The layer of rods and cones not only answers to these various requirements but is the only layer of the retina which does so.

A further deduction which has to be made is that, for the fovea at any rate, each single element of the stimulable layer must have a sufficiently isolated connexion with its nerve continuation by which its stimulation leads to a conduction to the visual centre. It is only thus, in fact, that two contiguous end-organs, which are subjected to different degrees of stimulation, can be supposed to elicit impressions that are separately distinguishable. It is only thus, therefore, that can be explained the fact that two equally bright external objects are capable of causing separate impressions when their retinal images are separated from each other by a space not greater than corresponds to the breadth of a single end-organ. The correspondence in size between the smallest distinguishable separation of retinal image points and that of the cross section of the retinal cones is very close. Both are approximately equal to from 1/250 mm. to 1/200 mm. Theoretically the former might be even a little less than the latter.

It is rather remarkable that the correspondence should be so close, because even the most perfectly focused retinal image does not anywhere nearly comply with what might at first sight be supposed to be the conditions which would permit of so great a possible visual acuteness. For it never is the case that light emitted or reflected from any external object leads to a stimulation of two end-organs only, which are separated by not more than one other end-organ. Owing to the necessarily imperfect focusing, which is owing principally to chromatic aberration, the intervening end-organ is

also always stimulated at the same time, though not to the same extent. The image of any external point of light is always diffuse and not absolutely sharp. Its diffusion extends, given a pupil of moderate size, over an area which is 80 to 100 times as great as that occupied by the transverse section of a cone. It is only because the intensities of the stimulation over this diffusion area diminish rapidly from centre to periphery, as well no doubt because of the mosaic-like arrangement of the sensitive layer, that the distinguishing power of the eye can reach the degree which it is actually found to do, and thus come to correspond as nearly as it does to its conceivable maximum. It is of importance to remember the existence of this diffusion of an image of a point as it explains many of the phenomena of vision.

Notwithstanding that the intensity of illumination has so great an effect on acuteness of sight, this is counteracted by an influence of great importance. Owing to the power of adaptation to light which exists in the percipient parts of the eye—the adaptation of the retina—there may be, within very wide limits of illumination, but little appreciable change in acuteness. But as adaptation takes place comparatively slowly any sudden change of illumination of sufficient amount causes either an increase or a diminution of acuteness according to the direction of the change.

Retinal adaptation is an important factor to take into consideration, as it does not always take place with the same rapidity or to the same extent in different individuals. It may happen that individuals with equally good, or normal, acuteness in full daylight have by no means equally sharp sight under a comparatively feeble illumination. There may, too, be little, if any, difference in the acuteness of two individuals caused by a sudden change, and yet be a marked difference between them when the change has been slow and has thus given time for a normal adaptation to take place. A defect in the range of possible adaptation may be either congenital or acquired. When the defect is marked it gives rise to what is called twilight-blindness or night-blindness, which may be met with in very varying degrees. In the lesser degrees it has not usually any pathological significance. It is common enough to meet with people, especially myopes, who throughout life see quite decidedly worse in the dark than others, but whose sight remains otherwise normal. The more marked degrees of night-blindness, however, are attributable to actual pathological changes which must be looked for in that part of the eye in which adaptation takes place. That this is mainly, if not entirely, in the hexagonal retinal cells is an inference which is forced upon one by facts of both physiology and pathology.

But, in addition to the influence of the absolute brightness of objects seen, it is obvious that differences in contrast —i.e., variations in the extent to which the different parts of objects differ in brightness—must also have an effect on the sharpness of sight. With the exception of print, where there is the full contrast of black on white, most objects are not presented to the eye with the same contrast in their details.

Factors determining Visibility.

The visibility, therefore, of any object depends upon four circumstances: (1) the visual angle under which it is seen; (2) the degree of its illumination; (3) the difference between its own brightness, and (4) its own colour, and that of its background. And it is found that a difference in brightness must attain a certain degree before it becomes appreciable. Bjerrum seems to have been the first to investigate the effect of degrees of light contrast on visual acuteness, and more particularly to show the importance of contrast from a practical clinical point of view.

A thorough subjective test in any case of defective vision entails an estimation of the existing acuteness of sight under different degrees both of illumination and of contrast.

THE LIGHT SENSE.

We may now consider the light sense a little more fully. By that sense, apart from its necessary relation to the sense of form, is understood the power which the eye has of distinguishing differences in light intensities. This, of course, includes the power of distinguishing light from darkness. It is customary, however, and also clinically useful, to differentiate between the acuteness of the sense of appreciating light from darkness—what is usually then spoken of as the *light minimum* sense—and the acuteness in distinguishing between light impressions of different intensities or the *light difference* sense.

From a scientific point of view the best method of measuring the acuteness of these two constituents of the light sense are for the former Förster's photometer and for the latter Masson's disc. For clinical purposes, however, it is more convenient not to attempt any accurate measurement of the light sense as dissociated from the sense of form.

The Mechanism of Retinal Stimulation by Light Vibrations.

We have already considered the causal connexion between the form sense and the stimulation of the retinal cones, but we have not yet discussed the mechanism of their stimulation by light vibrations. It is known that there is no direct action of light on the nerve elements of the retina of which the rods and cones are the terminals. In fact, it is not light vibrations alone which may cause luminous sensations. The light sensations caused by pressure on the eye—what are known as phosphenes—afford an indication that a retinal activity can be aroused mechanically, and the fact that phosphenes are light in the dark, and dark when the eye is exposed to light shows that pressure not only causes a stimulation but also diminishes the excitability of the retina for the normal stimulus of light vibrations.

Light vibrations produce their stimulation therefore indirectly. They set up in the first place some physico-chemical change in the contents of the hexagonal pigment cells. This change then excites the functional activity of the nerve fibres through their terminals the rods and cones. One result of the indirect nature of the stimulation is that a measurable amount of time elapses before an excitation causes its full impression, and also before, on the cessation of the action of the physical excitant, the impression altogether ceases and disappears. It is for this reason that separate stimulations which succeed each other with sufficient rapidity give rise to continuous visual impressions.

The nature and strength of the impression caused by light rays passing to the eye from an external object are therefore influenced by the following conditions: the size of the pupil, the supply of chemical material in the retinal pigment cells, the stimulability of the nerve elements of the retina, the conductivity of the optic nerve fibres, and the receptivity of the cells in the visual centre. The hexagonal pigment cells and the nerve end-organs in the retina are therefore mutually suppporting and associated in the process of converting the physical cause into the physiological sensation of light. Without the pigment cells the nerve endings would not respond to ether vibrations, and without the nerve elements the physico-chemical changes which these vibrations set up in the substance of the cells could not lead to conscious light impressions.

Now we find a distribution of the pigment cells over the whole extent of the functionally active portion of the retina. It is true that some little difference exists in the size of the cells at different parts. They are smaller at the fovea, where they cover nine or ten cones, than at the periphery, where they embrace 20 or more end-organs. But the first effect of a light stimulus—i.e., the chemico-physical change—is probably not different whichever part, central or peripheral, receives the stimulus. A sufficiently large white object appears, for instance, equally bright over the whole field of vision. On the other hand, there is not an equal distribution of rods and cones all over the retina. As a consequence of this the effect of stimulation of the pigment cells is not everywhere the same, so far as the impression goes to which the stimulation gives rise. The excentric form sense is different and much less acute than the central.

Affections of the Light Sense.

This double nature, so to speak, of the retina makes it possible to conceive of visual defects arising from pathological or other changes which involve either one or both of the two elements. That is to say, some affection might impair or destroy the activity of the retinal cells alone, or of the nerve elements alone, or of both at the same time. An affection of the choroid, for instance, might either directly, or through the rich network of blood-vessels from which the pigment cells derive their nutriment, impair the function of these cells without necessarily invading the nerve elements. On the other hand, a process of atrophy of the optic nerve would not involve the pigment cells, and a diffuse retinitis might likely enough include both nerve elements and hexagonal cells in its destructive changes.

Now, what must be the inference as to the manner in which changes in either pigment cells or nerve end-organs might be supposed to cause a departure from the normal in functional activity? With a normal state of the nerve elements the power of discriminating differences in degree of stimulation would remain normal. That is, given the stimulation, the light difference sense would not be affected so far as it depended simply upon the activity of the nerve elements. On the other hand, changes confined to the pigment cells, and to the sources from which their nutriment is drawn, might conceivably lower their response to light vibrations. Consequently the acuteness of the light minimum sense would thus be lowered. If this, again, were to take the form of a greater amplitude of ether vibrations being required to start any chemico-physical response in the substance of the pigment cells, without there being any reduction, when once started, in the relative amount of response, as the strength of the stimulus was increased, there must as a consequence be a light sense defect limited to the light minimum and not involving the light difference sense, which, as we have seen, depends upon the discriminating power of the retinal nerve-end organs. Again, a defect of excitability or conductivity in the latter would conceivably mainly diminish the acuteness of the light difference sense and cause comparatively little lowering of the light minimum.

A priori, therefore, we might have two different affections of the light sense, represented respectively by a bluntness in the light minimum sense without any loss in the sense of light difference in a good light and a diminution of the light difference sense in a good light with little or no increase in the stimulus required to evoke a minimum sensation of light. When we come to consider the manner in which the form sense must be influenced by these conditions, we shall find that they actually do occur, and are characteristic of definite types of disease.

Experiment has shown that physiologically the appreciation of light differences is influenced by both the size of the visual angle and the absolute illumination under which objects are seen. The larger the visual angle the more delicate is the sense of difference in brightness. Up to a certain point, too, the same sense becomes more and more delicate as the intensity of illumination is increased. Roughly speaking, the maximum of acuteness is reached for an intensity of illumination which falls short of causing any discomfort—for what might be called a good light for reading by. Now, it is evident that the criterion that the light sense is normal in any case is that there should be both a normal light minimum and a normal light difference discrimination. One alone is not sufficient. For a visual acuteness test made in the ordinary way there is, for normal eyes, no marked individual difference in the effect produced by altering the intensity of illumination under which a test is made. No doubt, therefore, where we find that the visual acuteness sinks appreciably more rapidly than normally with diminishing intensity of illumination there must be a defect in the light sense. But this symptom of such a defect may have to be looked for. Of two individuals, e.g., whose acuteness is the same, or normal, through perhaps a considerable range, the light sense may nevertheless be abnormal in one. For the acuteness may be found to drop suddenly in the one when a greater reduction in brightness is made. A congenital light sense defect, existing along with full acuteness of vision in ordinary light, is a defect in the light minimum sense alone. A light difference defect is never found along with a completely normal form sense.

In moderate degrees of congenital amblyopia, such as are not uncommon in hypermetropes, the light and colour senses, when tested with objects which do not subtend too small a visual angle, are normal. As we have already seen, the light difference sense depends very greatly, within limits, on the angle under which an object is seen. And the same applies to the colour sense. For minimal visual angles, 1′ to 2′, for instance, even the normal eye is not capable of detecting anything like so small differences of brightness as for such angles, 1° to 2° or more, under which the most frequently applied tests are made. This fact, which has been long known and specially studied by Aubert, is of great importance in explaining the nature of defective sight.

THE COLOUR SENSE.

With regard to the colour sense, it would be impossible within the limits of a single lecture to include much. The subject is a difficult one, moreover, and it will only be necessary to refer to so much as will serve to explain the importance of colour tests for diagnosis. By the colour sense is understood the power of distinguishing qualitatively light of different wave lengths and quantitatively the relative intensities of light of the same vibratory frequency. A distinction must be made between the colour sense and colour perception. Two individuals may have an equally perfect sense for colour; it is easy enough to demonstrate this. On the other hand, it is impossible to assert, however probable it may seem, that their perceptions of colour impressions are identical. Our tests then have only and can only have to do with the colour sense.

There is no absolutely constant connexion found to exist between the physical stimulus—i.e., the vibratory frequency of light rays—and the colour impressions which they produce. The same rays may, according to circumstances, cause quite different colour sensations, and the same colour sensations may result from the action of quite different rays. Some of the conditions that influence the sense of colour are: the intensity of illumination of the coloured light or object, the visual angle under which it is seen, the nature of the background on which it is seen, and the duration of the physical stimulus which produces the impression. A very short subjection to the action of coloured objects gives rise to different colour impressions than those which arise from a more prolonged action. If seen only momentarily, the whole spectrum appears uncoloured and shortened at the red end. A less momentary, but still short, exposure gives rise to only red and blue impressions. The rays which soonest cause their normal impression are the red, the blue take longer, and the green still longer. There is thus exhibited in regard to colour sensations the same phenomenon to which I have already referred—viz., the lapse of a measurable amount of time before the physical stimulus can give rise to its full effect. A positive after-image is again the result of some time also elapsing, on the conclusion of the stimulus, before its effect altogether disappears.

The effect of illumination on colour is familiar in the gradual loss in the impressions of colours in nature as daylight fades into darkness. The effect of the size of the coloured object on the impression produced is easily demonstrated. It is different for different colours. Whereas a small green object completely loses its colour before disappearing, it is not so easy to observe the same effect in the case of a small red object.

Colour impressions got from the spectrum are more vivid—i.e., their hue is more saturated—than those got from coloured objects. But even the spectral colours are not the most saturated which it is possible to see. More vivid impressions still are got when the images of spectral colours fall on parts of the retina which have immediately before been stimulated by rays complementary to those in the new image. Fatigue therefore for one set of rays causes a heightened impression for rays which are complementary to them. This fatigue for colours is in some way connected with the physico-chemical changes which take place in the retinal pigment cells. Possibly it is only partly due to the using up of the chemical material and related more intimately, as in muscular fatigue, to the accumulation of waste products. If, for instance, we look for a few seconds at a large sheet of brightly and uniformly coloured paper, on a part of which is laid a small piece of dead black paper, it is found that on withdrawing the black paper the part of the coloured surface, which then comes to occupy the place of the image, is projected as a much more vivid colour than the rest of the surface by which the surrounding retina has been continuously stimulated. And the same influence of fatigue, though not so uncomplicated, is seen in changing the position of the retinal images of external objects by looking at them with the head in some other position. The existence of this kind of fatigue should be remembered, as it may become more marked in disease.

CENTRAL VISUAL DEFECTS FROM PATHOLOGICAL CHANGES.

We are now in a position to take up the consideration of how defects of vision which occur from pathological changes must be explained. We are not concerned, of course, with defects due to changes in the dioptric media or with such as cause retinal metamorphopsia. When the images formed on the retina are accurate, the distinguishing power of the eye is physiologically lowered—i.e., the strength of the stimulus is diminished—either by reducing the absolute

brightness or by diminishing the contrast between it and its background of an object seen under a constant visual angle. Consequently, pathological changes which reduce the strength of the impressions which objective stimuli make on the nerve mechanism of the eye must explain also the lowered visual acuteness which accompanies them. Diminished excitability or diminished conductivity must have this effect.

The detection more especially of an interference with nerve conductivity is an important factor in diagnosis. It is only with tests capable of indicating with delicacy the limits of functional activity that it is possible to detect the early stages of many affections.

We start, then, with the conception that anything which reduces the stimulability of the single cone (and we are for the present only considering central or foveal vision) will also reduce the acuteness of vision. We find, in fact, that a small object, white on a black or black on a white background, say a disc of 1 mm. diameter at a distance of 10 or 11 feet, an object which therefore subtends an angle of little more than 1′ (the angle adopted for Snellen's types), if seen at all disappears sooner altogether from view for a diseased, as compared with a normal eye, when its brightness is gradually reduced. Yet there may be no apparent difference in the brightness of the more extensive background in the two cases. It is only therefore when the visual angle is sufficiently small that the difference becomes apparent. If an amblyopia is not very great, the visual acuteness not lower than say 1/6 or 1/7 of the normal standard, even a white object 10 mm. in diameter at a distance of a foot does not appear to differ appreciably in brightness from the impression which it causes on the normal eye. The conditions are in this respect similar to what obtains for normal excentric vision. An object of this size is seen equally bright over the whole field, although the excentric acuteness of vision is much less than the central, and increasingly less the more excentric the image comes to lie. In a case of toxic amblyopia, too, a white object of the same size and at the same distance may not appear any less bright when its image falls within the central scotoma than it does elsewhere over the field of vision, while a much smaller white object, though visible excentrically to the scotoma, may not be seen at all within the area of the scotoma.

It must be admitted that this difference in apparent brightness, according as the retinal image is a very small one or one of sufficient extent, is not quite easy to explain. It is difficult to see why, on the assumption of diminished excitability or stimulability of each individual retinal element, the larger surface should produce a different effect from the smaller. The difference is not confined to quite minimal objects when compared with large ones. It is seen also for objects subtending angles of 5′–6′ or more, and cannot therefore be ascribable wholly to the effects of aberration. It seems reasonable to suppose that the difference in the impressions produced is due to a summation of the stimuli. When a large area of the retina is embraced the limit of stimulation capable of evoking an impression may be different from that for the stimulation of each individual cone. This seems to be consistent with the observed facts in regard to excentric vision. It has also been conjectured that pathological changes causing defective visual acuteness may not lower the excitability of the end organs, but cause a loss in the isolation of the conducting fibres with which each is associated, and consequently an irradiation of the stimulus. If this were really the case the summation of irradiations over a comparatively large image would account for the difference between its apparent brightness and that of an equally bright small image. It seems impossible to assert positively that, to some extent at least, this loss of isolation may not take place. Indeed, it is not unlikely that it does, but the matter is too speculative to discuss at length in this lecture. One difficulty, however, in accepting the loss of isolation explanation is that were it the main cause of visual defects, one would expect to find that a very small object, if sufficiently bright, would appear larger in cases of optic nerve disease than to the normal-sighted eye, and this, if it ever is the case, is certainly not generally so.

Determination of the Light Sense.

But whatever be the true explanation, the practical conclusion to which one has to come is that a determination of the visual acuteness in acquired defects of vision is tantamount to a determination of whether the light difference sense for a minimal visual angle is normal or not. These two hang together if the examination is made in ordinary daylight. This, then, is the justification for adopting the clinical methods of determining the condition of the light sense in preference to the quantitatively more accurate scientific methods. By Bjerrum's method the examination is made with the same ease as in the ordinary test for visual acuteness. The other methods take up more time.

For ordinary clinical purposes all that is required is to get a trustworthy indication of a diminution of the light sense—whether of the light minimum or light difference. A definite measure of the particular defect, though interesting, is not necessary for diagnostic purposes. Therefore in taking the light minimum sense we note the manner in which visual acuteness as tested with Snellen's types falls off with diminished illumination, and in testing the light difference sense the manner in which acuteness sinks for test types graduated like Snellen's, but in which the contrast is not black on white but grey on grey. Tests made in these ways show that in some forms of defective vision from disease the acuteness sinks very much more as the illumination is lowered than it does in other cases where the defect in vision is nevertheless the same in degree when tested in ordinary daylight. They show also that in other types of disease the acuteness instead of diminishing with abnormal rapidity on reduction of the illumination is retained, or it may be only very slightly lessened, so that the degree of the defect is relatively less with a feeble illumination than for an examination made in full daylight as compared with normal conditions of sight. There may further be shown by these tests that a marked difference between two otherwise equal degrees of amblyopia may exist in the visibility of Bjerrum's grey on grey types. One case may show a very marked reduction in the power of distinguishing the types, and therefore a loss of acuteness for light differences, while another may exhibit no abnormality in this respect.

A relatively bad visual acuteness when the illumination is lowered characterises the state of the light sense in all choroido-retinal affections. In some cases this symptom is more marked than in others, when it is not uncommon to find that there may be a spontaneous complaint of night blindness. The condition is, in fact, a light minimum sense defect; more light is required to elicit the functional activity of the retina than is required normally. Pathologically, it is a retinal pigment affection. A relatively great defect in the light difference sense, shown by abnormally diminished acuteness for the grey on grey types, is characteristic on the other hand of all the conditions where the principal pathological changes are located in the optic nerve.

We have, therefore, when testing the central vision alone, a ready means in the use of Bjerrum's grey on grey types of detecting not only cases in which there is a light difference defect for objects subtending a large, but also for such as subtend a small, visual angle. And in many cases a defect only exists, in point of fact, for vision under a small angle. The same is the case with regard to the colour sense. It may be perfectly normal, and there may consequently be no difficulty in matching or naming colours when the coloured surface presented to view is sufficiently extensive, and yet be quite evidently abnormal when very small coloured objects are used as a test.

This is the reason why some people who cannot recognise at all, or at least with uncertainty, the colour signals used on railways or at sea are yet able to pass the Holmgren and similar tests without difficulty. It is not the defect of the test as a test for colour blindness, nor an indication of the incorrectness of any particular theory of colour vision, that has to be blamed in these cases. It is simply that such individuals are really only defective in their colour sense for minimal visual angles just as others are only defective in their light difference sense for the same minimal angles. The practical indication which this affords is that those who have to recognise signals must be tested for small visual angles—tested, in fact, under conditions which are comparable with those under which they are actually placed in regard to signal lights.

EXCENTRIC VISUAL ACUTENESS.

It is then, because of the perfection of the central form sense, that one does not require, for purposes of diagnosis, to have recourse to any other test than the recognition of Snellen's types, either black on white or grey on grey when

the test is made in ordinary daylight, or to test the acuteness for these types under a feebler illumination. In this way we include the necessary tests under a minimal visual angle, and thus ascertain the state of functional activity of individual retinal elements. When, however, we come to tests for excentric visual acuteness, we have to adopt other measures.

The differences between central and excentric vision are differences in degree only. Consequently, the inferences which may be drawn as to the causes of defects in excentric vision are similar to those which have already been discussed. We are not in the habit of paying any close attention to the details of excentric impressions. Therefore the same tests as those for visual acuteness of foveal images are not practically applicable.

Besides being of a more rudimentary nature all over, the sense of form diminishes in acuteness with the degree of excentricity of the retinal image. This diminution takes place gradually. There are no noticeably sudden differences. Anatomically, the most apparent difference between the fovea and other parts of the retina is the gradual diminution in the number of cones which are met with in the latter for more and more excentric portions, the place of the cones being taken up by rods instead. This has given rise to the assumption that only the cones and not the rods have to do with vision. It is difficult, however, to reconcile this assumption with certain known physiological facts. A very small object, if sufficiently bright, is seen continuously as its image is caused to fall more and more excentrically on the retina. If its image only produced a visual impression when it fell on a cone, or when some part of its diffusion circle caused the stimulation of a cone, it would surely disappear and reappear, or at least undergo appreciable changes in brightness, as it passed from the centre to the periphery. But this is not found to take place. Moreover, the sense of movement of an object in the field of vision is too acute to be accounted for by cone images alone. For these and other reasons it is difficult to avoid the conclusion that the stimulation of the rods also gives rise to visual impressions, whatever other function they may subserve. There must be other reasons why the excentric form sense is so much less acute than the central. There is good reason for believing, e.g., that the peripheral cones have not each, like those of the fovea, an isolated connexion with their nerve continuations, but share this connexion with the rods which surround them. It is also very probable that each element *per se* is not so excitable as a foveal cone.

Excellent and necessary as the ordinary perimetric test with a white or coloured object, one centimetre or half inch square, is in many cases, it has to be kept in mind that it is a very rough one when compared with the ordinary test for central visual acuteness. It comes, indeed, very far from being a test of the functional activity of individual end-organs such as we approximate to, at all events, in the central vision tests. The image of an object only half inch square at a distance of one foot from the eye, the distance of the perimeter arc, must cover more than 20,000 rod and cone ends. To make a practicable test under sufficiently small visual angles the object must be smaller and be placed at a greater distance from the eye. The distance usually chosen, that at which the screen in Bjerrum's screen test is placed, is 2 metres.

It is obvious that the projection of any part of the fundus on a surface 2 metres distant must be something like seven times greater in diameter than it is on the arc of the perimeter. Thus the blind spot projected to this distance covers an area of about 7 inches in diameter instead of only about 1 inch for the perimeter.

Now, it is found that the normal extent of the field of vision varies with the size of the test object used until at any rate that object is one which is seen under a visual angle of about 1/2°. The smaller the visual angle the smaller also is the field in all directions. Bjerrum found that in general the most practically useful size of object with which to make a test at 2 metres is a disc of 3 mm. in diameter. This corresponds to a visual angle of 5′. It is sometimes, however, desirable to make use of still smaller objects. This is better than removing the screen further from the eye, though both methods may occasionally be resorted to as, e.g., in exploring a central scotoma.

For a 3 mm. disc at 2 metres, what according to Bjerrum's notation is usually called a 3/2000 test, the extent of the normal field is roughly 35° outwards, 28° inwards, 30° downwards, and 25° upwards. In this respect, however, individual differences may be found, just as is the case with central visual acuteness. The differences met with may also depend to some extent on individual power of attention. Such a test cannot, therefore, lay claim to anything like mathematical accuracy. This, which applies also more or less to all subjective tests, seems often to be lost sight of. It is therefore important to avoid attaching undue weight to slight apparent concentric limitations. Owing to diffusion of the image optical defects cause a narrowing of the boundaries, though only to a slight extent. The intensity of illumination of the test object and the size of the pupil have also an influence in this respect. On the other hand, sectoral or other peripheral restrictions, or scotomata, if met with under any conditions of refraction or illumination, are evidences of pathological changes in functional activity. The detection of the boundaries for small white objects is, as a rule, given average attention on the part of the patient, a very easy matter. It is less difficult to obtain a correct estimation of these boundaries, when all that is required is to note when the test object ceases to be visible at all, than it is to fix the boundaries for colour, as it is not easy, even for people with some power of observation, to say when an excentric colour impression changes or disappears altogether.

By determining, then, the limits of the field of vision for small objects of gradually increasing size we obtain what is tantamount to a measure of the visual acuteness over different parts of the retina. For instance, one physiological condition, whose existence cannot otherwise be demonstrated, is the presence of a narrow zone of the retina surrounding the intra-ocular end of the optic nerve for which the vision is considerably less acute than it is immediately beyond, or indeed anywhere excentrically, except near the extreme periphery. This zone, whose projection measures fully an inch in breadth with the 3/2000 test, therefore correspondingly increases the area of the scotoma marking the blind spot as compared with the size for which that physiological scotoma is absolute.

One thing that is most noticeable and instructive where the normal conditions are departed from is that the shape of the field of vision as marked out by, e.g., a 3/2000 test, is by no means always, or even generally, a sort of contracted miniature of that which may be found by the ordinary perimetric examination. It may, in fact, have a completely different form. The reason of this is obvious. The one is a test to detect the loss in acuteness of vision at any part of the retina, the other is a test for the detection of the area of actual blindness.

Value of the Screen Test in Various Conditions.

For the detection of a relative scotoma, therefore, the small object test may be quite essential. Even an absolute scotoma, if small, may escape detection if the perimeter test alone is relied upon. To get the image of the perimeter test object to cover a small absolute scotoma is not easy even when it is carefully looked for, so that the patient is conscious of the complete disappearance of the white object. The scotoma has to be projected to a greater distance before it can be mapped out with certainty.

But with the small visual angle tests one can do more than merely map out the area of a scotoma. It is also possible in many cases, if time be given for the examination, to estimate the degree of the defect in different parts of a scotoma which is wholly or partially only relative. If, after beginning with a very small test object, and noting the size of the area over which it is invisible, successively larger and larger test objects are used, the shape of the scotoma may be found to alter, or the area for which a continuously defective acuteness was at first found may split up into two or more portions for which the acuteness is less than that of the intervening portions in which the larger test objects are recognised.

There is another class of cases, which are no doubt less frequently met with, in which the same test may give valuable information—viz., cases in which there is pressure on the optic nerve, the tract or the chiasma. Here the test may prove a delicate one from the point of view of prognosis. It comes, in fact, to be a gauge of the degree to which conductivity in the nerve fibres is affected by the pressure. In some cases, if closely followed, a variation in the excentric acuteness from time to time will suggest an intermittency

of pressure such as might be produced by varying degrees of vascular engorgement in a tumour causing the pressure. There is much work to be done yet in this connexion; work which involves time and patience. Quite recently some interesting points in connexion with acromegaly have been investigated by Traquair with the screen test. His results, which afford, with a delicacy not otherwise obtainable, an indication of constant or varying pressure on the chiasma, are of importance in connexion with the question of operative interference in such cases.

In cases also of choroiditis, of progressive myopia of a severe type, of retinitis pigmentosa, of neuritis, of optic atrophy, and of glaucoma, the screen test as a means of detecting localised diminutions of excentric visual acuteness gives information of diagnostic and prognostic value which would necessarily often escape observation by the ordinary perimeter test alone. In choroiditis the extent of a central defect or of a circummacular, continuous or interrupted, ring-shaped scotoma, can thus be demonstrated. In progressive myopia the earliest symptoms of macular and circumpapillary degeneration are revealed. In retinitis pigmentosa the 3/2000 test always brings to light the existence of marked concentric limitation—i.e., a drop in the acuteness of excentric vision long before an absolute limitation can be made out by a perimetric test with its test object subtending a much larger visual angle. In neuritis the enlargement of the boundaries of the blind spot and, as also in atrophy, the many different ways in which the excentric vision is reduced and lost can be mapped out.

In glaucoma we possess in the 3/2000 test a means of diagnosis before even any other appreciable signs or symptoms of the disease exist. In the glaucoma field, which may assume an almost infinite variety of forms, there can nearly always be recognised one appearance which is peculiar to glaucoma, and which was first discovered by Bjerrum as the result of the application of his screen test. This characteristic symptom consists in the area of relative loss of acuteness—i.e., the area over which the test object is invisible—being always traceable up to the blind spot, while at the same time some other portion of the blind spot is found forming part of the boundary of the field for which the test object is still visible. This peculiarity can only exceptionally be found by the perimeter test—only, in fact, when the vision is altogether lost in the corresponding area. The screen test is also useful for the detection and elucidation of an incomplete hemianopia as well as for discriminating between different forms of a central amblyopia.

The Condition of the Excentric Colour Sense.

The perimeter and screen tests with white objects, by which concentric or otherwise circumscribed, blind, or defective areas can be detected in the field of vision, and which thus afford evidence of pathological changes in the functional activity of the excentric portions of the retina, are the most valuable tests which can be applied. It is also, no doubt, of interest to test the condition of the excentric colour sense. But from a diagnostic and prognostic point of view the information thus got is of less value. Abnormal restrictions of the colour field, it is true, are evidences of diminished visual acuteness. They are early symptoms of the lowering of conductivity. Colour tests are also useful and of easy application for detecting the presence of a relative central scotoma in cases, for instance, of toxic amblyopia. But there is little use in any affection of mapping out the boundaries of the field for a number of differently coloured objects—red, green, blue, and yellow—as is so often done. Even in the case of altogether normal eyes such a test leads to the discovery of not inconsiderable individual differences. I have already remarked, too, that the exact limits of recognition excentrically of the colour apart from the coloured object is not quite an easy matter. Very great care is, therefore, required to satisfy oneself of the accuracy of statements made by patients. Consequently, we must exercise care in drawing inferences from any apparent differences in the results of the same tests made at different times in the course of any affection. When sufficient care is taken, and there is a sufficiently marked difference in the response to the test after an interval of time, no doubt the indication thus given of a change in functional activity may be relied upon.

Apart from this practical objection, however, I believe that, as generally applied, the tests for excentric colour vision are unnecessarily complicated, owing to their being made on a wrong principle. The physiological fact is lost sight of that the limits of the field of vision for any particular colour are always the same as those for the colour which is complementary to it. If it were not so, and it is not very difficult to prove that it is, a white object would not be seen uncoloured over the whole of the field of vision. Consequently, when one sees stated or charted that the green field in any case is narrower than the red or *vice versâ*, one knows that the colours used are not complementary, or at all events, if by chance they should be complementary, have not in addition the same neutral or white value. Only one colour should therefore, as a rule, be used for clinical purposes, preferably a red or green. The exact colour chosen, too, should be one which retains its hue in every part of the field for which it is visible. Another colour, blue or yellow, whose particular hue, as seen excentrically, is in the same way invariable, may occasionally be required when the red or green object, either as the result of disease or of congenital colour confusion (so-called colour blindness) is altogether unrecognisable excentrically.

CONCLUSIONS.

What I have aimed at in this lecture is to draw inferences to explain defective vision from disease by comparison with certain known facts in the physiology of vision. Further, having done so, I have attempted to justify the selection which I advocate of the different methods for the subjective examination of central and excentric vision. I have also pointed out some of the conclusions to which the results which may be got by such examinations lead.

We have seen that, physiologically, when the intensity of a light stimulus, acting only on a few end organs of the retina, is diminished in any way—that is, when either the brightness of the test object or the contrast between it and its background is diminished—then the visual acuteness, the power of recognising detail, is lowered. And for diminished intensity of stimulus in the case of the normal eye we have assumed diminished excitability, conductivity, or receptivity in that of the diseased eye. *A priori* the result must be the same in both cases.

That the assumption is justifiable is shown by the fact that in every case of acquired visual defect, with obvious exceptions, the light sense for small visual angles is diminished. As this is not necessarily the case for larger visual angles, it follows that a summation of feebler individual impressions must have the effect of causing a stronger total impression. We have found that both the light and colour senses are greatly dependent upon the size of the angle under which any object is seen. The eye is unable to detect anything like as small differences in the intensities of contiguous retinal stimuli under a small, as it does under a greater, visual angle. And this circumstance, when taken along with the physiological imperfection of the retinal images of external points, is the reason why visual acuteness is greater in what we call a good light than it is in a sufficiently bad light. Thus is explained the drop in acuteness which takes place, physiologically, in the dark—a drop which is, however, greatly modified by retinal adaptation. Thus also is explained the drop which takes place, pathologically, when the excitability or conductivity of the nervous mechanism is lowered. And it is obvious that, given normal optical conditions of the eye, a diminution in visual acuteness must depend upon some change in the retina, or its direct connexions.

I have left out of consideration those visual defects which come from optical errors alone. The explanation of these is simpler. The diffusion circles of the images of objective points are of quite another nature than those which are due to aberration. It is interesting, however, to note in connexion with the subject of the lecture that, as a rule, the visual acuteness of an ametrope is relatively better when compared with that of an emmetrope when the light is insufficient to permit of full vision in the case of the latter. This is due, of course, to the absence, generally speaking, in the ametrope, *quâ* his ametropia, of any light sense defect

Finally, as regards the methods of examination, we have seen that for foveal vision it is easier and, for clinical purposes, sufficient to test the acuteness for Snellen's types under ordinary and reduced illumination and contrast, than to determine the limits of invisibility with the photometer and Masson's disc. We have seen further that similar tests

are not suitable for the examination of excentric vision, and that an estimate of visual acuteness at other parts of the retina than the fovea must be made with objects which subtend a very small visual angle.

SYMMETRICAL NECROSIS OF THE CORTEX OF THE KIDNEYS

ASSOCIATED WITH SUPPRESSION OF URINE IN WOMEN SHORTLY AFTER DELIVERY.

BY H. D. ROLLESTON, M.D. CANTAB., F.R.C.P. LOND.,
SENIOR PHYSICIAN, ST. GEORGE'S HOSPITAL; PHYSICIAN, VICTORIA HOSPITAL FOR CHILDREN.

SYMMETRICAL necrosis of the cortex of the kidneys is rare and is almost only seen in women directly after childbirth, in whom ten cases have been reported (Bradford and Lawrence,[1] Griffith and Herringham,[2] Lloyd,[10] Klotz,[9] Jardine and Teacher[6] (2 cases), Torrens,[12] and Jardine and Kennedy[7] (3 cases)). The one recorded below brings the total up to 11. (See Table I.)

Griffith and Herringham's patient vomited frequently and had headache during the earlier days of the illness, but these may have been due to chronic nephritis; in my case drowsiness and vomiting occurred in the early stages; and convulsions are recorded in six cases. But in 2 out of these 6 cases the convulsions occurred only before the uterus was emptied (Jardine and Teacher, Case 2, Jardine and Kennedy, Case 3), and therefore cannot be so distinctly correlated with the anuria as in the other 4 cases. In 2 cases (Lloyd, Klotz) convulsions occurred after delivery; in 1 case (Jardine and Kennedy, Case 2) just before death, and in 1 case (Jardine and Teacher, Case 1) both before and after delivery. It is interesting to inquire if the occurrence of convulsions can be correlated with the presence of old-standing renal disease, and the absence of convulsions with a previously healthy state of the kidneys. (Table II.) Of the 5 cases in which convulsions did not occur the kidneys were previously healthy in 3, showed endarteritis without renal fibrosis in 1 (Bradford and Lawrence), and chronic nephritis in 1 (Griffith and Herringham). Of the 6 causes in which convulsions occurred the kidneys were previously healthy in 2; in 1 case—a woman of 22, in whom 12 fits occurred before delivery—there was very slight endarteritis only, and

TABLE I.—*Giving Particulars of the 11 Reported Cases.*

Authors.	Age of patient.	Condition of child.	Duration of anuria.	Uræmic symptoms.	Condition of kidneys, &c.
Thrombosis of Interlobular Arteries.					
Bradford and Lawrence.	36 7-gravida.	Dead child.	7 days.	Absent.	Endarteritis of interlobular arteries. Veins healthy. No fibrosis of kidneys.
Griffith and Herringham.	35 multigravida.	,,	6 days.	Almost absent.	Chronic nephritis. Retino-papillitis.
Lloyd.	39 multigravida.	Stillborn.	11 oz. in 11 days.	Convulsions after delivery.	Chronic interstitial nephritis.
Jardine and Teacher, Case 2.	22	,,	About 9 oz. in last 7 days.	Convulsions before and coma after delivery.	Very slight endarteritis only.
Klotz.	25 1-gravida.	Cæsarean section.	Not complete.	Two convulsions 7 days after Cæsarean section; occasional dyspnœa.	Some old change.
Jardine and Kennedy, Case 3.	23 2-gravida.	4-months pregnancy.	1½ days.	Several fits before uterus was emptied. Vomiting; semi-coma; and hiccough before death.	No old change. Scanty thrombosis in arterioles and capillaries.
Thrombosis of both Interlobular Arteries and Veins.					
Jardine and Kennedy, Case 1.	34 9-gravida.	Dead fœtus, 7-month.	4½ days.	Occasional dyspnœa; no coma; no fits.	No old change.
Jardine and Kennedy, Case 2.	36 2-gravida.	Live twins at eighth month.	2½ days.	Persistent vomiting; fit before death only; semi-coma 24 hours.	,,
Jardine and Teacher, Case 1.	36 7-gravida.	Dead fœtus.	5½ days.	Fits before and after delivery.	Slight subacute interstitial nephritis and arterio-sclerosis.
Rolleston.	48 14-gravida.	Macerated fœtus, 14 days overdue.	8 days.	Dyspnœa; drowsiness and vomiting in early stages; twitched before death.	No old change. Thrombosis of ovarian and renal veins.
Thrombosis of Interlobular Veins.					
Torrens.	29 multigravida.	Abortion at fourth month.	8 days.	Absent.	No old change. Thrombosis of renal veins.

The ages of these 11 patients varied between 22 and 48 years. Nine were multigravidæ, one was a primipara, and in one case there was not any statement. In one case only was there a live birth (Jardine and Kennedy, Case 2) and in that instance there were live twins. The exception to the statement that symmetrical necrosis of the renal cortex is a puerperal manifestation is that in very rare instances embolic infarction may be so extensive as to produce this anatomical lesion. Juhel-Rénoy[8] described symmetrical necrosis of the renal cortex in a girl, aged 16 years, after scarlet fever, due to microscopic emboli in the interlobular arteries.

The *clinical features* are remarkable in resembling in the main those of calculous obstruction of both ureters rather than those usually regarded as characteristic of non-obstructive anuria. Although uræmic manifestations were absent in some of the reported cases and when present were usually comparatively slight, analysis of the 11 collected cases does not justify the statement sometimes made that uræmia is constantly and entirely absent. Dyspnœa occurred in 3 cases (in Jardine and Kennedy's first case, in Klotz's case, and in my case); Jardine and Kennedy's second patient vomited and for 24 hours before death was semicomatose; their third patient vomited and had hiccough;

TABLE II.—*The Pre-existing Renal Condition in Relation to the Occurrence of Convulsions.*

Cases without Convulsions.

Authors.	Condition of kidneys.
Bradford and Lawrence	Endarteritis.
Griffith and Herringham	Chronic nephritis.
Jardine and Kennedy (Case 1)	No old change.
Torrens	No old change.
Rolleston	No old change.

Cases with Convulsions.

Authors.	When convulsions occurred.	Condition of kidneys.
Lloyd.	After delivery.	Chronic interstitial nephritis.
Jardine and Teacher.	Case 1.—Eight fits before and one fit after delivery.	Slight subacute interstitial nephritis.
	Case 2.—Woman, aged 22; 12 fits before delivery.	Very slight endarteritis.
Klotz.	Two fits after Cæsarean section.	Some old change.
Jardine and Kennedy.	Case 2.—Convulsions before death only.	No old change.
	Case 3.—Several fits before the uterus was emptied.	,, ,,

in the remaining 3 cases there was old change. There is, therefore, some, but not overwhelming, evidence in favour of the view that pre-existing renal change favours the occurrence of convulsions.

Although anuria was not absolutely complete in Lloyd's case (11 oz. in 11 days) and in Jardine and Teacher's second case (9 oz. in 7 days), it is a striking feature in nearly all these cases. In Bradford and Lawrence's case anuria lasted 7 days, in Griffith and Herringham's 6 (only 10 oz. being passed in the last 10 days), in Jardine and Teacher's first case 5½, in Jardine and Kennedy's first case 4½, second case 2½, third case 1½, in Torrens's case 8, and in my case 8 days. Klotz's case is peculiar in the comparatively large amount of urine passed; in the last 15 days of life the patient passed more than 76 oz. of urine and voided as much as 16 oz. two days before death.

The *morbid lesions* are remarkable in showing symmetrical necrosis of the renal cortex with thrombosis of the renal vessels supplying the cortex, usually of the interlobular arteries in the middle zone of the cortex. In some of the cases (Jardine and Teacher (Case 1), Klotz, Jardine and Kennedy (Cases 1 and 2), and my case) there was a narrow rim of unaltered cortex immediately under the capsule. Its escape appears to depend on the anastomosis between the arteries in the capsule of the kidney and those supplying the perirenal fat, and resembles the condition often seen in ordinary embolic infarction of the kidney.

The *vascular changes* are not absolutely identical in all the cases. Bradford and Lawrence's case showed old endarteritis with recent thrombosis; thrombosis of the interlobular arteries was reported in four other cases (Griffith and Herringham, Lloyd, Jardine and Teacher (Case 2), and Klotz); thrombosis of both the interlobular arteries and veins in four cases (Jardine and Kennedy (Cases 1 and 2), Jardine and Teacher (Case 1), my case); scanty thrombosis of the arterioles and capillaries in Jardine and Kennedy's third case; and thrombosis of the veins alone in Torrens's case. Torrens's case and my case differ from the other nine cases in the presence of thrombosis in the main renal and ovarian veins in addition. In these two cases three possibilities arise: (1) that the thrombosis in the intrarenal veins spread to, or caused the thrombosis in, the extrarenal vessels; (2) that the thrombosis in the two situations was simultaneous and independent; or (3) that the thrombosis spread from the large veins into the interlobular vessels. In the first instance the last view seemed probable in Torrens's case, but the absence of thrombosis of the extrarenal veins in the other published cases, which are in other respects similar, naturally causes some hesitation in adopting this explanation. In my case the left renal vein contained some loose granular clot, but the right renal vein was free from clot, although both the ovarian veins were thrombosed; extension of thrombosis from the extrarenal to the intrarenal vessels therefore appears less probable than in Torrens's case.

Cause of the thrombosis.—In the first recorded case (Bradford and Lawrence) endarteritis of the renal arteries was regarded as the cause of the thrombosis, but this appears to be almost the only instance in which this sequence is at all probable. In Jardine and Teacher's second case, in which there was slight endarteritis, the face and arms presented a lividity resembling that of the stage of local asphyxia in Raynaud's disease. This suggested the hypothesis that spasm of the renal arteries determined the thrombosis. But as the Raynaud phenomenon was not noted in the other ten cases this explanation cannot be adopted. Klotz, who described the thrombi as finely granular and due to hæmolysis of red blood corpuscles, believes that the thrombosis occurred simultaneously in all the renal vessels, as a result of certain metabolic disturbances of secretion in pregnancy. Kennedy, like Parkes Weber,[13] considers that the thrombosis is secondary to the necrosis, which may be assumed to be due to toxæmia. In favour of his view that the necrosis is due to the poison of eclampsia Kennedy points out that focal necroses were present in the liver in two out of his three cases. But Klotz, who compares the thrombi in the renal arteries to those in an eclamptic liver, definitely states that there was no focal necrosis in the liver in his case. As Dr. R. S. Trevor points out in his report on my case, there is an obvious objection to the view that the thrombosis is secondary to the necrotic changes in the cortex—namely, that a similar thrombosis does not occur in other forms of toxic nephritis however severe. I am not aware of any evidence that the blood of healthy parturient women is prone to coagulate. The phlebo-thrombosis seen in this state is due to infection; and there does not appear from the 11 recorded cases of symmetrical necrosis of the renal cortex, especially Klotz's, in which this point was considered, to be convincing evidence of a primary local infection of the kidney. Possibly the thrombosis is in the first instance due to the same toxæmia which causes degeneration of the renal cells, and that the thrombosis then causes complete necrosis of the cortex.

Remarks on the symptoms.—It is not at first sight obvious why the symptoms differ so markedly from those of anuria due to extremely acute nephritis. Herringham [4] has recently pointed out that "we do not in our ordinary views allow enough for the effect upon the general system which is produced by the diseased cells of the kidney," and he suspects that products are absorbed from them which are very hurtful. A possible explanation of the difference between the symptoms in the two conditions is that when the renal vessels become thrombosed the circulation is so interfered with that little or no absorption of toxic products from the necrotic renal cortex can occur. In connexion with this suggestion reference may again be made to Juhel-Rénoy's case of multiple microscopic embolism of the interlobular arteries with necrosis of the cortex in which there was anuria for 6 days, but with such freedom from uræmic symptoms that hysterical anuria was at first suspected; subsequently œdema of the feet appeared. In some of the 11 collected cases the uræmic symptoms were more obvious in the early days of the suppression of urine, and it might be urged that this was before thrombosis had supervened and brought the renal circulation to a standstill, and so prevented absorption of toxins from the damaged kidneys.

Occlusion of the renal arteries supplying the glomeruli and the convoluted tubes of the kidney might thus be thought to put the patient in a condition analogous to that of double nephrectomy. There are few published accounts of cases in which a single or solitary kidney has been removed. Polk [11] recorded extirpation of a misplaced kidney in which the woman lived 11 days after removal of her only kidney, the clinical features being much the same as in calculous anuria, and I have had verbal information of a few similar cases. In 1898 Bradford and Lawrence [1] stated that there is no great difference in the phenomena between complete extirpation of both normal kidneys on the one hand and double ligature of the ureters on the other hand in animals. And more recently Jackson and Saiki [5] found that when all the conditions are constant animals after double nephrectomy survive operations longer than animals with ligature of both ureters.

Œdema is not produced by symmetrical necrosis of the renal cortex; when present it is due to pre-existing nephritis.

Summary.—Symmetrical necrosis of the renal cortex is almost invariably related to recent delivery, and the child is almost always stillborn. The symptoms resemble those of obstructive anuria, but uræmic manifestations are not entirely absent. The kidneys may have been previously either healthy or diseased. The necrosis of the cortex is a characteristic lesion, and is intimately connected with thrombosis of the interlobular renal vessels, but the exact relation between these two events is open to discussion.

The following case was under my observation:—

Thombosis of the ovarian and renal veins; symmetrical necrosis of the renal cortex; anuria.—A woman aged 48, who had had 13 children, 9 of whom are living, and 2 miscarriages, was delivered on March 6th, 1913, of a macerated fœtus which was 2 weeks overdue. The labour, which lasted 12 hours, did not require instrumental assistance. On March 8th she became rather drowsy, and on the following day had abdominal pain and ceased to pass urine. She vomited every day from the date of her confinement until March 12th, when she was admitted under my care at St. George's Hospital. She was then anæmic, rather drowsy, but perfectly intelligent and alive to her surroundings. The heart, lungs, and abdomen appeared normal. The pulse, 100, had a systolic blood pressure of 115 mm. Hg. The temperature was subnormal. By catheter 1 c.c. of pale neutral fluid, containing blood, pus, and albumin, was drawn off from the bladder; on March 13th no urine could be obtained by catheterisation, but on the 14th and 15th a few c.c. with the same characters as before were drawn off. On the 13th a skiagram of the kidneys did not show any evidence of a calculus; before this was done Dr. J. A. Torrens, the medical registrar, had suggested that the condition was one of thrombosis of the renal veins, basing this on the resemblance to a case previously published by him.[12] On the 14th there was noticeable dyspnœa, and the blood pressure was

120 mm. Hg. On the 16th the blood pressure was 120 mm. Hg, dyspnœa was again very well marked, there was severe abdominal pain—mainly on the right side—and no urine was passed. The temperature ran up to 102° F. and the pulse to 136. On the 17th the temperature had fallen to 97°, and there was slight twitching of the face. At 2.30 P.M. the blood pressure had fallen to 60 mm. Hg; at 3.30 P.M. the face twitched slightly and the patient died quite suddenly. She was mentally alert to the end. There was no vomiting while in the hospital, and no œdema of the subcutaneous tissues.

The *necropsy* was performed by Mr. J. R. H. Turton. The right utero-ovarian plexus of veins was filled with dark blood-clot and produced a prominent swelling at the commencement of the right ovarian vein in the upper part of the broad ligament. There was not any extension of the clot into the iliac veins. The right ovarian vein was completely distended with clot and formed a conspicuous object on the posterior wall of the abdomen. The clot, about an inch in length and a quarter of an inch in diameter, projected into the inferior vena cava, lying free in the lumen of the vessel but not filling its cavity. The right ovarian vein opened into the inferior vena cava about one and a half inches below the renal vein which was free from clot. The left ovarian vein contained some granular clot adherent to its wall opposite the brim of the pelvis. There was a small pale clot, apparently detached from this, at the opening of the left ovarian vein into the left renal vein and lying free in the vein. The left renal vein in the hilum of the kidney contained a loose granular clot, extending from the hilum to within three-quarters of an inch of the entrance of the left ovarian vein. The vein wall was healthy. The kidneys, 8 oz. each, showed symmetrical necrosis of the cortex, which was dull yellow in colour; there was a thin rim of healthy cortex under the capsules. The remaining kidney substance appeared healthy, and the capsules stripped off normally. The arteries were healthy. Cultures from the spleen and the blood clot in the ovarian vein both showed *Streptococcus pyogenes*, pure in the blood clot, but with *Bacillus coli* in the spleen. The uterus was normally involuted.

I am indebted to Dr. Trevor for the following account of the microscopical examination:—

On microscopical examination the necrosis affects the cortex irregularly in both kidneys. For the most part the whole of the cortex from the medulla to the capsule is affected—a narrow zone only immediately under the capsule being free. The width of this zone even is variable and in one or two places, especially in the left kidney, the necrosis extends quite to the surface, which is slightly depressed. On the medullary side the necrosis reaches downwards in patches to the boundary zone, leaving unaffected areas of cortex in between. The latter, however, are not healthy, the tubal epithelium being degenerated, the cells vacuolated and broken up, whilst many of the tubules contain hyaline casts. There is a remarkable absence of any hæmorrhagic zone round the necrotic areas. On the medullary side there are scattered patches of congestion only, and even these are few. There is a well-marked zone of small-celled infiltration at the periphery of the enclosed portions, and collections of leucocytes are scattered irregularly throughout them. In the necrotic areas the outlines of the tubules can be made out easily, but the epithelium and the glomeruli are completely necrotic and do not show any nuclear staining. The interstitial tissue is also necrotic and does not show any nuclear staining. The arteries and veins in and contiguous to the necrosed areas are thrombosed, but no thrombosis can be detected in any of the vessels lying farther away. The arteries are not thick-walled and are quite free from any proliferation of the subintimal connective tissue.

The liver did not present any areas suggesting focal necroses to the naked eye, and on microscopical examination no such areas can be seen. The softened central portion consists of liver cells much altered in shape and shrunken in size. Some are markedly degenerate and vacuolated, others still stain well and have well-preserved nuclei. The normal arrangement of the cells, however, is destroyed, and the capillaries can no longer be made out. Here and there remains of a portal space can be made out without any thrombosis in the vessels. The whole area suggests a post-mortem disintegration.

In the kidneys those portions of the cortex, which are not necrosed, still show well the normal arrangement, although the tubal epithelium shows the changes already described. These changes are indistinguishable from those met with in the so-called "nephritis of pregnancy"—a degenerative lesion of the tubal epithelium due to toxæmia. It has also been shown that hyaline or agglutinative thrombi are met with in the capillaries in many infective and toxic states (*vide* Welch[14]). On the other hand, cortical necrosis does not occur in the kidney of acute nephritis, however severe the lesion may be, nor in cases of corrosive sublimate poisoning in which the tubal epithelium may even show calcification. It seems probable, therefore, in this case (at all events) that the necrosis, involving as it does both epithelium and interstitial tissue, is the direct sequence of the extensive thrombosis present in the vessels. Apart from the lesions present in the renal epithelium, the rapid disintegration in the liver points to there having been a grave toxæmia, and it is to this toxin, whatever its nature, that both the degeneration of the tubal epithelium and the hyaline thrombosis are due. To the latter must be attributed the final necrosis of the cortex, which is in a state similar to that seen in anæmic infarction.

Upper Brook-street, W.

THE EFFECT OF ALTITUDE ON BLOOD VOLUME,

TOGETHER WITH FURTHER OBSERVATIONS ON THE BLOOD IN WARM-BLOODED AND COLD-BLOODED ANIMALS.[1]

BY GEORGES DREYER, M.D.,
PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF OXFORD;
AND
E. W. AINLEY WALKER, D.M.,
LECTURER IN PATHOLOGY IN THE UNIVERSITY OF OXFORD.

I.—A CONTRIBUTION TO THE STUDY OF THE EFFECT OF ALTITUDE ON THE BLOOD.

IT has long been known that the effect of living at high altitudes is to cause an increase in the number of red corpuscles per cubic millimetre of blood and an increase in the hæmoglobin percentage of the blood. The effects of living under permanently increased atmospheric pressure have not been fully followed out, but data exist regarding the effect of a descent from residence at a high altitude to a lower level.

Changes also occur in the blood volume of animals placed under novel conditions as regards altitude. Those changes are of a regular character, and follow definite laws. An analysis of the entirely admirable series of observations on the influence of high altitudes on the blood recorded by Abderhalden in 1902, which contain an almost inexhaustible wealth of information, has led us to the conclusion that the change of blood volume which occurs with a particular change of barometric pressure is proportional to the area of the body surface in different individuals of a given species. The blood volume of rabbits taken up from Basel (266 metres above sea level) and kept by Abderhalden at St. Moritz (1856 metres above sea level) still conforms to our formula, $B = \frac{W^{0.72}}{k}$. But k is now increased. That is to say, the blood volume is diminished by an amount exactly proportional to their body surface. For brevity we omit the long tables of calculations by means of which the value of n and k are determined from Abderhalden's figures. His 20 Basel rabbits calculated by the formula $B = \frac{W^{0.72}}{k}$ give a k of 2·43, while his 19 rabbits at St. Moritz had blood volumes which give a value for k of 2·72. This means a diminution of blood volume of 10·7 per cent. (or nearly 11 per cent.).

At the altitude of St. Moritz the hæmoglobin percentage shows an increase, and the number of red corpuscles per cubic millimetre undergoes a parallel increase. This change is at first due entirely to a rapidly occurring concentration of the blood, as is shown by the immediate rise in the number of red corpuscles and the hæmoglobin percentage (10 per cent. or more within some 24 hours). A similar immediate concentration can be seen in the figures obtained by Douglas, Haldane, Henderson, and Schneider in man on Pike's Peak and in a number of other published observations. But in Abderhalden's figures for rabbits, which had been at St. Moritz for from four and a half to eight weeks, the percentage hæmoglobin shows an increase from 11·74, the figure found at Basel, to 14·60. This is a percentage increase in hæmoglobin percentage of 25·1.

If the increase in hæmoglobin percentage were entirely due at this period to concentration of the blood, the blood volume should have been reduced by 20 per cent.; it was actually only reduced by 10·7 per cent.—that is to say, that of the percentage increase in percentage hæmoglobin 12 per cent. is due to the fall in blood volume (k rising from 2·43 to 2·72) and 13·1 per cent. is due to new formation of hæmoglobin. These together give the total increase in percentage hæmoglobin of 25·1 per cent., a decrease in blood volume of 10·7 per cent. and an increase of 11·7 per cent in the total hæmoglobin in St. Moritz rabbits as compared with the rabbits kept at Basel as controls. Abderhalden thought that the increased production of hæmoglobin at St. Moritz was only slight and not of great importance, but our calculations from his figures show that it amounted to 11·7 per

[1] Papers read at the meeting of the British Association for the Advancement of Science at Birmingham on Sept. 16th, 1913.

cent. of the total hæmoglobin, thus accounting for about one half of the increased hæmoglobin percentage found at St. Moritz.

This proves the occurrence of an active new formation of blood in the course of a temporary residence of some weeks' duration at a high altitude. Thus in animals examined at the stage of Abderhalden's St. Moritz rabbits we find that *about half* the increase in hæmoglobin percentage is due to concentration of the blood and about half to new formation of hæmoglobin and red corpuscles. But in animals examined within a day or two of their ascent to a high altitude the *whole* change is due to diminution of the blood volume, Similar conclusions can be drawn from an analysis of Abderhalden's figures for oxen and swine. In their recent work on Pike's Peak (3386 metres high—14,109 feet) Douglas, Haldane, Henderson, and Schneider state that "the increased percentage of hæmoglobin on Pike's Peak was apparently due in part, during the first few days, to concentration of the blood, but afterwards entirely to a large increase in the total amount of hæmoglobin." We maintain, however, that at first the increase is *entirely* due to concentration of the blood, and that afterwards it is partly due to concentration of the plasma and partly to increased formation of hæmoglobin. These observers further state that "along with this increase there was (except in the first few days) a slight increase in the blood volume." But we find that taking Abderhalden's observations on animals (observations carried out with the most minute accuracy and care) the blood volume was *never* increased, but was diminished by more than 10 per cent.

We can now take the matter a step further by investigating the *corpuscular richness* of the blood in Abderhalden's rabbits. The blood count in red corpuscles may be taken as an accurate measure of the hæmoglobin, since Abderhalden found that the hæmoglobin value per corpuscle was only very slightly increased, if at all, even after eight weeks at St. Moritz; and it certainly would not be altered after one day. Calculating, then, from six rabbits whose blood count had been determined at Basel, was again determined within one day of their arrival at St. Moritz, and then followed daily or at intervals until the last count on the day when they were washed out, we obtain the following results. After one day at St. Moritz the percentage hæmoglobin was increased from 11·77 to 13·80, an increase of 17·3 per cent. This corresponds to a decrease in blood volume of 14·7 per cent. After from 4½ to eight weeks at St. Moritz, when these animals were washed out, the blood volume and total hæmoglobin were determined. The blood volume was found to have decreased by 8·7 per cent. from its Basel value, and the total hæmoglobin had increased by 12·2 per cent. The increase in percentage hæmoglobin was from 11·77 to 14·46—that is, an increase of 22·8 per cent. Of this increase, 9·5 per cent. is due to the fall in the blood volume, and 13·3 per cent. is due to the new formed hæmoglobin. At the end of one day, however, at St. Moritz the percentage hæmoglobin is found to be increased from 11·77 to 13·80, an increase of 17·3 per cent., and since this can only have occurred by concentration of the plasma, the blood volume has diminished by 14·7 per cent. This concentration gradually undergoes a partial diminution *pari passu* with the new formation of hæmoglobin, so that at the end of the period of observation, when the new formed hæmoglobin amounts to 12·2 per cent. of the original total hæmoglobin, the blood volume is only reduced by 8·7 per cent. in these animals.

The next question is what takes place in rabbits brought back to Basel after a sojourn of from 4½ to 8 weeks at St. Moritz. The sequence of events may be stated as follows. When the animals were brought down again to Basel the blood diluted itself, and the blood volume reached the Basel normal in *four* days. The dilution did not occur so promptly after the descent as did the concentration after the ascent. In the first two days it was slight, but then became more rapid. But one cannot tell what access the rabbits may or may not have had to fluid during their return journey. At any rate, the blood volume has reached the normal for Basel after four days, and the blood constant is identical for the animals observed after four days, after five days, and after six to eight days respectively, being 2·43 for each set of observations (a total of 12 rabbits)—i.e., the same k as the k (2·43) for rabbits which remained at Basel throughout the investigation. This finding is further supported by the fact that after the third day and onwards the daily fall in *oxygen capacity* runs exactly parallel to the fall in percentage hæmoglobin. It is confirmed by calculating from the long series of rabbits in which the fall in percentage hæmoglobin and in red corpuscles per cubic millimetre was followed during the first five days after the descent. Within the first four days there is no appreciable diminution at all of the total oxygen capacity. That is to say, there is no recognisable disappearance of hæmoglobin from the blood. After this the excess of hæmoglobin which was produced at St. Moritz begins to disappear. It is almost all gone (within 1 per cent.) in the rabbits examined between 15 and 19 days from the date of descent, their percentage hæmoglobin being 11·84 against 11·74 in the controls, and their total oxygen capacity 11·60 as compared with 11·51 in the controls.

Douglas, Haldane, Henderson, and Schneider state that "on coming down from Pike's Peak the hæmoglobin percentage diminished much more rapidly than the total hæmoglobin, so that the blood volume was still further increased at first." These results in man, from three or four individuals, are totally at variance with the results obtained from Abderhalden's long series of experiments on rabbits. These observers also found that it required four weeks for the excess of blood volume to disappear. In rabbits it required only four days for the diminished blood volume to increase again to the normal. They found that the percentage hæmoglobin fell to normal much before the excess of hæmoglobin disappeared. But in rabbits after the first four days the fall in percentage hæmoglobin and in total hæmoglobin run parallel during the period of gradual return to normal. It is improbable that in these respects man differs so remarkably from other mammals. But all the disagreements are capable of explanation by the fact that the CO method was used for the determinations on man. At every point of divergence the fact that a proportion of the CO breathed must go to the extravascular hæmoglobin, along with the fact that this extravascular hæmoglobin is undergoing marked changes, first in the one direction and then in the other (first a steady increase and after the descent a steady diminution), is sufficient to explain the discrepancy in the results obtained. Indeed, it would have been possible to foretell that the results with the CO method would probably exhibit just these divergences.

II.—CONSIDERATIONS BEARING ON THE STUDY OF THE BLOOD AND VASCULAR SYSTEM.

The normal volume of the blood.—In mammalian animals the volume of the blood is proportional to the surface of the individual in any given species, and may be calculated from the formula $B = \frac{W^n}{k}$, where W is the weight of the animal in grammes, n is approximately 0·72, and k is a constant to be ascertained for each particular species. This statement we have shown, in association with Dr. W. Ray, to hold for a series of mammals both wild and tame—namely, rabbit, guinea-pig, mouse, wild rabbit, hare, and wild rat. And in response to criticism we have been able to confirm it absolutely for tame rabbits by an analysis of 126 independent observations collected from the literature. This analysis gave identically the same n as the n deduced from our own observations. In regard to birds, the other great group of warm-blooded animals, hitherto unpublished experiments carried out by us in association with Dr. H. K. Fry on fowls, pigeons, sparrows, and ducks, show that here also the blood volume is proportional to the surface. In these observations n has the value 0·70—0·72 in the formula $B = \frac{W^n}{k}$, and that this formula also accurately represents the surface area in these birds was proved by actual measurements of the surface in a large number of cases by means of the planimeter.

That the relation thus established between the blood volume of warm-blooded animals and the area of their body surface is associated with the homoiothermic character of these animals appears to follow from the results of observations carried out in the Department of Pathology at Oxford on cold-blooded animals by Dr. Fry and embodied in his still unpublished thesis. These observations were made on lizards and frogs, and show quite clearly that in both these animals the blood volume is neither proportional to the body surface nor to the body weight. But it varies as a power greater than unity (about 1·2) of the body weight, so that the volume follows the formula $B = \frac{W^{1\cdot21}}{k}$. This indicates the fact that in these cold-blooded animals the percentage

blood volume actually increases as the animal grows heavier, while in the warm-blooded animals it undergoes a steady diminution. The value of k as given by Fry's observations is 42·0 for frogs and 55·5 for lizards.

It is significant that in animals of such different shape as the lizard and the frog the value of n should be the same for both. This seems to indicate an underlying relationship to which we shall return on a future occasion.[2] Meanwhile, it may be stated that the value of n obtained by Fry is in agreement with the value of n as calculated by us from the old observations of Welcker and others on frogs. Their figures for frogs also give a k of about 42·0.

Further application of the surface relation.—In the course of our investigation of the blood volume of animals we had observed with interest that in those species which possessed a large blood volume the aorta was much larger than in species of a similar size which had smaller blood volumes. Accordingly we carried out a series of observations, in association with Dr. Ray, upon the sectional area of the aorta just above the semilunar valves. Here, again, we were able to show quite definitely that in both mammals and birds the sectional area of the aorta is proportional to the body surface and conforms to the formula $A = \frac{W^n}{k}$, where the value of n is 0·70–0·72. The sectional area of the trachea was also found to be proportional to the body surface. An interesting point now emerges from a consideration of our figures for guinea-pigs and rabbits. The rabbit has relatively a good deal more blood than the guinea-pig, and accordingly its aorta is relatively larger. On the other hand, it has much less hæmoglobin than the guinea-pig, but its trachea is very much larger, thus doubtless rendering easier the intake of oxygen.

A further point of interest may be mentioned here—namely, that in examining animals of different species we have found the ratio of the weight of the heart muscle to the total oxygen capacity of the circulating blood to be approximately constant from species to species in a number of cases.

Influence of sex.—As regards sex, we find that in the mammals which we have examined the blood volume is somewhat smaller (about 3 per cent.) in the female animal than in the male of the same weight. This relationship is, however, altered during pregnancy and in the puerperal condition, when the blood volume of the female is considerably increased. The sectional area of the aorta is also smaller in the female than in the male of corresponding weight, while so far as our observations go, that of the trachea is somewhat larger in the female than in the male. Thus the male which has the larger blood volume has a larger aorta, while the female, which has a somewhat lower percentage of hæmoglobin in its blood than the male, is provided with a relatively wider trachea for the admission of oxygen. This difference between the sexes within the same species is of the same character as the differences in the blood volume, aortic cross section, hæmoglobin percentage and tracheal area existing between different species, already pointed out above, in comparing the rabbit with the guinea-pig. In drawing attention to these facts we intentionally omit for the present any reference to certain other factors which we know to be of importance—namely, the velocity of the blood flow, the frequency of the heart beat, the rate of the respiration, and the amount of the respiratory exchange.

Influence of age and species.—As regards age, by which we here imply the progressive increase of the animal in size and weight up to full growth, it may be stated that in any given species younger and lighter animals possess a lower percentage of hæmoglobin both in their circulating blood and in their muscles than the older and heavier individuals. And since, as Ranke showed, the muscles increase more than in proportion to the increase in body weight, it follows that the muscle hæmoglobin increases relatively much more rapidly than the weight of the animal. This fact is, as we have previously pointed out, an important source of error in the application of the CO method for the determination of blood volume.

In different species it is strikingly evident that the mode of life and muscular activity of the species is a factor of importance in determining the amount and the distribution of the hæmoglobin in the body. Animals which have a high hæmoglobin percentage in their blood have in general a high hæmoglobin percentage in their muscles, and in consequence dark flesh, while those which have a lower hæmoglobin percentage in the blood have also a lower percentage in the muscles and have pale or white flesh. This is seen on comparing wild rabbits with tame rabbits, hares with wild rabbits, ducks with fowls, and adult animals with younger animals of the same species. Moreover, on comparing the hare with the wild rabbit it is seen that the former animal, which exhibits both great endurance and remarkable speed, has a higher hæmoglobin percentage, darker muscles, a heavier heart, and a larger aorta than the latter, whose natural mode of life calls for less exhibition of long maintained muscular effort and staying power. The hare has more than double the blood volume, 30 per cent. more hæmoglobin in its blood, and about three times as much heart muscle as a wild rabbit of the same size. Similar facts apply to particular muscles and groups of muscles in different animals. The wing muscles of birds which fly are always dark in different degrees, while those of fowls are pale. But in all animals the heart, diaphragm, and intercostal muscles are always dark.

The regulation of the volume of the blood.—Under normal conditions the volume of the blood of mammals is very delicately adjusted. The restoration of volume, which, as is well known, quickly occurs after hæmorrhage or transfusion (whether of defibrinated blood or of isotonic saline solutions), begins *immediately*. It is already recognisable by a definite and measurable change in the hæmoglobin percentage when only a very small percentage of fluid has been removed or introduced. This fact adversely affects the value of many of the experiments which have been carried out on bleeding and transfusion, since it has evidently escaped due recognition. The application of an elastic bandage to a limb has practically the effect of a transfusion of blood by considerably increasing the volume of the blood circulating in the now diminished vascular area. Accordingly it is found that a rapid concentration of the blood indicated by an increase in the hæmoglobin percentage occurs and is already recognisable within a few minutes of the application of the bandage. On removing the bandage the blood quickly restores itself to its former volume by a process of dilution. The effect of cold or warmth applied to the surface is largely comparable to the effect of applying an elastic bandage or removing one from from a limb. By its effect upon the superficial vessels it leads to a concentration or dilution of the blood as the case may be.

In further experiments the effect of certain chemical substances on the volume and concentration of the blood has been investigated. In many experiments on the blood and respiration it has hitherto been tacitly assumed that the blood volume undergoes no significant alteration during the period of observation. We find, however, that this is not the case. The presence of an increased amount of carbon dioxide in the respired air produced by breathing into a confined space quickly leads to a dilution of the plasma and an increase of blood volume which may amount to 10 per cent. or even more. This is a new factor which will come into account in interpreting many of the experiments carried out by respiratory methods. The inhalation of oxygen, on the other hand, leaves the blood volume unaltered. The administration of amyl nitrite which causes vascular dilatation also leads to an immediate dilution of the plasma. This observation renders it unlikely that an abiding fall in the blood pressure can be brought about under normal conditions by the production of active vaso-dilatation. The introduction into animals of chloral hydrate in quantities sufficient to cause anæsthesia produces rapid concentration of the blood with a corresponding diminution of blood volume. This has been demonstrated not only by estimating the increase which occurs in the hæmoglobin percentage, but also by direct determination of the blood volume by means of washing out experiments. The degree of concentration varies with the dosage—a fact of importance in relation to the pharmacological action of this drug, and one which renders it an unsuitable anæsthetic to employ in work upon the blood and circulation. On the other hand, ether anæsthesia leaves the volume of the blood unaltered.

[2] This relationship in the frog is a relationship to the mass of the osteomuscular system, which also follows the formula $M = \frac{W^{1·21}}{k}$.

VERONAL POISONING.[1]

BY WILLIAM HENRY WILLCOX, M.D., B.Sc. LOND., F.R.C.P. LOND., F.I.C., D.P.H., &c.,
PHYSICIAN TO ST. MARY'S HOSPITAL, LONDON; SENIOR SCIENTIFIC ANALYST TO THE HOME OFFICE, ENGLAND.

THE chemical formula of veronal is—

$$\begin{matrix} C_2H_5 \\ C_2H_5 \end{matrix}\!\!>\!C\!<\!\!\begin{matrix} CO\ HN \\ CO.HN \end{matrix}\!\!>\!CO.$$

It is chemically described as malourea, or diethyl malony urea, or diethyl barbituric acid. "Veronal" is a registered trade name, and another name of the same character also used for this compound is "hypnogen." Veronal is a white crystalline powder, odourless; melting point, 191° C. It has a bitter and somewhat nauseous taste, it has an acid reaction to litmus, and it is only slightly soluble in cold water. At 20° C. 1 part is soluble in 146 to 147 of water, at 90° C. 1 part is soluble in 23 of water, and at 100° C. 1 part is soluble in 15 of water. Veronal is easily soluble in alkaline solutions. It is soluble in alcohol, ether, acetone, or acetic ether, but it is not readily soluble in chloroform. Veronal was discovered in 1902 (Professor E. Fischer and Professor J. Mering). It was prepared [2] by treating diethyl malonic acid ester with urea and sodium ethylate. Another good method of preparing veronal is by treating diethyl malonyl chloride with urea.

Veronal has for the past seven years been very widely used in this country as a hypnotic. Indeed, its use has become well known to the public, so that there is reason to believe that commonly the drug has been taken for insomnia without the advice or prescription of a medical man. It is undoubtedly a powerful hypnotic. Messrs. Merck and Bayer, the introducers of the drug, claim that they have always understood that it was "an exceedingly potent hypnotic," and that they have always laid stress on the danger of exceeding the therapeutic doses. A letter to this effect from the Bayer Company, Limited, appeared recently.[3] There is no doubt that soon after its introduction veronal became popular as a hypnotic, and it is quite certain that its exceedingly potent action was not fully appreciated by the medical profession and still less so by the public. It is spoken of as "a sleep-producing drug of a relatively harmless character"[4]; and Professor Bradbury [5] has described it as "one of the quickest, safest, and most reliable hypnotics." These statements, of course, referred to therapeutic doses, but it is to be feared that it has been sometimes assumed that because the drug is harmless in therapeutic doses it may be given in doses considerably in excess of this. It is most important that the medical profession and the public should realise that the therapeutic dose cannot be exceeded with safety except in very special cases.

The therapeutic dose of veronal for an adult is given in the British Pharmaceutical Codex for 1907 as 5 to 15 grains; while in the latest edition of that work (1911) the dose is given as 5 to 10 grains, an indication that perhaps the potent action of the drug had not been fully recognised in 1907. The Bayer Company in a recent pamphlet on veronal give the dose for an adult as 5–10–15 grains, but they state "it should be clearly understood that in ordinary cases of insomnia the 5 grain dose is quite sufficient for an adult, and that the dose should only be repeated after a reasonable interval." In a single therapeutic dose it usually acts fairly quickly, producing sleep within an hour or so, and the sleep lasts for several hours.

Toxic symptoms may occur after the administration of veronal, and these may be the result of: (1) a special idiosyncrasy causing a susceptibility to a small or moderate dose; (2) an excessive dose having been taken; (3) repeated small doses as in the veronal habit. The toxic symptoms which occur after a single large dose are drowsiness, headache, and sometimes ataxy accompanied by a reeling gait. The patient falls into a deep sleep from which he can only be roused with difficulty. In severe cases the sleep deepens into coma, and the patient becomes cyanosed with rapid and often stertorous breathing. In this stage it is very common for a marked rise of temperature, even to 103° F. or more, to occur, and a physical examination of the lungs will probably show areas of dulness on percussion, increased vocal resonance, bronchial breathing, and moist sounds. In other words, all the clinical signs of pneumonia will be present. These signs will be accompanied or followed by those of a general œdema of the lungs, such as moist bubbling râles all over. It is quite easy for a severe case of veronal poisoning to be mistaken for pneumonia, and I have known the mistake made on several occasions. When the condition of deep coma and pulmonary symptoms develops after the taking of a large dose of the drug it is uncommon for recovery to occur. Sometimes a condition of coma and high temperature will last for as long as four days before death supervenes, but after a very large dose death may occur in less than 24 hours.

It is said that digestive disturbances, nausea, and vomiting occur from the drug. These undoubtedly occur in chronic veronal poisoning (veronal habit). In my experience they are uncommon in cases where a single large dose is taken. Skin rashes have been described as a result of veronal. These are erythematous in type and of a rubeoliform or scarlatiniform character. It is stated that occasionally urticarial rashes occur and also extreme pruritus and œdema of the face. In my experience skin rashes are not common after veronal. It is said that urinary disturbances, such as suppression, albuminuria, hæmatoporphyrinuria, and hæmaturia, may occur from the drug. I have not observed these symptoms except slight albuminuria. In several severe cases of veronal poisoning I have noticed a remarkably free excretion of urine, but often the urine has to be withdrawn by the catheter when the patient is in a comatose condition.

In chronic veronal poisoning (veronal habit) the patient often develops an abnormal mental condition, visual hallucinations are common, and also delusions may occur; the whole mental balance may be upset and a sort of double self exist subjectively. In these cases tremors and marked ataxy are common, and the condition may resemble cerebellar disease. The speech is often affected, and thick and indistinct, and disturbances of sight may occur. The gait in these cases is commonly quite reeling, similar to that of a drunken person. The veronal habit causes a complete disorganisation of the moral sense, just as is the case with the morphia and cocaine habits.

In cases of renal disease veronal is much more toxic than with normal patients. Also it is important that constipation should be avoided if the drug is being given frequently, since otherwise toxic symptoms may develop. In these conditions a cumulative action may occur if it is given in therapeutic doses continuously.

Fatal dose.—Cases of death have been recorded after taking veronal, even with such small doses as 10 grains. In these cases probably other factors were present, and death was not entirely due to the drug. In a healthy adult it may be taken that a dose of about 50 grains would be dangerous, and might be regarded as an average minimum fatal dose. It is well known that much larger doses have been taken without death resulting, but in these cases serious symptoms such as deep coma have occurred, and there has been grave danger. On the other hand, fatal cases are recorded from doses of 1 gramme (15 grains).

It must be remembered that in the recorded cases of fatal veronal poisoning the patients have often been the subject of some other disease, or of some other form of poisoning, such as alcohol, morphine, &c., and the veronal taken may have not been entirely responsible for the fatal issue. Also it must be borne in mind that in fatal cases of veronal poisoning it is usually almost impossible to say what was the exact dose taken, since the early onset of coma usually prevents any information being obtained from the patient. A reference to the cases of which details are given will illustrate this.

Tolerance to veronal.—Undoubtedly tolerance may be established in some cases, but a great tolerance comparable to that in morphine and cocaine takers does not occur. Even in cases where patients are accustomed to taking the drug it must be accepted that a dose of about 50 grains is likely to produce deep coma which may be followed by death.

Treatment of acute veronal poisoning.—If the patient is

seen soon after taking the drug—i.e., within four hours—it will always be most advisable to pass into the stomach a soft stomach tube to which is attached a piece of plain rubber tubing about 3 feet long, in the end of which is a glass funnel. There is no risk in the careful passage of a soft stomach tube. The mouth should be kept open by means of a suitable gag while the tube is being passed, and the passage of the tube down the œsophagus is readily brought about by first guiding the end with the left fore-finger placed in the mouth. About 20 inches of stomach tube should be passed beyond the teeth, the tube being gently pushed down with the right hand. During the process of passing the stomach tube the mouth should be in the mid-line of the body, the head not being rotated. When the tube is in the stomach no air will issue from its funnel end. Some warm water should now be placed in the funnel, and the funnel raised, so that the tube becomes filled with water. Before the funnel is empty it is quickly depressed, and this will start a syphon action, so that the contents of the stomach can be syphoned out. These should be carefully reserved for future analysis. When the stomach has been emptied as completely as possible it is very advisable to wash it out thoroughly by introducing about 2 pints of warm water and then syphoning this off. This washing out should be repeated three or four times and the stomach emptied as completely as possible. Before withdrawing the tube about 1 pint of hot strong coffee with some milk in it, and an ounce of castor oil or other suitable aperient, should be introduced and left in the stomach. The stomach tube is now withdrawn.

The above details have been given because it is sometimes imagined that there is risk in washing out the stomach in cases of veronal poisoning. There is no risk if the operation is carefully performed within a few hours of taking the poison. The risk of not doing this is infinitely greater. After six hours or so from taking the poison most of it will probably have passed from the stomach into the intestine, so that washing out of the stomach is not likely to be of much avail in removing the poison. Unless the patient is *in extremis* the stomach tube may often then be passed with advantage and a rapid washing out performed, strong coffee being introduced as described above.

Cardiac stimulants should be given, such as strychnine hydrochloride gr. 1/30, with digitalin gr. 1/100 every four hours. Warm normal saline should be given subcutaneously, and also rectal injections of normal saline containing 4 per cent. of glucose should be given in amount of 15 oz. every four hours. If there is much cyanosis oxygen should be given, and when the pulse is feeble the oxygen may with advantage be passed through a wash-bottle containing absolute alcohol, since the combination of oxygen and alcohol vapour is a valuable cardiac stimulant. During the comatose state attention must be paid to the bladder, the urine being drawn off by a catheter if necessary. Any urine passed must be carefully preserved for analysis. If urine is not being excreted freely injections of the hypodermic solution of caffeine may be given every four hours. Other stimulants that may be given if necessary are camphor and pituitary extract hypodermically.

It must be remembered that in acute veronal poisoning the state of coma which comes on soon after taking the drug may last several days. It will therefore be necessary to feed the patient. Warm milk, and milk and coffee may be given every four hours, either by the stomach tube or by a nasal tube carefully passed.

Post-mortem appearances.—Marked cyanosis is often present at the time of death, and this may persist after death, there being bluish discolouration of the lips and face, and also of the finger-nails. Post-mortem staining is usually well marked. The heart usually shows marked dilatation, this condition affecting the cavities of both sides. Usually the dilatation is more marked in the right auricle and ventricle than in the corresponding cavities on the left side. The great veins are full and the blood is often fluid. The air passages are congested and contain mucous exudation. The lungs show almost always marked hypostatic congestion and œdema in their dependent parts, and portions so affected commonly sink in water. Frequently patches of pneumonic consolidation are present in the lungs, and lymph may be present on the pleural surface of these areas. The pneumonic areas may be quite extensive, and they are to be distinguished from the general hypostatic congestion and œdema above mentioned. No characteristic changes occur in the stomach and intestines. The brain and abdominal viscera usually show marked congestion.

In conclusion, it may be said that the post-mortem signs of veronal poisoning are not specially characteristic. They are those of death from gradual heart failure, complicated by œdema and hypostatic congestion of the lungs. Such signs may be commonly found in death from natural causes.

Toxicological analysis.—There are no very characteristic chemical tests for the drug. Veronal gives well-marked crystals which are not readily soluble in water, but readily soluble in weak caustic soda solution. The melting point of veronal, 191° C., is very useful for identification, but it is necessary that it be isolated in a pure condition, otherwise its melting point will not agree with the theoretical. Re-crystallisation once or twice may be necessary before a constant melting point is obtained, and sometimes purification by treatment with blood charcoal is necessary. The amount isolated from a given case may be sufficient to admit of purification and determination of the melting point, but often the quantity of poison found is too small to permit of this. If a substance is isolated which is crystalline and identical in melting point with veronal, valuable confirmation is obtained by mixing the substance found with veronal and taking the melting point of the mixture. This will be unaltered if the substance found is veronal.

Veronal solution gives no precipitate with the reagents commonly used as alkaloidal precipitants. Veronal solution if boiled with solution of caustic potash (20 per cent.) is not decomposed, and the addition of Nessler's reagent gives no brown colouration. Veronal in the solid form if fused with caustic potash gives a nasty rancid smell. If the tube is cooled and water is added and then Nessler's reagent a well-marked brown colouration is produced. Veronal solution, if treated with two drops of dilute nitric acid and then with Millon's reagent, gives a white gelatinous precipitate, soluble in excess of the reagent.

Veronal is extracted from viscera by taking a given weight of the organ (about 120 grm). This is cut up finely and treated with 95 per cent. alcohol, just acidified with acetic acid. The extraction with alcohol is continued for 24 hours at 35° C. The alcoholic liquid is poured off, and the residue is treated with fresh alcohol as before. Four extractions are made. The alcoholic extracts are mixed, filtered, and evaporated to a syrupy consistence. Absolute alcohol (about 200 c.c.) is now added, and the mixture allowed to stand for a short time. It is then filtered, and the filtrate is evaporated to a syrupy consistence. The liquid is now taken up with water and the turbid mixture is filtered. The filtrate should be concentrated by evaporation below 35° C. to about 15 c.c. If the liquid is not highly coloured it may be extracted with ether (two volumes) successively for four times. The ethereal solutions are filtered, mixed, and gently evaporated in a weighed glass dish. The residue will contain the veronal present. It may be white and crystalline, but usually there is some brown tint, and further purification may be necessary.

Where the aqueous extract of the viscera is much coloured it is better to treat it with slight excess of lead acetate; the mixture is filtered and the excess of lead acetate removed by precipitation with sulphuretted hydrogen; the liquid is again filtered and concentrated by evaporation in a current of air to about 15 c.c. The liquid thus obtained is extracted with ether as above described. Any veronal present will be obtained in a fairly pure state. The residue, purified if necessary, is carefully tested for veronal by the above-mentioned tests.

Veronal is a poison which is distributed fairly evenly throughout the body; thus the abdominal viscera do not appear to have that selective action for the drug which they show with arsenic and some of the alkaloidal poisons. It is a drug which is rapidly excreted by the kidneys, and in a fatal case of veronal poisoning, where the patient has lived for 24 hours or more after taking the poison, it is probable that a considerable quantity will have been excreted in the urine. It follows, therefore, that the amount found in the whole body after death will not represent all the poison taken. In fatal cases of veronal poisoning, where death occurs after 24 hours, something like 40 to 50 per cent. of the poison will probably have been excreted in the urine before death. It is always most important that the urine excreted should be saved for analysis.

Extraction of veronal from urine.—About 200 c.c. of urine are taken. If a larger quantity is available this may with advantage be concentrated to 200 c.c. by evaporation at a low temperature. The urine is treated with a slight excess of acetate of lead solution, and the mixture after standing is filtered. The excess of acetate of lead is precipitated by sulphuretted hydrogen and the liquid is filtered. The filtrate is evaporated at a low temperature to about 60 c.c., a little blood charcoal is added, and the mixture filtered after standing a few hours. The filtrate is concentrated by evaporation at a low temperature to about 30 c.c. This is extracted with double the volume of ether three times, the ethereal extracts are mixed, filtered through a dry paper, and are evaporated to dryness at a low temperature. The crystalline residue is submitted to the tests for the drug, and the crystals are carefully compared with those obtained by evaporation of an ethereal solution of veronal.

Statistics of veronal poisoning.—A table is appended showing the returns of the Registrar-General for deaths from veronal poisoning occurring in England and Wales up to 1910. The later returns are not yet published. By the kindness of three coroners of large districts—viz., Mr. C. Luxmore Drew, Mr. W. Schröder, and Mr. G. Vere Benson—I am enabled to give up to date the cases of veronal poisoning in their respective districts. Statistics are very valuable as giving an indication of the frequency of cases of veronal poisoning, but it must be remembered that (1) cases of death which are really due to veronal poisoning may be overlooked and mistaken for pneumonia or other condition producing coma; (2) often veronal may be an accelerating factor in causing death, but some other toxic influence or disease plays an even more important part in bringing about a fatal issue, so that in some cases where "veronal poisoning" is the alleged cause of death it cannot be fairly regarded as being entirely responsible.

The following recent cases, which have been investigated by Dr. B. H. Spilsbury, of St. Mary's Hospital, and myself, are of interest and show the importance of considering the details of each case.

CASE 1.—Female, aged 27. The patient was probably addicted to alcohol. She was found unconscious in her bedroom, and death occurred after 42 hours. Empty bottles which had contained veronal tablets were found in the room. The post-mortem examination showed bright red post-mortem staining and cyanosis of the finger nails. The heart showed dilatation of all the cavities and brown atrophy of its muscle. The lungs showed marked œdema and hypostatic congestion; portions sank in water. *Verdict* of coroner's jury: "Death from veronal poisoning." There was no knowledge of the quantity of the drug taken.

CASE 2.—Female, aged 60. The patient was addicted to the taking of veronal, trional, and morphine. She was comatose for a few hours (at most eight) and died. In the bed was found a hypodermic syringe which contained morphine. An empty veronal bottle was found in the bedroom. A recent hypodermic puncture was present on the left thigh. The heart showed dilatation. The lungs showed hypostatic congestion and œdema. A large malignant growth was present in the stomach, and a scirrhous growth was present in the right breast. *Verdict*: "Death from veronal and morphine poisoning." In this case it is doubtful if veronal really played any important part in causing death.

CASE 3.—Male, aged 54. The patient had suffered from tabes dorsalis for two years. He was found dead in his dressing-room two hours after being seen by his wife in a conscious condition. A tumbler was found in the room containing a small quantity of veronal. The evidence in this case showed that the deceased could not have taken more than 20 grains of the drug, and probably much less was taken (about 5 grains only). The post-mortem signs showed dilatation of the heart and brown atrophy of its muscle. The lungs showed œdema and hypostatic congestion. *Verdict*: "Syncope from heart disease accelerated by veronal taken to produce sleep while patient was suffering from tabes dorsalis." In this case it is doubtful if the drug was a factor in causing death.

CASE 4.—Male, aged 37. The patient was found in his bedroom unconscious, and he remained comatose for about 78 hours before death. He was cyanosed and had all the clinical symptoms and physical signs of acute pneumonia. The temperature was from 100° to 105° F. the last two days. An empty bottle which had contained veronal tablets was found in the bedroom. The deceased was known to be addicted to the drug. Post-mortem examination showed marked post-mortem staining, dilatation of the heart, and hypostatic congestion and œdema of the lungs. *Verdict*: "Death accelerated by veronal poisoning." In this case probably a large dose was taken, but no exact evidence could be obtained.

CASE 5.—Female, aged 38. The patient suffered from an adherent pericardium with calcification. There was marked ascites and œdema. She became unconscious, and died after about 13 hours. Dilatation of the heart and hypostatic congestion and œdema of the lungs were present. The evidence in this case showed that probably 125 grains of medinal were taken. *Verdict*: "Death from heart disease, accelerated by medinal, taken with suicidal intent."

CASE 6.—Male, aged 39 years. The patient was found in a comatose condition, and died after being in a state of coma for about 80 hours. Post-mortem examination showed dilatation of the heart, and the lungs showed hypostatic congestion and œdema with patches of acute broncho-pneumonia. Veronal was found in the urine. Two empty tablet bottles were found in his bedroom. The deceased was known to be a veronal taker. *Verdict*: "Death from heart failure and pneumonia, accelerated by veronal poisoning." In this case there was no evidence as to the quantity taken. The deceased was suspected of being addicted to alcoholic excess.

CASE 7.—Female, aged 42. The deceased had threatened to poison herself by veronal. She was seen alive at 2 P.M., when she said she was going out for a walk. She was found dead in bed 20 hours afterwards. Post-mortem examination showed marked post-mortem staining and cyanosis of nails and lips. There was marked dilatation of the heart. The lungs showed hypostatic congestion and œdema; also there were patches of acute broncho-pneumonia in both lungs. *Verdict*: "Death from veronal poisoning (suicidal)." There was no evidence of the exact dose taken, but it was probably over 100 grains. (125 grains of veronal were known to have been purchased three weeks before death.)

CASE 8.—Male, aged 56. The patient had a fall of over 20 feet, fracturing the sternum and four ribs. He died about 48 hours afterwards. After the injury he was given therapeutic doses of paraldehyde and veronal, which were prescribed by his medical man. The heart showed dilatation and fatty degeneration of its muscle. The lungs showed hypostatic congestion and œdema. *Verdict*: "Death from shock following injuries accelerated by paraldehyde and veronal taken as hypnotics." In this case it is extremely doubtful if death was in any way accelerated by veronal.

CASE 9.—Male, aged 62. The patient took 53 grains of veronal. He became comatose, and on examination was found cyanosed, with temperature of 103° F., respiration 66, and rapid, feeble pulse. There was marked dulness over the whole of the upper lobe of the left lung, with crepitations and marked tubular breathing. He was treated for veronal poisoning and made a complete recovery. The coma lasted about 24 hours. The recovery in this case was remarkable, as it does not usually follow such very grave symptoms as were observed.

CASE 10.—Male, aged 28. A post-mortem examination showed some dilatation of the heart. The lungs showed hypostatic congestion and œdema and a small patch of pneumonia in the lowest lobe of the right lung. Chemical analysis showed veronal to be present in all the organs examined. The amount calculated as being present in the whole body was 75 grains. The evidence in this case showed that the deceased had taken a large dose of veronal, after which he rapidly became comatose and died after about 32 hours. Probably in this case a dose was taken of something like double that found in the body. *Verdict*: "Death from veronal poisoning, but there was no evidence to show how it was administered."

Medinal is the mono-sodium salt of veronal. It is very soluble in water and is therefore more rapid in action. Its toxicology is otherwise exactly similar to that of veronal.

Veronal, by its bitter taste and insolubility in aqueous solutions, could not easily be administered to a normal person in a poisonous dose without the taste being recognised; also the gritty insoluble particles might be detected. Medinal, though very soluble, has a bitter, nauseous taste which would almost certainly be recognised by a normal person taking it. The alkaline nature of medinal causes the drug to alter the colour of wines such as hock, &c., and this change in colour might arouse suspicion were any attempt made to administer the drug in this way unknown to the taker.

Proponal is dipropyl barbituric acid. It is more poisonous than veronal, but otherwise its toxicology is similar.

Luminal is diphenyl barbituric acid. It is more poisonous than veronal, but otherwise its toxicology is similar.

Preventive measures.—Veronal and its derivatives and allied substances are undoubtedly very useful therapeutic agents when carefully prescribed. It is most important, however, that powerful hypnotic drugs of this character should only be taken with the knowledge and consent of a medical practitioner and on his written prescription. It

would also be advisable if the dispensing of such prescription were not repeated without the written sanction of the medical man. The frequency of cases of veronal poisoning in this country has caused His Majesty's Privy Council to approve of the following addition to the Poisons and Pharmacy Act of 1908: that "diethyl barbituric acid, and other alkyl, aryl, or metallic derivatives of barbituric acid, whether described as veronal, proponal, medinal, or by any other trade name, mark, or designation, and all poisonous urethanes and ureides," ought to be deemed poisons within the meaning of the Pharmacy Act, 1868, as amended by the Poisons and Pharmacy Act, 1908, and ought to be deemed poisons in Part II. of the Schedule of Poisons to that Act. The effect of this resolution is that veronal and the other substances named and included in it can only be sold by a qualified pharmacist, and that all of these substances must be labelled "Poison," and must bear the name and address of the vendor.

The dangers from veronal poisoning are to some extent safeguarded by this valuable addition to our legislature, but the best safeguard of all will be a loyal coöperation of pharmacists with the medical profession in protecting the public from the abuse of drugs which have a potent though useful therapeutic action.

Welbeck-street, W.

A CLINICAL STUDY OF THE CHIEF FUNCTION OF THE PERITONEUM.[1]

BY JOHN HOWELL, M.B., B.S. LOND., F.R.C.S. ENG.,
HONORARY SURGEON TO THE CHELTENHAM GENERAL HOSPITAL, ETC.

THE chief function of the peritoneum is that of a "perienteric trap for the reception and annihilation of micro-organisms which *constantly* and *normally* (i.e., without producing symptoms) permeate the intestinal wall." It is part of the duty of certain organs intimately connected with the peritoneal cavity, of which the liver, stomach, and the intestines are the chief, to excrete the toxic products formed therein, including, in times of stress, the bacteria themselves, with the minimum risk of contamination to the remainder and more important parts of the body.

In animal life the cœlom is next in antiquity to the archenteron or primitive alimentary canal. When the organism consisted only of an outer layer, ectoderm, protective, sensitive, and reproductive, and an inner, endoderm, digestive and absorptive, the even distribution of nutritive material was a simple matter. When, however, a third layer, mesoderm, was developed, primarily for support and locomotion, secondarily for reproduction, any further progress in usefulness of this layer would be considerably hampered if its proper supply of nutriment continued to depend upon a correspondingly complex evagination of the alimentary canal amongst its cells. This difficulty would be solved by cleavage of the mesoderm into an inner thin layer, the splanchnopleure, and an outer layer, the somatopleure, with a cavity between (the cœlom) containing fluid kept in motion by the movements of the organism. Not only did this cavity serve as a nutriment distributor, but it also became a receptacle for the products of metabolism; the cavity was therefore placed in direct communication with the exterior. In addition the reproductive cells were shed into its interior and thus found an easy exit. In the trochosphere larva of the polychæta we find a large perienteric cavity, which is not the cœlom (it is, in fact, the original blastocele), and for reasons which I cannot enter into here it is clear that none of the above functions are required of it, for it is practically a cœlenterate, the mesoderm being relegated to the very hinder end near the anus. Why, then, this persistence of the blastocele? I suggest that here we get the first glimpse of the utility of a perienteric cavity as a trap for organisms. I may reasonably assume that along with the food a large number of cocci, bacteria, and protozoa would pass into the alimentary canal of this animalcule, some of them actively hostile. With a large number of these the cells of the endoderm would be able to deal, but it can be imagined that from the number or virulence of the invading organisms the resistance of this first line of defence would be not infrequently overcome. It is important that the contents of the canal should be rid of this contamination before they reached the hinder end, for here, surrounding the endoderm, are the mesodermic bands which contain the elements essential, not only for the development of the adult polychæte, but, in the form of reproductive cells, for that of countless numbers of annelids. Any bacteria, therefore, which succeed in defeating or eluding the endodermic cells only break into, they may even be enticed into, a lethal chamber containing lethal fluid, which frees itself of toxins through the primitive "pronephridia."

To proceed a step further on the road of evolution, let us consider the cœlom of the earthworm, with which you are no doubt familiar. It is strikingly large, though the distribution of nutritive material and conveyance of the products of metabolism are performed by an elaborate blood circulatory system, whilst the formation of reproductive cells has been relegated to one or two segments only. We have to explain why—(1) the cœlomic cavity is relatively so large, a characteristic of this and allied types; (2) it communicates directly with the exterior by dorsal pores after the eighth segment; (3) dorsal pores are not found in the first eight segments; and (4) in spite of the existence of a circulatory system the nephridia still open by bell-shaped ciliated mouths directly into the cœlomic cavity.

To take the last first, it might be urged that the organism did not as yet depend upon the circulation entirely for the conveyance of metabolic products to the cells of the nephridial tubules, and that, even if it did, the funnels had not had time to degenerate; to which my reply is that tubules in direct communication with the exterior open by funnel-shaped mouths into the cœloms of the various orders right up to and including vertebrates, even the aminota, and this in spite of a continually improved and elaborated circulatory system. The obvious reason is that the cœlomic fluid contains material which is better conveyed directly to the purifying cells of the nephridial tubules than through the systemic circulation. In the case of the earthworm it might still be true that a large part of the products of metabolism is thrown directly into the cœlom and then extracted by the nephridia, but even a cursory examination of the higher orders would show that in their case this could scarcely be. The poison which contaminates the cœlomic fluid is not the result of metabolism, but of bacteria which have permeated the intestinal wall; the cilia of the funnels guide this fluid down the tubule; the water, or part of it, now purified, is reabsorbed by the cells of the tubules into the general circulation, so that the cœlomic fluid is cleaned of its poisons without risk to the body tissues. The earthworm has a partiality for what the gardener calls "fat stuff"—i.e., material teeming with bacteria of all kinds and grades of virulence—passing immense quantities of it through its alimentary tract in the course of its lifetime. I would have you believe that the single layer of ciliated epithelium and a few layers of chloragogen cells are not the only defence against the entrance of these hordes of bacteria into the body tissues. If they were, no earthworm would survive a day, and the result to the community would be appalling. Darwin has pointed out that these animals are an important agent in the formation of mould; I venture to add, in its purification also. On the contrary, they pass in their myriads, some killed, some maimed in the struggle with the first line of defence, into the cœlomic cavity, where they are effectually dealt with by the amœboid cells and the bactericidal fluid of the cœlom. The particulate relics of both sides are swept out through the dorsal pore, not down the nephridial tube, the mouth of which is guarded by cilia which prevent the blocking up by such particles of the delicate slender tubule. The cœlomic fluid is purified in the way I mentioned above. This, I think, explains the large size of the cœlomic cavity in these scavengers, and the presence of the dorsal pore behind the pharyngeal segments, which, owing to the fact that there is no absorption by the thick-walled pharynx, and therefore no stagnation of foodstuff, would not require one. And herein lies the keynote of my theory. Around that portion of the alimentary tract where foodstuff containing bacteria is *stagnated* for the purpose of *absorption*, nature has developed a fluid-containing cavity designed for

[1] Paper founded upon the introduction to a discussion before the Medical Society of London, May 19th, 1913.

the reception and destruction of micro-organisms which thus find an opportunity to permeate its wall, with an apparatus for its own purification so arranged that its poisonous excretions shall not contaminate the systemic tissues. This is true of the whole range of animal life, including the highest vertebrate, man, in whom this perienteric trap, so far from degenerating, has become more complicated, yet not less efficient, than that of the earthworm. The machinery for its purification is less obvious, perhaps, only because it has been less studied.

The progressive adaptability to its environment evolved in the animal has necessitated, or at least has been accompanied by, a complex evolution of the cœlom as well. Its channels of excretion, direct and obvious in the lower animals, have become indirect and obscure in the higher series. The nephridia, the pronephric and mesonephric tubules gradually disappear and give place to other more elaborate and more complicated channels which, however, conform to the primitive and invariable rule that they excrete the cœlomic toxins without risk to the tissues of the somatopleure. The anatomical disposition of these will require time, patience, and ingenuity to unravel, to such an extent has Nature clouded their outlines in her desire to have many functions performed by one organ. In the amphioxus we see excretion carried out, on the one hand by the primitive method of tubules, on the other through a specialised portion of the body wall. Much as I should like to have done so, I do not intend on this occasion to trace the gradual evolution of these indirect channels through the rest of the vertebrate series except to hint that the original function of the air bladder of fishes was not concerned with hydrostatics; that the lungs of amphibia and the air sacs of sauropsida subserve another and older purpose than that of respiration, and that when the diaphragm shut out the lungs from the mammalian cœlom the omentum was already in an advanced state of development; it only remained to detach its veins from the hepatic and connect them with the portal. To this day the human lung has not forgotten its most primitive function of excretion, as witness pneumonia, the bronchitis of typhoid and of gastro-enteritis, but it is now subsidiary to the omentum, *par excellence* the police and sanitary officer of the human cœlom. The human alimentary canal is constantly infected with millions of pathogenic and other bacteria. Let us follow the wanderings of an army of staphylococci which has been swallowed from, say, a suppurating antrum. For the present we will leave out of count the fact that one army follows another in rapid succession. Theoretically this army should be destroyed by the hydrochloric acid of the gastric juice, practically we know that not to be the case, otherwise no one would ever suffer from typhoid, cholera, &c., and so it arrives in fairly good and close order in the small intestine. The valvulæ conniventes by delaying the flow of foodstuff along the canal aid in its absorption; but what excellent lurking places the recesses of their folds afford the regiments of this hostile army! The single files of columnar epithelial cells lining these trenches, however well trained, are no match in defence against the determined onslaught of clumps of poison-forming bacteria. In the lymphoid tissue of the mucous membrane the situation becomes more critical. The leucocytes make short work of the "laggards" and "camp followers"; they drive the enemy's unassailable "squares" or clumps on to the wire entanglements of the muscularis mucosæ and so break them up, finding in the process fresh opportunities for cutting off detachments.

The close-meshed net of the circular and longitudinal muscle fibres causes a further breaking up, thinning, and spreading out of the bacterial clumps. so also does the supporting tissue of the cœlomic epithelium. The bacteria are thus scattered in small and solitary groups over an extensive area by the time they arrive to give battle to their arch enemy the cells of the visceral peritoneum, trained by the inherited instincts of æons in this particular kind of warfare. Should they survive this, there still remain the serried ranks of leucocytes and the endothelial cells of the omentum, which, to change the metaphor, lies like a huge lazy parasite dining off a constant meal of organisms dutifully brought to it by the vermicular movements of the intestines. For an illustration of this process note the spread of small tubercles in the subserous tissue around a tuberculous ulcer of the intestine. Dr. Hale White says: "It is remarkable that tuberculous peritonitis is so rare in comparison to the frequency with which subperitoneal tubercles are found underneath tuberculous ulcers of the intestine." We know, too, how rare is peritonitis in comparison to the frequency with which we see quite extensive areas of the muscular coat denuded by ulceration of its first and second lines of defence, the mucous membrane. The secret lies in the defensive powers of the visceral endothelium and the omentum.

Of the omentum I may say here that this organ, or more correctly, part of an organ, has not even yet received its due meed of credit for the vitally important function it *constantly* performs on behalf of the mammalian community of cells. It is true that we have advanced since the days when we looked upon it as a mere storehouse for fat or as the abdominal hot-water bottle. We know it absorbs fluid and solid particles, encapsulates necrotic tissue, localises purulent collections, &c.

Mr. Wilkie has shown in some interesting experiments how it will "prevent emigration of bacteria from devitalised bowel." But, as Schieffendecker remarks, "there exists no special organ for pathological processes," and if the omentum depended on occcasional accidents of the above kind to keep it in training its powers would be lost in the course of a generation or two. Its large blood and lymph supply, equal almost to those of the intestines and subject to the same reflex dilatation after meals, its large standing armies of phagocytes, its evolution since the days of its first appearance in the lower vertebrates, convince me that the "emergency" it is called upon to meet is a continuous one, but that its nature is not always equally critical, whilst its source is suggested by the anatomical relationship of omentum and small intestine.

It may be asked why the bacteria, during their passage through the bowel wall, do not enter the portal blood and lymph capillaries, and by these means the general circulation. Now the region in which they are most likely to do so is the mucous tissue, with its rich capillary network and large conspicuous lacteals. Their entrance into the lymph vessel is prevented by the fact that here, unlike any other region of the body, the lymph capillary or lacteal does not begin in an irregular open space, on first view the more expeditious arrangement for the absorption of fat globules, but has a club-shaped end closed in by cells which allow the entry of leucocytes bearing fat globules, but have the power of excluding undesirable passengers. The endothelium of the blood capillary has a similar property of selection and exclusion. But this region is policed by a dense force of leucocytes.

I take it that the immense numbers of phagocytes present on the hypoblastic portion of the gills of fishes are there, not for the purpose of devouring organisms escaping from the blood capillary, but rather of defending the delicate thin-walled vessel, which here forms part of the systemic circulation, from attack and invasion by noxious organisms in the gill stream. In this case virulence of the organism does not matter, for the phagocytes are constantly shedding themselves and their foe into the water current. In the lymphoid tissue of the intestine virulence of the invader does count, and though the leucocytes shrink from engorging the most noxious of them they at least dispute their passage into the lacteal and blood capillary, render any prolonged stay in this region undesirable, and so tend to drive the intruders either back again into the intestine or into the far more fatal trap farther in, the cœlom.

In suppurative diseases of the appendix or peritoneum how very rarely do we find suppuration of the glands draining the affected area; how rarely, indeed, do we find them even enlarged. What a rare disease is pylephlebitis when one considers the opportunities. But in spite of all this micro-organisms do manage to gain entrance into the blood and lymph capillaries. The latter, on account of their size, are more likely to be invaded than the former. They are still liable to be picked out again by the endothelial cells, and any which escape meet their fate, in the latter case in the mesenteric glands, in the former in the liver, where they are arrested by the pseudopodia of the liver cells forming the wall of the portal capillary.

Now we have to consider the methods by which the peritoneal "shambles" are cleared of the bacterial carcasses and their ante-mortem- and endo-toxins without risk to the body tissues. At times of small or normal stress—i.e., when no

"symptoms" are produced—the dead bacteria are either (1) entirely digested by the phagocytes of the omentum; (2) conveyed by them (*a*) back into the intestinal lumen or (*b*) into the mesenteric glands by the lymph channels; (*c*) to the liver by the intestinal and omental blood-vessels, where they are arrested by the liver cells and cast out into the bile. The contaminated lymph of the cavity is absorbed by the visceral endothelium back into the lymph spaces of the intestinal wall and omentum, whence it is either (*a*) extracted by Lieberkühn's glands into the intestine, or (*b*) absorbed by intestinal and omental veins and extracted, perhaps chemically altered, by the liver cells, and excreted in the bile which passes down the intestine and acts possibly as an antitoxin to that particular variety of bacterium.

How often has it happened that a surgeon when operating for a totally different abdominal condition has found miliary tuberculosis of the peritoneum which has given rise to no symptoms. Twice has this experience befallen me—one a case of ventral hernia and the other of inguinal hernia. Both, curiously, were women. They refused my advice to take a prolonged rest in the open air, and three weeks after the operation went back to their housework. Neither has had a day's illness since. Had it not been for the accident of operation this incident in the patients' histories would never have been known, for the normal machinery was equal to the demand.

I would also allude here to the thousands of abdominal cases which in the pre-antiseptic and even the pre-glove days emerged successfully from a surgical operation with suppuration limited to the abdominal wall. The peritoneum had done its work silently and effectively. Lane's constipation bands are not evolution bands, but the scars of silent battles. Not content with this elaborate excretory machinery the portal blood and the blood which has received the outflow of the thoracic duct is conveyed over an immense purifying surface in the alveoli of the lungs before it is considered sufficiently pure to supply the body tissues. Our experience of the expiratory exhalations of certain of our friends proves this to be no superfluous precaution. Now let us take a case in which the stress upon the peritoneal organ was so great that the usual machinery I have just described, unless assisted, is not equal to the task imposed upon it.

Nature is still far from the end of her resources, but from the very fact that the machinery she falls back upon is not constantly in use, symptoms and physical signs are produced. These, so far from impressing us that physiology is "disordered" (Barnard), should serve to demonstrate to us her "extraordinary" methods of reaction to an extraordinary injury.

The symptoms and physical signs of acute miliary tuberculosis which has been caused by the rupture of a small diseased mesenteric gland or of a tuberculous focus in a Fallopian tube will first be considered in detail, with a view to discovering clues to reserve methods of defence relied upon by the peritoneum in times of crisis. To begin with, the invasion is not by permeation, but by a sudden, almost overwhelming flood of bacilli and their toxins. The overdose is thinned and spread out as rapidly as possible beneath the omentum by the quickened vermicular and peristaltic movements of the intestines. These, together with the action of the tubercle toxins upon the exquisitely sensitive parietal peritoneal cells, give rise to anything between vague abdominal discomfort and acute pain, according to the degree of toxicity of the intraperitoneal fluid and the vigour of the contractions. To dilute this toxicity and to aid in killing the bacilli, a large quantity of serum is secreted, and absorption by the visceral endothelium is checked as much as possible, hence there is ascites. But some of the toxin escapes into the general system and causes a rise of temperature, rapid pulse, and respiration. The rapid pulse is turned to good purpose by reflex stimuli from the peritoneum to produce splanchnic arterial hyperæmia. This arterial hyperæmia would result in the hurrying of toxins through the portal vessels into the hepatic veins were it not counteracted by a delayed flow in the portal system. I need not point out all the advantages to be obtained by this "Bier's treatment" on a large scale. It gives the intestine a congested appearance, but it aids greatly the secretion of serum, delays absorption, and gives time for the liver cells to extract those toxins and bacilli which are being conveyed by the portal blood.

All movements of the abdominal wall and the diaphragm would tend to squeeze the septic peritoneal contents into the lymph and blood capillaries, and to hurry their circulation through the portal vein and larger lymph vessels. To minimise this the abdominal wall is made rigid, and the respiratory excursions of the diaphragm lessened in their extent. Peristaltic contraction of the intestinal muscular coat would also tend to have the same effect, so the muscles are inhibited, not paralysed, hence the constipation. I agree with Mr. Peter Daniel when he says that sepsis leads to stasis; we differ, I think, only in our suggestion as to the steps of the process. The delayed circulation in the portal tributaries carries with it the disadvantage that the blood becomes over-venous, so the intestine, *pro tem.*, is converted into a respiratory chamber for the CO_2 and other waste products; hence, there is tympanites. The intestinal epithelium is here only reverting to its ancient function—e.g., in cœlenterates. Were it not for this temporary relief the vitality of the bowel would be very seriously and rapidly interfered with. In these circumstances, it can be imagined that the intestinal route for the excretions of toxins from the peritoneal cavity would not be a very efficient one, so another has to be found. The peritoneum of the stomach now takes on the duty, and the peptic glands do the work normally done by Lieberkühn's glands. The bowel being inhibited, another duct to the exterior must be made use of. The stomach is filled not only with the excretions of its own glands, but also with the increased excretions of the liver cells conveyed to it by the second and first parts of the duodenum. The vomiting centre in the medulla, either reflexly stimulated from the peritoneal cavity or centrally by the poisoned systemic blood, ensures a periodic expulsion of its noxious contents, hence the vomiting of large quantities of fluid. The colour of the vomited matter will depend upon the efforts which the liver cells have to make to meet the difficulties of the case. If the stress is small the hepatic centre in the medulla, which regulates the metabolic activity of the liver cells (the glycogenic centre), whether reflexly or centrally stimulated, goads these cells to a corresponding effort only; the vomit therefore after the expulsion of food will contain light yellow bile and much mucus; under greater stress light green bile, with a more watery acid secretion from the peptic glands, and so on, until in virulent septic cases, such as peritonitis from a perforated gangrenous appendix, we see it gradually change to sage green (acid), to black, and so-called "fæcal" (alkaline towards the end). Also, what is equally important, the combined output of the liver and stomach increases with the urgency of the case, so that the last vomits are invariably copious. In order to provide the necessary fluid for the peritoneal "wash out" the other secretions are reduced, the tongue becomes dry, and the amount of urine decreased. Such, then, are some of the resources of which Nature avails herself in a peritoneal emergency. If the dose is not too large with the aid of this extra help the crisis passes, the leucocytes having in the meantime shut up the bacteria in tubercles. The ascitic fluid is drained away by diarrhœa. The excretory function of the stomach gives place to a purely secretory, so the appetite returns and the tongue cleans, the temperature and pulse become lower, and the balance of health generally is once more restored. An abdominal incision expedites matters considerably.

Now compare this picture which I have drawn of acute tuberculous peritonitis with a more toxic and septic form, due, say, to virulent organisms permeating through the wall of an inwardly directed appendix. So great is their virulence that in their passage they are actually causing necrosis of the tissues of the appendicular wall. The crisis being more urgent, the exertions of the peritoneum become correspondingly strenuous. The pain is usually more severe; the rigidity is more marked; the breathing is shallower but more frequent. The bowel is more congested; in bad cases the flow of the portal blood may be so delayed that the bowel is almost black near the seat of the original poison factory, fading off, the further you get from it, to a purple and dull red. Relief from the CO_2, &c., is more necessary than ever, hence the very marked distension, which in turn should be more pronounced near the poison factory and lessen the further you proceed from it. (This is true in practice, for increasing distension of the intestine, if followed, will lead to the focus of disease, whether that is a seat of obstruction

or inflammation or the exact opposite, the site of a perforation!) The vomiting is incessant and runs more quickly through the gamut of colours from yellow to dark green and brown. Its amount during the 24 hours may seem incredible. Treves mentions a case of one and a half gallons. I saw an even greater amount in a case of pneumococcal peritonitis associated with double pneumonia. To provide the fluid for this peritoneal "wash out" through the liver and stomach the peripheral arteries are constricted, hence the small hard and wiry pulse; the other body secretions are lessened, speech becomes thick, and the dry tongue is rolled about the mouth and between the lips from time to time. The secretion of urine is reduced to a minimum; in severe cases of vomiting it may even be suppressed, the vigorous work of the hepatic and peptic cells rendering any excretion by the renal cells unnecessary. Some of the lymph of the tissues is commandeered for the same service, hence the pinched and drawn appearance of the face and the concentrated condition of the blood. When this supply threatens to fail, or perhaps before, the body fat is broken up into water and carbon dioxide. There is a large supply of this ready at hand in the abdomen, in the subperitoneal and retroperitoneal tissues, the omentum, and the appendices epiploicæ. One pound of fat yields a little more than a pint of water when completely oxidised. In very toxic cases the wasting is very rapid, the fingers and hands look gaunt and thin, the eyes fall back in their sockets. The carbon dioxide accumulates in the blood, giving it the appearance almost of tar, increasing the frequency of the respirations, setting the alæ nasi to work, colouring the lips a livid purple and the countenance an ashen grey.

With the whole body engaged in a death-grapple with a determined enemy, every nerve fibre occupied in transmitting calls from the hard-pressed peritoneum to the other organs for some help in this desperate struggle, with the higher cerebral centres subconsciously aware that the most vital medullary centres, the cardiac, respiratory, vomiting, and hepatic, are working at their highest pressure, it is not to be wondered at that the patient has an "anxious look," is restless and sleepless.

You can abolish most of the above complicated reflex reactions with a good dose of morphia, but *not*—and there's the rub—the stimulus which produced them. To quote Battle and Corner: "Morphia can convert a livid vomiting and distressed patient with rapid pulse and respirations into a very comfortable patient with a slow pulse, slow respirations, moist skin, moving abdominal wall, painless and not necessarily contracted abdomen." To add another from Treves's "Intestinal Obstruction": "The amount of urine if lessened increases; the vomiting becomes less troublesome or ceases for a while; stercoraceous vomiting even may cease and on the reappearance of the symptom the ejected matter may be non-fæculent."

The *raison d'être* of the elaborate network of nerve fibres governing the viscera contained in the peritoneum is not far to seek; the direct connexion of the liver, stomach, and higher reaches of the peritoneum with the medulla suggests that in importance they are on a par with the heart and lungs. Surgeons have long ago learnt that to put this beautifully designed and intricate gear out of action with a dose of morphia is not a wise proceeding in cases where the peritoneal sac is infected, though we still read of the most persevering attempts to control the vomiting with other drugs, happily without any success hitherto.

I have already said that the colour, reaction, and amount of the vomit depend upon the degree of toxicity of the fluid in the peritoneal cavity; they are, therefore, reliable data not only in the diagnosis but still more in the prognosis of pathological conditions within the abdomen.

With the progressive poisoning of the peritoneal cavity causing increased demand upon the excretory powers of the liver and stomach, the latter in turn cause a reflex dilatation of the stomach to receive their combined effusions, thus adding considerably to the discomfort from an already distended abdomen. The gradual filling of the stomach is accompanied by vague epigastric pain, nausea, belching, and great mental depression, and in some cases it was possible to foretell the imminence of a large stinking vomit by the patient's livid face becoming an even duskier due. Haguenot's and Brinton's mechanical theories of the production of fæcal vomiting are open to so many insuperable objections as to make them, in my opinion, no longer tenable.

An infected peritoneum does not always cleanse itself *viâ* the stomach; sometimes the intestinal route is made use of, as in puerperal fever or pneumococcal peritonitis, or they may be used alternately, diarrhœa at one time predominating, at another the vomiting; or, again, as in very virulent infections, both channels may be used to the utmost at the same time, as in Asiatic cholera. I am aware that the accepted view of "the excessive excretion of fluid into the intestine" in this disease is that it "is due to the paralysis of the splanchnic nerves by a toxin formed by the cholera vibrio in the intestine." My suggestion is that the toxin formation takes place in the peritoneum and that the excessive secretions are meant to get rid of it, and the fact that pathologists remark upon the condition of the peritoneum "sticky" (Osler, Wilks, and Moxon), "has a soapy feel" (Cohnheim), lends it some support.

The most frightful instance of post-operative peritoneal sepsis that I ever saw died in four days with choleraic symptoms. I even go so far as to suggest that the symptoms of typhoid fever are due to the infection of the peritoneal cavity by the B. typhosi, the sloughing Peyer's patches being marks of their disputed but victorious passage. Once these barriers were ravaged and passed, I utterly fail to see what could possibly hinder this motile bacillus from entering the peritoneal cavity. A boy's bilious attack is due to peritoneal infection, also the summer diarrhœa of children. Some of the cases of "vicious circle" after gastro-jejunostomy are instances of septic peritonitis. Some of the failures of gastro-jejunostomy are due to the fact that the operation has been performed, not on account of organic pyloric obstruction or gastric or duodenal ulceration, but in cases of chronic infection of the peritoneal cavity, the source of which was not found; the poison therefore continuing, the liver and stomach continued their necessary work of excretion. The abdominal incision and manipulation of the viscera, by temporarily draining the peritoneum and causing a fresh sharp effusion of serum, ensured them a short respite.

The liver and stomach by no means escape themselves scot free in the performance of these vital duties. In cases of acute infection the liver cells, especially those in the outer part of the lobule, on which the greatest stress would fall, show fatty degeneration; in the more chronic forms they die out entirely, and their place is taken by fibrous tissue. Again, the muscular coats of the stomach, constantly bathed in toxic lymph passed into it by the visceral endothelium, would gradually become atonic, causing a chronic dilatation of the organ; sometimes this lymph would actually contain organisms which the peritoneum and omentum had imperfectly dealt with, and these again, during the time that they found themselves in the submucous tissue, would produce necrosis, and begin the mischief of ulceration. In cases of still greater stress upon the peritoneum, as in some cases of puerperal fever, ruptured gangrenous gall-bladder, &c., the organisms set up a general condition of acute phlegmonous gastritis.

The symptoms of "acute intestinal obstruction," as given in the text-books, are not symptoms of obstruction at all. The only symptoms of "obstruction" are paroxysms of acute colicky pain, due to forcible peristalsis, combined with the few reflexes which such a non-toxic stimulus would temporarily produce, and which I need not mention here, except to say that they would be equally characteristic of the passage of a gall-stone, renal calculus, &c. The other symptoms are due, not to the obstruction, but to the supervening poisoning of the peritoneal cavity by organisms now permeating in excessive numbers through bowel wall, the vitality of which had been depressed. Such depression would be produced not only behind a growth or other obstruction, but by interference with its blood-supply, such as embolism of a mesenteric artery, thrombosis of a mesenteric vein, and aneurysms of the abdominal aorta, from injuries to the abdomen, such as blows, run over, &c. Excessive permeation might conceivably take place from the presence of excessive numbers within the bowel, even without any alteration in its wall, and it is not an uncommon experience to have a case die with the symptoms of acute intestinal obstruction where *nothing* can be found post mortem.

My labour will not have been in vain if it causes you to look upon the peritoneum with more questioning eyes. Before venturing to address so learned a society I had fortified myself with a passage from Henle: "It is an important fact that in the whole extent of this matter there is scarcely an opinion which is not founded on experience

and again contradicted by experience. In these circumstances one might advise theory to wait until experience is riper, but I rather think that experience in order to ripen needs the light of a reasonable theory: for Nature only answers when she is asked a question, or more truly she speaks to us constantly and with a thousand tongues, but it is only the answer to our question we hear."

Cheltenham.

THE EXPERIMENTAL TRANSMISSION OF DISSEMINATED SCLEROSIS TO RABBITS.

BY W. E. BULLOCK, M.D. EDIN., B.SC. LOND.,

FORMERLY MCCUNN SCHOLAR AND ASSISTANT TO THE PROFESSOR OF PATHOLOGY, UNIVERSITY OF EDINBURGH; ASSISTANT, IMPERIAL CANCER RESEARCH FUND, LONDON.

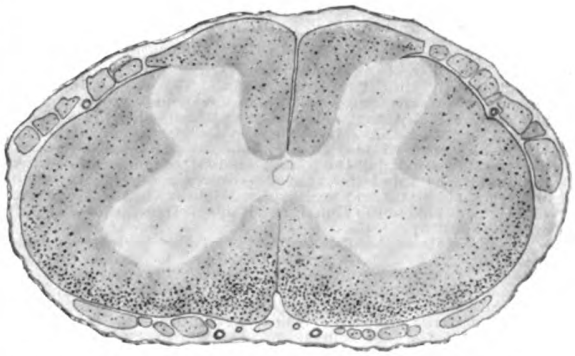
THE naked-eye and microscopic anatomy of the lesions found in multiple sclerosis have been studied with great care by many histologists, and especially by Dr. James Dawson; but so far as I am aware there are no recorded experimental investigations on the etiology of the disease. It is beside the purpose of this short article to analyse the cause of this, though it may be suggested that it is partly due to the more or less general belief that the disease is due to some inherent defect of the nervous system (Strümpel, Ed. Müller). Among many other factors believed to be effective in the causation of the disease one may mention syphilis (Cotala, Perrin-Parisot), the various acute infectious diseases (Marie), chronic poisoning with metals or carbon dioxide (Oppenheim), the puerperium (Balient), and trauma (Mendel). The experiments to be described below afford some evidence that the disease is due either to an infection by an ultramicroscopic organism or to a poison which may be found in the cerebro-spinal fluid.

One of the chief difficulties which beset any experimental investigation into the cause of disseminated sclerosis is the fact that it is impossible to obtain freshly attacked nervous tissue. Owing to the chronicity of the disease one may assume that the amount of virus remaining in the central nervous system at the time of death is exceedingly small. There remains, however, the possibility of withdrawing cerebro-spinal fluid by lumbar puncture during life and inoculating this into animals, as well as the general method of testing the toxicity of the blood, urine, and the Berkefeld filtered water-soluble constituents of the fæces. The first two of these methods were employed in the manner described below.

The cerebro-spinal fluid was obtained from a patient aged 19, a domestic servant, who was under the care of Dr. J. J. Graham Brown in the Royal Infirmary, Edinburgh. At the time the first specimen of the fluid was withdrawn the patient exhibited all the classical signs and symptoms of the disease. She was unable to stand owing to spastic paralysis; her speech was staccato; muscular coördination was defective and nystagmas was marked. She suffered from paralysis of the right external rectus ocular muscle and a right-sided facial paralysis. Optic atrophy was present in both eyes. She complained of cramps and pains in the arms and legs. Increased knee-jerks and Babinski's sign were present.

The fluid obtained was placed in an ice chamber within five minutes of its withdrawal and kept there for 24 hours. Part of it was then injected into a tame rabbit and a cat.

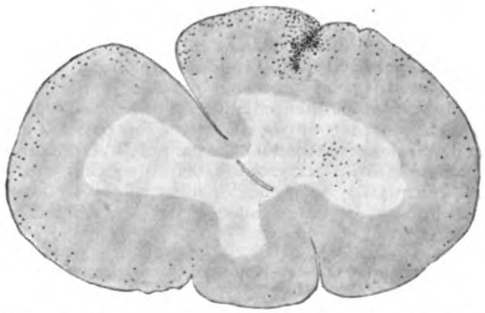
In the case of the rabbit 2 c.c. were injected subcutaneously in the line of the left sciatic nerve, whilst the cat received 2 c.c. intradurally in the thoracic region, the dura being exposed under ether anæsthesia. Tubes of broth, agar, glucose agar, blood agar, and gelatin were inoculated from the remainder of the fluid, which was then replaced in the ice chamber. The culture media showed no growth after 10 days' incubation.



After the injections the animals were isolated from laboratory stock and well tended. Apart from a slight conjunctivitis the cat remained in perfect health for nine weeks, and nothing more need be said concerning the animal.

The rabbit remained in good health for 12 days, but on the thirteenth day developed within 12 hours complete paralysis of the hind limbs. On the fourteenth day the animal was much worse and suffered from incontinence of fæces and urine, the urine containing blood, bladder epithelium, and a variety of micro-organisms. The temperature of the animal was 99° F. On the sixteenth day the animal was completely paralysed in all four limbs, and appeared to be dying. It was therefore killed, and after withdrawing 6 c.c. of sterile heart's blood the whole of its central nervous system, the sciatic nerves, bladder, kidneys, suprarenal bodies, and lungs were removed and preserved in 4 per cent. formalin. There were no signs of inflammation at the site of inoculation.

The sterile heart's blood—proved to be sterile by culture tests—was injected into a young white Andalusian rabbit. The animal remained in good health for eight weeks.



The results of the examination of the organs and tissues of the paralysed rabbit were as follows. The lungs, kidneys, and suprarenal bodies were healthy. The bladder showed a marked cystitis, due probably to an ascending infection. The sciatic nerves were healthy; the spinal cord as a whole was swollen and exhibited in the grey matter of the lumbar and cervical regions naked eye areas of congestion. Frozen sections were made and stained with osmic acid; fragmentation of the myelin sheath in the white matter of the cervical and lumbar regions and in several parts of the dorsal region, together with a swollen appearance of the nerve cells, was observed. Marchi preparations showed no areas of blackened fibres. In sections stained with picro-fuchsin congestion of the membranes was conspicuous.

FIG. 1.

Transverse section of spinal cord of paralysed rabbit, stained by Marchi's method, showing diffuse distribution of degenerated nerve fibres as black dots.

FIG. 2.

Oblique section of spinal cord of the same animal as Fig. 1, stained by Marchi's method, showing a localised area of degeneration.

FIG. 3.

Transverse section of spinal cord of the same animal as in previous figures, stained by Weigert-Pal method, showing very extensive degeneration (pale areas of white matter).

The success which attended this first inoculation of cerebro-spinal fluid led me to use up the fluid which had

stood in the ice-chest for 14 days in inoculation of three more tame rabbits.

The animals employed were: (1) a young white rabbit; (2) a half-grown brown and white animal; and (3) a young black and white animal. Of the first little need be said; on the thirteenth day after inoculation its left hind limb was broken accidentally and the animal had to be killed. The second rabbit remained healthy and active for nine weeks after the inoculation. The third became paralysed in the hind limbs on the twenty-first day; the paralysis was more marked on the left side than on the right and was never so severe as in the first rabbit already described; it did not extend to the fore-limbs, and in seven days had completely disappeared. Three weeks later the animal was reinoculated subcutaneously with fresh cerebro-spinal fluid from the same patient, and up to the present (five weeks afterwards) there has been no sign of paralysis.

A fresh supply of cerebro-spinal fluid from the same case was obtained and divided into two equal portions, one of which was filtered through unglazed porcelain.

The filtered and unfiltered lots—each 1·5 c.c.—were injected subcutaneously into two tame rabbits. The temperature of the animals was taken twice daily and was found to vary between 97° and 101° F.; the animals maintained their weights and general health for 20 days. On the twenty-first day the rabbit which had received the filtered fluid became paralysed, and on the twenty-second day the second animal became paralysed in the left hind limb. This latter animal recovered completely in four days and remained active and healthy for 37 days, when it again became slightly paralysed in the hind limbs. It again rapidly recovered and has remained healthy.

The first animal inoculated with filtered fluid became progressively worse until all four limbs were involved and locomotion became impossible. From this condition the rabbit gradually recovered, until six weeks later it could move with a spastic laborious gait. At this period it was decided to kill the animal with chloroform, and to inject a portion of sterile emulsion of spinal cord into another healthy rabbit, the remainder of the central nervous system being preserved in formalin. The animal into which infected spinal cord emulsion was injected died in seven days, and thus rendered the experiment nugatory.

Histological examination of the remainder of the cord by Weigert-Pal and Marchi methods revealed great areas of degeneration throughout the cord, and especially in the lumbar and cervical enlargements. The brain was practically unaffected. The figures given on the previous page illustrate the type and extent of degeneration commonly found in the region from which the original section was cut.

The toxicity of the blood of the same patient was tested by injecting 5 c.c. into a healthy rabbit. The animal showed no signs of paralysis during the following eight weeks.

At about this time it became possible to obtain cerebro-spinal fluid from another patient who presented the classical signs and symptoms of the disease. This patient, aged 20, also a domestic servant, under the care of Dr. Graham Brown, had suffered about six months before seeking aid in the Royal Infirmary. The cerebro-spinal fluid obtained was divided into two portions, one of which was filtered through the Berkefeld filter.

The filtered and unfiltered lots were now injected subcutaneously into four young wild rabbits which were then separated and carefully looked after. The animals, however, did not thrive; one died in 10 days, a second in 14 days, a third in 21 days, and the fourth in 26 days. None of them showed any signs of paralysis.

A further series of experiments have been conducted, but it is not yet possible to detail the results. The problem of transferring the disease from rabbit to rabbit is being attacked, as well as the many other problems which have arisen during the course of the work.

Summary.—It has been found possible to produce paralysis of the limbs in four rabbits out of five by injecting cerebro-spinal fluid, withdrawn under rigidly aseptic conditions from a case of disseminated sclerosis, subcutaneously into rabbits. The fluid was found to be potent after exposure to a temperature of 0° C. for 14 days, and after being filtered through unglazed porcelain. Histological examination of the spinal cord reveals a complete reproduction of the appearances found in the human subject—viz.: (1) vascular engorgement and fragmentation of the myelin sheath in the early stages; (2) areas of degeneration throughout the cord, demonstrable by the Marchi and Weigert-Pal methods, in the later stages of the disease. Whether the cerebro-spinal fluid obtained from a second case of the disease would have produced paralysis in two wild rabbits or not could not be determined owing to the premature death; in the case of the other two animals the fluid was not potent in producing paralysis. A cat which was inoculated with fluid obtained from the first case remained active and healthy for nine weeks.

Conclusions.—If one assumes that disseminated sclerosis is a definite entity and that the first patient from whom cerebro-spinal fluid was obtained was an instance of the disease one is bound to conclude that the cause of the disease is either a filtrable virus (organism) or a water-soluble poison found in the cerebro-spinal fluid. Whilst the final demonstration of the first conclusion is not yet obtained the balance of probability lies in its favour. Thus the fact that paralysis occurs from 14 to 22 days after inoculation is fairly strong evidence against a non-living poison. Against all this, however, must be placed the possibility that the disease which we call disseminated sclerosis is not individual, but that it may be a symptom-complex which may be produced by two or more causes. The fact that the cerebro-spinal fluid obtained from the second case failed to cause paralysis in four wild rabbits lends some support to this possibility. One must, however, attach some importance to the fact that wild rabbits were used in these experiments, whereas tame ones were employed in the first.

In conclusion, I should like to thank Dr. Graham Brown, P.R.C.P. Edin., for his kindness in placing the material in his wards at my disposal; Professor Lorrain Smith for his interest in the work; and Dr. Alban Andrews for his willing help in procuring aseptic cerebro-spinal fluid.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

FURTHER NOTES ON "POST-ANÆSTHETIC" VOMITING.

BY J. D. MORTIMER, M.B. LOND., F.R.C.S. ENG.,
ANÆSTHETIST, ROYAL WATERLOO HOSPITAL, ST. PETER'S HOSPITAL FOR STONE, ETC.

SINCE the publication of my article on this subject in THE LANCET of June 17th, 1911, I have noted the after-condition, especially with regard to sickness, of 719 patients. As before, short administrations of nitrous oxide or ethyl chloride have been excluded, but otherwise no selection has been made. The results correspond with those of the previous series as regards absent, slight, and moderate vomiting; but there were only a few (8) in whom it was continued or severe, the probable or obvious causes of excess in them being similar to those in the cases described in the previous article. This makes a total of upwards of 1000 cases, in about three-fifths of which (including many long administrations) there was no after-sickness, and it was inconsiderable in the majority of the rest.

After 110 administrations lasting an hour or more, vomiting was absent in 38, slight in 44, moderate or considerable in 28. Amongst these there were only 12 operations not involving viscera, and it was absent (9) or slight (2) in all but one case, showing that time alone is not such an important factor as is usually supposed. It may be said that increased liability to sickness after a long operation on internal organs is due to the greater depth of anæsthesia. Before such operations, however, a preliminary injection of some narcotic is now usually given, and little, if any more anæsthetic is needed than for operations elsewhere. Sickness seems to me to depend much more on the organ involved. Thus, after 45 operations on the kidney vomiting was considerable in half the cases, whereas after 26 hysterectomies (similar as regard time and depth of anæsthesia) it was absent or slight in all but four. Flatulence, nausea, and sometimes hiccough are comparatively common after renal operations. In one case they occurred when the kidney had only been felt *in situ*, not wounded.

I suggest that such after-effects may be to some extent explained by inhibition of the rhythmic action of the diaphragm favouring atonic distension. Dr. William Pasteur has shown that such inhibition is commonly associated with pulmonary disorders following operations in its region.[1]

As regards the value, from this point of view, of previous injection of narcotics—such as morphine and atropine—I think that they only lessen that vomiting which would be associated with spasmodic after-pain or with emotional disturbances, but rather tend to increase it when due to other causes.

These results sustain my previous conclusions that (1) sickness by no means necessarily follows the administration of an anæsthetic, and should not occur to any serious

[1] Oration before the Medical Society of London, THE LANCET, May 20th, 1911, p. 1329.

degree unless there are special conditions (considered in the former article) which influence its effect or independently are responsible for the disaster; (2) that severity of vomiting is not, as usually held, proportionate to a great extent to the mere length of administration; and (3) that when it occurs careful investigation should be made as to its causation, and the treatment directed accordingly.

St. Leonard's-terrace, S.W.

A NOTE ON THE TUBERCULIN REACTION.

BY EDWARD E. PREST, M.A., M.D. CANTAB.,
MEDICAL SUPERINTENDENT OF THE AYRSHIRE SANATORIUM.

AFTER reading with great interest Lydia Rabinowitsch-Kempner's paper on the Nature of Tuberculin, &c., which she read at the meeting of the National Association for the Prevention of Consumption in August last, it occurred to me that some of her experiments on tuberculous guinea-pigs possibly threw considerable light upon some features of one kind of tuberculin reaction, and upon whatever good results may follow upon the injection of tuberculin into febrile patients. She points out that after injections of tuberculin (probably somewhat excessive doses) into tuberculous guinea-pigs tubercle bacilli may be demonstrated in the blood. It might be inferred from this that nothing but harm could follow such a result, but I am by no means certain that such is necessarily the case. These experiments would, however, seem to vindicate Virchow's contention that tuberculin might cause mobilisation of the bacilli.

It is interesting to note that Karl Spengler has stated that the main seats of production and accumulation of immune substances are the red blood cells and not the serum. He has stated that the immune substances in the blood cells are often present in quantities a million times greater than in the corresponding serum. It may, therefore, follow that living bacilli circulating in the blood stream, which under certain conditions become lysed, may accomplish, owing to their intimate mixture with the red blood cells, what toxins acting on ordinary tissues are unable to do, and bring about an end of the disease in some cases and in others produce improvement. I think this probably occurs in those cases where after an injection of tuberculin there is a rapid rise of temperature out of proportion to the increase of physical signs, accompanied by the most profound symptoms of intoxication, sometimes, indeed, producing delirium; after the subsidence of these symptoms, the temperature having rapidly fallen, the patient is very much improved and, indeed, may be practically cured.

A case which bears upon this subject came to my notice recently—that of a patient who had left the Ayrshire Sanatorium over two years since and had been lost sight of, and who at the end of this period came back to see me. He had originally left the sanatorium at the end of three months, being unable to remain for the usual five months. On leaving he was afebrile. He started work, which was of an arduous nature, almost as soon as he had left. During the first day he felt ill, and on the second day he felt very very ill and extremely thirsty. He then asked the foreman if he could keep his job open for a week, and to this the foreman assented. He then went home and found his rectal temperature to be 105° F., and he could do nothing but lie in bed; his appetite had completely gone. He lay in bed from Tuesday until Sunday morning, when his temperature became normal, being as low as 97·7° in the rectum before rising. On the following day he returned to his work and had worked continuously for two years since that time, earning £2 a week. When I saw him the physical signs were compatible with a healed lesion, and he had no cough or sputum.

The injection of tuberculin in febrile cases is obviously not a method to be used indiscriminately; still, it is conceivable that small doses of tuberculin given to febrile cases which have had no tubercle bacilli in their blood might do good. In the above-mentioned case, however, it should be remembered that the temperature was normal before the reaction occurred.

The question also naturally arises as to how much better or worse off this patient would have been had he received a course of tuberculin after having this reaction. I might also add that the case was one tending to fibrosis.

ROYAL SOCIETY OF MEDICINE.

SPECIAL MEETING OF FELLOWS.

Cultural Methods in the Study of Diseases of Unknown Etiology.

ON Monday, Oct. 21st, at a special meeting of Fellows Dr. HIDEYO NOGUCHI gave his postponed demonstration. He said he proposed to take up several questions under the broad title of "The Application of Cultural Methods to the Study of Infectious Diseases of Unknown Etiology." His work on poliomyelitis had been conducted in association with Dr. Flexner. He had cultivated three groups of spirochætæ, the first two of which were pathogenic and the third saprophytic. The first group invaded tissue, the second resided chiefly in the blood, and the third or harmless group lived on the surface of mucous membranes or round about moist lesions. With regard to the cultivation of these spirochætæ, for the first two groups it was necessary to have in the culture medium a piece of fresh sterile animal tissue. This was not necessary in the case of the saprophytic form. For the tissue spirochætæ it was essential to have absolute anaerobiosis, which could be secured by means of an apparatus he had specially constructed. But this anaerobiosis was detrimental to the blood spirochætæ, as a small amount of oxygen was necessary. But for the saprophytic forms complete anaerobiosis was not needed. With regard to the virus of poliomyelitis, it did not matter whether it was visible or not, the mere fact of transmission from one generation to another was proof of the existence of the virus; and the morphological studies could be carried out afterwards. Rabies was known to be infectious in 1870, and the virus was able to pass through a Berkefeld filter. With regard to general paralysis many maintained that this was evidence of a previous syphilitic infection, and some even said it meant active syphilis. It could only be solved by finding the spirochæte in the brain of a general paralytic, and he succeeded in doing that after looking at 70 specimens, finding in this one a solitary specimen of the parasite. He then went over his material again and discovered it in 25 per cent. As all the material in the first search was from one hospital he obtained brains from several other hospitals, and found it in 48 cases out of 200 brains examined. The study of tabes dorsalis along these lines was very difficult and tedious, and he only detected the organism in one posterior column, and soon afterwards a New York colleague found it in another. He then described the luetin or skin test for syphilis, which was as certain as, and much easier to do than, the Wassermann test. He had been able to produce in rabbits lesions similar to those of general paralysis in man by inoculating dead spirochætæ every five days continuously for five months, then resting for five months, then by intracranial or subdural inoculation. He also exhibited some lantern slides which showed that the spirochætæ multiplied by longitudinal fission. Other lantern slides showed in an admirable manner the appearances of artificial cultures of various forms of spirochætæ. Dr. Noguchi also exhibited photographs of syphilitic orchitis in rabbits produced by pure cultures of treponema pallidum, and other slides consisted of photographs of spirochætæ obtained from the brain in a fresh state from a case of general paralysis; some of the parasites were injected into a rabbit and produced syphilitic orchitis, but the incubation period was very long, suggesting that the infection was a mild one. The methods he adopted in producing poliomyelitis were similar to those for causing experimentally relapsing fever. He concluded by demonstrating various stages in the virus of rabies; he did not know whether the change represented sporulation, or segmentation, or degeneration. He referred to Negri's observations and showed lantern slides indicating the form of parasites described by that observer. These bodies had been observed in the brains of dogs suffering from rabies; in rabbits these bodies had not been demonstrated, but he had observed numerous granules. Dr. Noguchi then referred to the "sporulation" forms found in cultures of the virus of rabies, and by means of lantern slides

illustrated the increase in size which these forms underwent in artificial culture media, until finally these bodies broke up into a large number of "granules" similar in appearance to those he had already described.

SURGICAL SECTION.

The Selection of the Incision in Cœliotomy.—Pyelo-radiography.

A MEETING of this section was held on Oct. 14th, Mr. G. H. MAKINS, the President, being in the chair.

Mr. C. A. PANNETT read a paper on the Selection of the Incision in Cœliotomy. He said that in abdominal operations a method of approach should be utilised which would leave the abdominal wall in a functionally intact state. It must be just as perfect a support to, and compressor of, the abdominal contents as previously, and the movements of the trunk must be carried out with the same facility as before. This object could only be attained if (1) no nerves were permanently damaged; and (2) wounds in muscle and aponeurosis were united by firm narrow scars, so situated that they were not subjected to undue cross-tension which would result in their stretching. He had made some observations upon the permanent effects upon the abdominal wall which might remain after the employment of some generally adopted incisions. Incision in the linea alba was so commonly followed by stretching of the scar and separation of the two recti, when the wound had been made below the umbilicus, that the merest reference to the condition need be made. Incision splitting the rectus fibres was commonly followed by paralysis of that part of the rectus which lay medial to the incision. He had seen very extensive paralysis of the rectus when incision in the linea semilunaris had been used for abdominal nephrectomy, or for removing a large peritoneal tumour. Lateral rectus sheath incision was widely employed when dealing with disease of the appendix or with any lesion for which an incision in the linea semilunaris could be adopted. He showed a diagram representing the condition of a patient three months after its employment in an operation for appendicitis. There was paralysis of a portion of the rectus, and the paralysed portion exhibited complete reaction of degeneration. In another case the outer band of the rectus reaching from the scar right down to the pubes was very weak seven months after operation. A diagram made from another case showed a bulging area situated chiefly on the mesial side of the inner extremity of a McBurney's incision. Oblique lumbar incision for exposing the kidney had led in one case to an oval area of paralysed muscle situated above the outer half of Poupart's ligament, some distance in front of the anterior end of the incision. Paralysis of a strip of the rectus below the umbilicus close to the middle line had also followed vertical incision, lateral to the linea semilunaris. He thought that these results depended upon (1) damage to motor nerves coursing through the abdominal wall; or (2) weak union of severed muscular or tendinous fibres; or (3) a combination of these two factors. Hernia in the linea alba was due to insecure union of the divided median tendon. Many of the results illustrated in the diagrams were to be explained by injury done to the motor nerves, and some to combination of injury to nerves and weak union. If the rectus sheath was securely sutured and good union obtained, even although the rectus was paralysed from injury to its nerves, no localised bulging occurred, because the sheath was pulled tightly over the paralysed rectus by the lateral abdominal muscles. Some bulging compared with the opposite side would, however, be seen when the patient coughed, but if the scar stretched bulging would occur. Quite apart from the fact that movements of the trunk were interfered with if the rectus was paralysed, some of the unpleasant after-effects of abdominal operation—namely, dragging pains, constipation, and indigestion—were due, not to adhesions, but to a general diminution of intra-abdominal tension. If one accepted the postulate that injury to nerves should be avoided, it was clear that this condition could only be complied with by making incisions (1) where there were no nerves; (2) parallel to the direction of nerves; or (3) across nerves only where these could be displaced out of the way of possible injury. He thought that an incision through the linea alba should never be employed, at least below the umbilicus. A paramedian incision through both layers of the rectus sheath, the muscle being retracted outwards, had all the advantages without the objections attached to an incision accurately in the middle line. The gall-bladder incision of Mayo Robson and Bevan should never be used. He himself employed for exploration of the gall-bladder region an incision which was a modification of Kocher's. A long paramedian rectus sheath incision was made from about one inch below the ensiform cartilage to the umbilicus, and the abdomen opened in the usual way. If the exposure was inadequate the anterior rectus sheath was separated from the muscle and pulled outwards, and the rectus itself divided part of the way across at a point midway between the ensiform cartilage and the umbilicus. Referring to the relative advantages of the Battle and McBurney incisions for reaching the right iliac region, he said that in 25 consecutive cases of acute appendicitis in which he had used the Battle incision one nerve had to be divided in four cases to gain proper access, whilst in 29 consecutive cases in which the McBurney incision was employed muscle fibres had to be cut across in one case, and there was no doubt that a nerve was injured, judging by the results which followed. It was certain that in these septic cases the McBurney incision healed more quickly than the Battle incision. The oblique incision in the loin recommended for operations upon the colon had certain objections. It was made in a region where the abdominal nerves were crowded together, and as muscle fibres had to be cut across it was not easy to discern and avoid the nerves.

Mr. FRANK KIDD read a paper on Pyelo-radiography. The problem of determining the physiological and pathological state of each kidney before operation had already been solved by means of the catheterising cystoscope and the Roentgen rays. Knowledge of the exact anatomical state of each kidney and ureter before operation was also of vital importance in obtaining perfect surgical results. This could now be obtained by pyelo-radiography, which rendered urinary surgery a more exact science than any other branch of surgery. The fundamental idea had been brought forward by Voelcker and Lichtenberg in 1906 and applied to clinical problems most extensively by Braasch of the Mayo Clinic. It was to pass a ureteric catheter without an anæsthetic, inject a colloid suspension of silver into the renal pelvis, and take a skiagram. The skiagram showed up the outline of the ureter, pelvis, and calyces, and also of the kidney itself. The various solutions employed and methods used for injections were discussed. The method made it possible to detect all the common congenital malformations of the upper urinary tract, such as reduplication of the pelvis and ureters, supernumerary kidneys, the nine possible varieties of "horse-shoe" kidney, solitary kidney, ectopic atrophic, and cystic kidney. Examples of most of these conditions were shown on the screen, the most remarkable of which were: 1. A case of solitary kidney, which had presented itself clinically as a painful abdominal tumour. Pyelo-radiography enabled the diagnosis to be made, and the patient was saved from what must have been a fatal operation. 2. A case of double ureters and double fused kidneys on each side, with a tumour growing from the lower pole of the right kidney. The latter had been removed and the specimen was shown at the meeting. The method also proved useful in the diagnosis of dilatation of the pelvis early and late, either mechanical or inflammatory in origin; in the diagnosis of renal and abdominal tumours; in the diagnosis of obscure abdominal pain; in the diagnosis of stone in the kidney and ureter, and in the diagnosis of renal infections. Little attention had been paid as to what exactly happened when a fluid such as collargol (5–7 per cent.) was injected into the renal pelvis. A large amount of evidence on this point was brought forward. 1. *Pathological.* Specimens removed at operation after the injection of collargol. These were reported on by Dr. Hubert M. Turnbull. 2. *Clinical.* Observations on the states of the urine that followed the collargol injections. 3. *Experimental.* Observations on the effect of injecting collargol into fresh sheep's kidneys at varying pressures maintained for varying times. These experiments were carried out by Mr. E. C. Lindsay. The following conclusions were drawn. The knowledge obtained by pyelo-radiography was of vital importance to the individual patient who wished to make certain of a successful result to his particular operation, and who

could not, therefore, afford to be operated on without it. The solutions so far employed (collargol, cargentos, &c.) did seem to irritate the kidney a little, but the irritation was a passing one, and was recovered from completely in a few days by a process of natural repair. The damage done was far less than that done by an exploratory operation. Those, then, who advised an exploratory operation in preference to carrying out ureteric catheterisation and pyelo-radiography could not criticise the method on the score of possible harm, as their own method caused far more harm and gave far less information. No doubt in the early future a solution would be found which would not irritate the kidney at all. Meantime collargol could be used in weak solutions (5–7 per cent.) under low pressures (30 mm. of Hg) and with as short an exposure as possible (less than 15 seconds). Caution was still necessary in advising pyelo-radiography. It should only be employed by those who were in a position to practise it assiduously in carefully selected cases—that is to say, cases in which otherwise an exploratory operation would seem necessary. The risk was far less than that of an exploratory operation. It was probably not wise to fill up more than one kidney unless the conditions were very exceptional, and that only on one occasion.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

Complete Absence of the Internal Genitalia.—Pyosalpinx of an Accessory Tube.—Adnexal Tuberculosis.—The Serum Diagnosis of Pregnancy.

A MEETING of this section was held on Oct. 9th, Dr. W. S. A. GRIFFITH, the President, being in the chair.

The winter session was opened by the PRESIDENT, who gave the introductory address.

Dr. H. MACNAUGHTON-JONES read a short communication on a case of Complete Absence of the Internal Genitalia. In introducing his remarks on a case in which no internal genitalia could be detected, he said that among other instances he had previously recorded was a case of complete absence of introitus in a child (a small orifice leading to the urethra); a rudimentary vagina and uterus were present, but no adnexa could be detected. He had also had a case in which the external genitalia were normal, the uterus rudimentary, and the adnexa present; and another case similar to the present one. The age of the patient was 27. Her health was good, and an examination was required as the question of marriage arose. As in the other cases, bimanual, vaginal, recto-vaginal, and recto-vesical examinations were made. The external genitalia and vagina were normal; the uterus was represented by a nodule a little larger than a pea, and no vestige of adnexa could be felt. He dwelt on the importance in cases of primary amenorrhœa when menstruation was delayed of not putting off an examination. He had known cases (in one of which the patient had gone to Spa for treatment) where various remedies were used to induce catamenia when the genitalia were absent.—The paper was discussed by Dr. G. F BLACKER and Mr. DOUGLAS DREW, the latter referring to a case in which apparently, so far as pelvic and vaginal examination revealed, no uterus, ovaries, or tubes were present, yet at operation ovaries were found high up in the flanks together with a horse-shoe kidney in the pelvis.

Dr. MACNAUGHTON-JONES also showed a specimen of Pyosalpinx of an Accessory Tube from the Adnexa of a patient, aged 38, unmarried. The Fallopian tube at the right side was converted into an egg-shaped tumour, which contained a quantity of cretaceous matter, the result of an old pyosalpinx. At the left side the adnexa were healthy, but an exactly similar tumour existed at the outer edge of the broad ligament with histological features similar to that of the right side. The specimen was examined by Mr. W. S. Handley, and it was of interest as an instance of a cyst of an accessory Fallopian origin being converted into a pyosalpinx. At either side the cyst was incorporated with the round ligament.

Miss M. H. F. IVENS (Liverpool) read a paper on Adnexal Tuberculosis based on the experience of 23 tabulated cases of which all but one were apparently primary. An early diagnosis followed by operative treatment gave good results. The disease became much more serious when bowel complications had occurred. The history of an attack of obscure peritonitis in girlhood, followed by primary amenorrhœa, was given in four chronic cases, and partial or complete amenorrhœa was very common. Pelvic pain bearing no special relationship to menstruation was generally present, associated with leucorrhœa. Sterility was an almost constant feature; two patients only have borne each one child, many years previously. The majority were in the early "twenties"; 14 were married. In every case a varying degree of thickening of the tubes could be felt. Only two were unilateral. Laparotomy was performed in 22 instances for the removal of the diseased tubes, the uterus being removed only for special indications. Conservative treatment of the ovaries was possible in all but six cases. In one resection of the tube for the removal of a tuberculous nodule was performed. Drainage was avoided except in the presence of a secondary infection, and primary union usually occurred. Two cases died, one from post-operative hæmatemesis and one from septic nephritis. Sixteen were traced and did well. Three made a good immediate recovery, but were then lost sight of. One required a second operation for the removal of the remaining tube. The one case in which the disease was secondary died a year after operation. Two cases came under observation with acute abdominal symptoms due to the rapid enlargement of pre-existing chronic cysts, where the disease had apparently undergone a spontaneous cure. Miss Ivens therefore advocated the operative treatment of all cases of adnexal tuberculosis, except in the presence of a second active focus, and considered that the removal of tuberculous products not only had a very beneficial effect on the general health, but at the same time obviated the risks of later dissemination or local complications.—Professor H. BRIGGS (Liverpool), who alluded to the chronic character of Miss Ivens's cases, said that in more acute cases, which had some clinical resemblance to typhoid fever, operation seemed imperative. In the majority of cases there were tuberculous foci elsewhere, and their aggravation or relief by operation could not be locally governed.—Mr. DREW said that he had considerable experience in the question of operation for tuberculous peritonitis in children, but had not met with a case in which there was disease of the tubes. Possibly in Miss Ivens's cases tuberculous peritonitis was an antecedent factor. Mr. Drew asked in what percentage of cases a tuberculous endometritis was present. Possibly it was of frequent occurrence, but appeared to recover spontaneously after the main lesion was removed.—Dr. MACNAUGHTON-JONES remarked that a few years back he had read a paper before the section on Primary Tuberculosis of the Fallopian Tube, and had shown three specimens, and he referred to another paper that had appeared in the *Edinburgh Medical Journal*, in which statistics were collected of many thousand cases of genital tuberculosis. In these 8 to 9 per cent. were primary. In young persons, seeing the difficulty of diagnosis, every test for the presence of tubercle should be made. In Miss Ivens's cases the greater number were under 30, but 40 per cent. remained well some considerable time after operation.—In reply, Miss IVENS stated that her cases included types of both active and chronic disease. Tuberculous endometritis had been found once, but systematic curettage had not been practised, as leucorrhœa tended to disappear after removal of the diseased tubes. It was possible that in cases where tuberculous peritonitis had occurred in childhood the infection remained latent to become active with the onset of puberty.

Dr. R. L. MACKENZIE WALLIS and Dr. HERBERT WILLIAMSON contributed a paper on the Serum Diagnosis of Pregnancy, with a demonstration of apparatus and methods. The paper was read in two parts, Dr. Wallis taking the experimental chemical department and Dr. Williamson the clinical aspects. In Part I. Dr. Wallis dealt with the two methods devised by Abderhalden for the diagnosis of pregnancy—namely, the optical test and the dialysation method. The principle upon which these two tests is based is the reaction of the blood to foreign substances introduced from without. Any foreign body when injected into the circulation excites the production of a protective or guardian ferment, which rapidly destroys the substance. The proteins contained in placental tissue thus produce a specific ferment, and this can be detected in the blood serum of pregnant women by both methods from the seventh week and up to 15 days after labour. The tests depend, therefore, upon the presence of chorionic villi in the body, which are capable of being washed into the circulation and producing the

special ferment necessary for their disintegration. That such a ferment is mobilised in the blood has been conclusively shown by experiments on animals. For the optical test a good polarimeter was required, and also a preparation of placental peptone, the details of the isolation of this material being given. The splitting of this placental peptone into amino-acids by the ferment in the blood serum could then be followed by the optical changes that ensue. The technique employed by Dr. Wallis in the dialysation test was given in detail, including the preparation of the placental tissue, the testing of the dialysing tubes, and the collection of the serum. The necessity of absolute asepsis throughout was specially emphasised. The application of the ninhydrin reaction for the detection of dialysable substances was described, and attention drawn to the sources of possible errors. Judging from the results obtained with over 100 cases, the writer had no hesitation in stating that the test was of value in the diagnosis particularly of the following conditions: (1) the diagnosis of early pregnancy; (2) the differentiation of fibroids from pregnancy; (3) the diagnosis of chorion-epithelioma; (4) the presence of a retained placenta; and (5) the diagnosis of an ectopic pregnancy, where the latter has not been followed by tubal abortion and hæmatocele. In Part II. of the paper Dr. Williamson pointed out the importance of Abderhalden's work, remarking that if it be true that the blood of a pregnant or recently delivered woman contains a ferment specific to placental albumin, if this ferment be constantly present and can be easily demonstrated, if the sources of error are few and can be readily avoided, then the test possesses great value in both clinical and forensic medicine. He reported a series of 50 controls made by Dr. Wallis. Of these, 20 women were either in the last three months of pregnancy or had been recently delivered. In every case the result was positive. Thirty women were not pregnant, and in all these patients the reaction was negative. He then proceeded to give clinical details of 16 cases in which the test had been applied for diagnostic purposes. The patients had all been kept under observation and the results were: Correct deduction drawn from the test, 12; incorrect, 2; result still in doubt, 2. The cases were as follows: Suspected ectopic gestation, 3; pelvic and abdominal tumours where it was suspected that the whole or part of the tumour might be the pregnant uterus, 5; suspected chorion-epithelioma, 2; chorea in a woman of 21. 1; heart disease with amenorrhœa, 1; nephritis with exacerbation of symptoms and amenorrhœa, 2; late puerperal sepsis, 2; total, 16. The two patients who gave a positive reaction in the absence of pregnancy both suffered from pyosalpinx, and this suggested the advisability of ascertaining whether a similar result was common in suppurating cases. The controls made did not support this view. Dr. Williamson insisted upon the importance of subjecting at regular intervals to Abderhalden's test all patients who have borne a hydatidform mole, for should a chorion-epithelioma develop the test remains positive instead of becoming negative in a few days as after a normal pregnancy. This fact was well illustrated by the case (which he quoted in detail) of a woman who developed the symptoms of chorion-epithelioma 15 months after the expulsion of a mole. From his experience he drew the following deductions: (1) It is established that the serum of pregnant women contains a ferment specific to placental albumin; (2) that this ferment can be demonstrated from the eighth week of pregnancy until 10 days after delivery; (3) that it may be demonstrated both by the polarimeter and by the methods of dialysis; (4) that the former method is more reliable, in that the sources of error are fewer; (5) that the accuracy of the test depends upon the most scrupulous care in detail, and it is only in the hands of an expert that the results can be relied upon; (6) that the ferment is found only when chorionic tissue is present in the body; (7) it is probable that under certain conditions not fully understood at present, the colour reactions and optical effects produced by the ferment may be simulated; and (8) that the common sources of error have already been detected, and that in the near future the test may be expected to give reliable results.—The two papers were discussed by the PRESIDENT, Dr. ARCHIBALD E. GARROD, Dr. BLACKER, Dr. D. EMBLETON, Dr. A. LEITCH, Dr. M. DONALDSON, and Dr. A. W. BOURNE.—Dr. WALLIS and Dr. WILLIAMSON replied.

SECTION OF OTOLOGY.

Exhibition of Cases.

A MEETING of this section was held on Oct. 17th, Mr. RICHARD LAKE, the President, being in the chair.

Mr. W. M. MOLLISON showed a case of Severe Injury to the Left Ear and Eye, which was of interest as promising further light on the pathology of eye fixation or the physiology of caloric nystagmus. While at sea three months ago the patient, a man aged 43, received a severe blow on the left side of the head, which it was feared would prove fatal, hence but little treatment was adopted. But he recovered generally, though with loss of sight and hearing on the left side. On admission to hospital the third to the seventh cranial nerves appeared to be functionless on the injured side. In the sound ear the upper tone limit was 20,000 vibrations, in the left 12,000. Ten turns in the rotation test showed 50 seconds nystagmus on the right side, 10 seconds on the left. An operation three weeks ago to restore the left meatus improved the left upper tone limit to 18,000. The damaged eye showed the rotatory movements very effectively. This eye would be removed in a few days.—Mr. G. J. JENKINS and Mr. W. STUART-LOW discussed the case, and it was decided to carry out a further series of tests before removal of the eye.

Mr. SYDNEY R. SCOTT showed a case of Sero-purulent Lepto-meningitis in which there was rapid recovery after he performed the translabyrinthine operation. The diagnosis was made on the presence of 3500 polymorphonuclear leucocytes per c.mm. in the cerebro-spinal fluid which was withdrawn by lumbar puncture. The meningitis arose in connexion with labyrinth disease, secondary to chronic suppurative otitis media.—The PRESIDENT asked whether the gravity of the case was enhanced by the employment of skin-grafting.—Mr. C. E. WEST said he had discontinued skin-grafting in cases where he could not find a fistula at the time of the operation, as he had had two unfortunate experiences.—Mr. J. F. O'MALLEY discussed what symptoms and signs should be held to indicate that vestibulotomy should be performed; also what were the risks from that operation. Bárány did not open the labyrinth in cases of circumscribed labyrinthitis with moderate hearing, unless the patient had severe vertigo and vomiting. Neumann regarded a case as inflammatory when the hearing was good, even when the tests showed no response from the vestibular apparatus, and he preferred to watch it rather than operate, and Mr. O'Malley's own practice was founded on that of those observers. In Mr. Scott's case the hearing was relatively good, and the patient was not acutely ill. The great risk in vestibulotomy was meningitis, and such cases should not be skin-grafted without serious consideration. The more efficient the graft the more completely would it imprison any pus which might be present.—Dr. DAN MCKENZIE supported Mr. O'Malley's remarks. Unless the labyrinth was obviously destroyed as a whole he was content to do merely the radical mastoid operation. Several members had shown cases in which fistulæ had healed and the labyrinthine irritation had passed off after the simple radical mastoid operation.—Mr. SCOTT, in reply, said he did not show the case because he had skin-grafted it, but to illustrate the method of early diagnosis.

Among other cases shown was one by Mr. HUNTER F. TOD of Trichophyton Granuloma, affecting the auricle and other parts of the body. There had been great benefit from the application of X rays.

DERMATOLOGICAL SECTION.

Exhibition of Cases and Specimens.

A MEETING of this section was held on Oct. 16th, Dr. J. J. PRINGLE, the President, being in the chair.—After some preliminary remarks by the PRESIDENT Dr. S. E. DORE showed a case of Granuloma Annulare of the hands in a man for many years resident in Ceylon, who also presented the condition known as "tropical skin."—Dr. A. M. H. GRAY and Dr. G. PERNET had observed good results from the treatment of the former condition by X rays.

Dr. GRAHAM LITTLE showed a case of Raynaud's Disease in a middle-aged woman with marked nail changes of the hands and feet.—The PRESIDENT, Dr. H. G. ADAMSON, and Dr. PARKES WEBER suggested the possibility of a ringworm invasion.

Dr. LITTLE also showed a case of unusually acute Acne Varioliformis of the Scalp and Face.—The PRESIDENT remarked on the rarity and difficulty of diagnosis in such acute cases in the early stages, and referred to the successful results reported from America by vaccine treatment, which his own experience had not enabled him to confirm.

Dr. LITTLE also showed a case of Chronic Hypertrophy of Both Lips, probably secondary to pyorrhœa alveolaris.

Dr. J. H. SEQUEIRA brought forward an example of Mixed Leprosy.—Dr. A. WHITFIELD referred to the use of salvarsan and tuberculin for diagnostic purposes in such cases, and Dr. PERNET related a case in which tuberculin had provoked an eruption of leprous nodules.—In reply Dr. SEQUEIRA stated that in his experience the Wassermann reaction was not constant in leprosy.

Dr. SEQUEIRA also showed a typical case of so-called Multiple Idiopathic Pigmented Sarcoma in an early stage in a Russian Jew.—The PRESIDENT referred to two cases of this disease under his care, in one of which spontaneous involution occurred; and expressed the opinion that pathologically the disease presented affinities with granuloma fungoides.—Dr. MACLEOD reported having found lymphomatous nodules in sections from one case.—In reply to the PRESIDENT, Dr. SEQUEIRA stated that there were evidences of gout in two out of the five cases which he had observed.

Dr. PERNET exhibited: (1) A case of Diffuse Vascular Nævus in a boy; (2) a case of Patchy Alopecia with Secondary Syphilis; and (3) a Permanent Alopecia following X ray treatment for tinea tonsurans with dystrophy of the nails.

Dr. W. K. SIBLEY showed a case of very extensive mixed Nævus implicating buccal and nasal mucous membranes.—The PRESIDENT, Dr. J. H. STOWERS, and Dr. SEQUEIRA discussed the case.

Dr. J. H. M. MACLEOD showed a case of Vesicating Urticaria affecting the face, arms, and hands in a girl aged 12, to elicit opinions as to diagnosis and nomenclature. He discussed its relationship with erythema multiforme, dermatitis herpetiformis, and hydroa vacciniforme.—The PRESIDENT said that he was familiar with such cases, especially in private practice, and experienced the same difficulty as the exhibitor in classifying them; he agreed with Dr. MacLeod that the best method of treatment was by intestinal antisepsis.—Dr. PERNET and Dr. A. EDDOWES made remarks on the case.

Dr. HALDIN DAVIS brought forward a case of Mycosis Fungoides in a woman exhibited some months previously. It had undergone marked improvement in many respects under arsenical treatment, no local remedy except soft paraffin having been used.—The PRESIDENT, Dr. PERNET, Dr. SEQUEIRA, and Dr. ADAMSON spoke on the case, which was one of much interest.

Dr. J. L. BUNCH showed: (1) A child with Keratosis Spinulosus of the Scalp; and (2) a man suffering from typical and extensive Xantho-Erythrodermia Perstans.

Dr. DORE showed for Dr. A. WINKELRIED WILLIAMS a case of Linear Atrophy of the Arms and Legs.

LIVERPOOL MEDICAL INSTITUTION.—The first ordinary meeting of this society was held on Oct. 16th, Mr. Robert Jones, the President, being in the chair.—The President read an inaugural address on the views held by the late Mr. H. O. Thomas, more especially on Intestinal Obstruction. The works of the late Mr. Thomas, with the exception of his splints, were too little known, partly owing to his writings having been published privately. Mr. Thomas, writing in 1884, recognised the futility of the commonly advocated methods of treating intestinal obstruction—namely, by purgation, enemata, and milk diet. He recognised that where a mechanical condition was the obstruction no medical treatment could avail anything, but that in cases of functional obstruction it was possible by resting the bowel, by rendering the contents above the block fluid and non-irritating, and by relieving pain, to give a favourable termination to many cases. The treatment he advised was first to relieve pain by hypodermic injections of morphia, to allay thirst by the administration of water, and to withhold all food that would add to the contents of the intestine. Cases so treated might go on for from 40 to 50 days. Resolution occurred by the patient passing first flatus, perhaps some small scybala, then a large pultaceous motion followed by watery evacuations. Mr. Thomas was particularly anxious about his cases at this stage, enforcing complete rest and allowing food to be given only very gradually and of such a kind as to produce as little intestinal residue as possible. The President alluded to the views of Ochsener, of Chicago, who had recommended lavage and starvation while he withheld cathartics.—Mr. Rushton Parker proposed a vote of thanks to the President, which was seconded by Mr. F. T. Paul.

UNITED SERVICES MEDICAL SOCIETY.—The opening meeting of the session 1913–14 was held at the Royal Army Medical College on Oct. 9th, Colonel Bruce M. Skinner, M.V.O., the President, being in the chair.—The President delivered the inaugural address, which dealt with the objects and uses of the society (*vide* THE LANCET, Oct. 11th, p. 1056).—Lieutenant-Colonel E. M. Wilson, C.B., C.M.G., D.S.O., R.A.M.C., read a paper on Some Problems of Mobilisation specially affecting the Royal Army Medical Corps. In the course of a most interesting paper, which, however, does not lend itself well to summary, special stress was laid on the following points. 1. The first great problem in the mobilisation of medical units is the fact that these units are only formed on mobilisation. In most other units something exists in peace which can be used as a nucleus on which to commence, but in the Royal Army Medical Corps not only have we no nucleus, but it is necessary practically to destroy the whole existing peace organisation, so far as the subordinate *personnel* is concerned, in order to create the new units required for the uses of war. It is hardly sufficiently realised what an absolutely clean sweep there will be of all effectives from our hospitals when mobilisation is ordered. 2. The second great fact that must be faced is the extreme rapidity with which mobilisation will be effected. In 1899 the military hospitals were gradually stripped of their trained non-commission officers and men, but next time the denudation will be complete and immediate. This will lead to great difficulty until the home hospital reserve men of the St. John Ambulance Brigade have become accustomed to their duties. 3. A third difficulty is the great variety of duties exacted from our corps owing to the diverse nature of our active service units. This all means more complicated training and more need for specialisation. 4. The proportion of specially trained soldiers required for army medical purposes is much larger than in any other military units except perhaps the Royal Engineers and the Army Service Corps. In a general hospital there are 56 specially trained men out of a total subordinate *personnel* of 143, or 40 per cent. It will be evident that it is more difficult to create and maintain a unit of this description than one of simpler formation, though much larger in total numbers. 5. Since the *personnel* of our units is composed of three classes of men, fully trained serving soldiers, regular reservists that have been fully trained, and partially trained special reservists, it is not easy to determine what is the best proportion of each class nor how to maintain that proportion when decided. 6. Another difficulty is how best to allot the duties laid down for various officers on mobilisation to suit the special requirements of the Royal Army Medical Corps. 7. Finally, there is the question of numbers. Our Peace establishment serving at home is 3065, and we shall require 8781 non-commission officers and men to complete our War establishments on mobilisation. As the balance will have to be made up from reservists, who are in most cases privates, there will be an immense and immediate demand for non-commissioned officers. Lieutenant-Colonel Wilson made the following suggestions. 1. The duty imposed on all officers continuously and incessantly to train all the men possible in some special line of work. Dispensers, nurses, and clerks can be trained at all stations, and cooks at several centres, but the chief difficulty will be with mental attendants, packers and storemen, mercurial rubbers, &c. 2. To provide for the large requirements of non-commission officers every intelligent and well-conducted man should be encouraged to qualify at any rate for the rank of corporal. 3. Non-commission officers detailed for special positions in units should be practised in those duties in peace, and special attention might be given to returns relating to allotments of pay and separation allowances, &c., as the correct rendering of these returns would not only spare the Pay Department much trouble, but also prevent hardship and

suffering to the families and relatives of soldiers. It would be a good plan if in each unit one or two non-commission officers were kept constantly efficient in these returns and the regulations connected with them. 4. With regard to the allocation of duties of the officer commanding a regimental depôt or company, the officer commanding a unit, and the officer commanding details, it seems probable that the officer commanding a company of the Royal Army Medical Corps, the Assistant Director of Medical Services of a district, in fact, should be prepared, generally speaking, to undertake them all. 5. Officers of the Territorial Force should exert their influence to persuade their men to join category B. It seems a great pity that Territorial non-commissioned officers have to revert to the rank of private on mobilising in this category, but this ought not to prove a deterrent, as it is certain that in the great demand which is sure to exist for non-commissioned officers these men will be promoted again at once. 6. A proportion of non-commissioned officers should be allowed for category A of the Special Reserve. 7. Finally, it is to be recommended, not only for the Royal Army Medical Corps, but for all troops on mobilisation, that one of the two medical examinations at present laid down should be abandoned. The double system would probably lead to inefficient examination, medical officers relying on the previous or subsequent examination to settle doubtful cases, and when the enormous nature of the work is considered the difficulty is in no way diminished by requiring it to be repeated twice over.—Surgeon-General Sir W. Launcelot Gubbins, K.C.B., Director-General, Army Medical Service, Colonel J. Harper, A.M.S. (T.F.), and the President took part in the discussion.

Reviews and Notices of Books.

The Nervous and Chemical Regulators of Metabolism. Lectures by D. NOËL PATON, M.D., B.Sc., Professor of Physiology in the University of Glasgow. London: Macmillan and Co., Limited. 1913. Pp. 217. Price 6*s.* net.

IT appears that the substance of Dr. Paton's account of the Regulators of Metabolism was originally presented in the form of lectures, illustrated by lantern slides and by experimental demonstrations. The lecture form has not been preserved, but instead a subdivision according to subjects has been adopted, and "this is so clearly indicated by the use of head-lines and of heavy type in the text that an index has been considered superfluous." The author expresses his indebtedness to Biedl's "Innere Sekretion," a review of which appeared in THE LANCET of March 22nd, 1913.

The author takes up the position that "we now regard not only functional activity, but also structure, as a result of the chemical changes in protoplasm." Coördination of metabolism of all the different tissues and organs is necessary, and it is the purpose of these "Lectures" to consider the various factors which bring about this coördination and regulation. Three factors are chiefly concerned: (1) the nervous system; (2) the chemical products of various organs, the so-called internal secretions; and (3) what the author calls "hereditary inertia or inherited developmental tendencies." The last factor is dominant in embryonic life, while the first two become more fully prominent as development advances, and in the fully formed higher vertebrates they entirely displace the last. A short account in two sections—occupying about 30 pages—is given of "hereditary inertia" and regulation by the nervous system. The remainder of the work is practically devoted to the chemical regulators—internal secretions derived from ductless glands—a misleading title. The author prefers the term endocrinous glands. The sources of these internal secretions are classified according to their seat of origin into the following groups: From the nervous system, chromaffin tissue, hypophysis cerebri; buccal cavity, thyroid and pituitary; intestine, pancreas and mucosa of small intestine; branchial arches, parathyroid and thymus; mesothelium of the genital ridge, gonads and inter-renal bodies. The structure and physiology of each are then considered systematically.

Less than 30 pages are devoted to the consideration of chromaffin tissue, and, of course, considerable attention is given to adrenalin. The author discusses the various possible ways in which it acts. About six pages are assigned to the hypophysis, while reference is made to the action of hypophysin in the flow of milk, as noted by Schäfer and McKenzie. We failed to note any reference to the observation by Ott, which was made prior to the observation of Schäfer. About 16 pages suffice for the thyroid and about nine for the pituitary. The summary is concise and suggestive, but the author cannot stop "to consider the cause of endemic cretinism or the interesting experiments which have been made on animals to induce it by drinking the water of these goitrous districts"—i.e., the goitrous Alpine districts.

The pancreas and intestinal (small) mucosa together occupy nine pages. The pancreas is described as a "compound racemose gland." In most text-books the term "tubular" is used, not racemose. As to the islets of Langerhans, the author expresses the opinion that probably two kinds exist—the true and the false; the latter may be produced by changes in the acinal tissue as was first described by Dale. To the consideration of the thymus about 18 pages are given, and the relation of this gland to the gonads is proved to be of a very definite character, but the author has been unable to detect any reciprocal relation between thymus and ovaries. The thymus, like the gonads, in the male at least, exercises an influence on the rate of growth. The parathyroids are discussed in 18 pages. We take it that "von Eiselberg" is a misprint for A. von Eiselsberg.

To the gonads, or sex glands, about 40 pages are given, and the conclusion is arrived at that male and female gonads yield an internal secretion which acts upon the metabolism of the body to stimulate it in each sex in a specific manner, and that almost certainly this internal secretion is a product of the interstitial cells. These interstitial cells may be regarded as a middleman between the soma and gametes, and it is through them that the soma and gametes influence one another. A few pages devoted to inter-renal tissue bring the reader to Section IV., which deals with the interrelations of the endocrinous glands. This section is illustrated by a series of charts to show graphically the probable relationships. A short section is taken up with the relation of endocrinous structures and the nervous system. Evolution of endocrinous glands is discussed in five pages. The bibliography extends to five pages. The "Lectures" are dedicated to Mr. J. Francis Mason, M.P., "in recognition of generous help given to research."

The author has given an excellent, concise, and readable exposition of a fascinating subject, a subject which has been in part illuminated by his own researches and those of his pupils; and we have reason to believe that the proofs were passed for press in June last, long before the discussion that took place on this subject at the International Medical Congress in London. We think that the author is justified in choosing as his motto on the dedication page, "Ex tenebris lux."

The Principles and Practice of Medical Hydrology: being the Science of Treatment by Waters and Baths. By R. FORTESCUE FOX, M.D. Lond. University of London Press: Hodder and Stoughton and Henry Frowde. 1913. Pp. 295. Price 6*s.* net.

Dr. Fox's definition of his main title is as follows: "Medical hydrology is the science of waters, vapours, and mineral or organic deposits in connexion with waters as used in medicine, both by internal administration and in the form of baths and applications." Taken in all its manifestations

this is a large subject, and the author deserves credit for having been able to deal with it as fully as he has done in a work of no great compass.

The book is divided into four parts: I. The Physiology of Bathing; II. Hydrotherapy; III. Mineral Springs and Baths; IV. Indications for Hydrological Treatment, this last section including chapters on the geographical distribution of mineral waters and an index of spas. Section II. commences with a historical *résumé* of modern hydrotherapeutics, the pioneer of which in this country was Sir John Floyer, a physician of Lichfield, who published works on baths in 1697 and 1722. The medicinal use of baths and waters is at least as old as Hippocrates, who gives instruction for the use of the bath in disease in his treatise *De Regimine Acutorum*, and one medicinal use of the bath—namely, the removal of fatigue—is as old as Homer—e.g., *Iliad* XXII., 442, et seq. But, as Dr. Fox shows, it is only within the last 40 years or so that "a whole new science of hydrotherapy has been built up on a clinical and experimental basis." He concludes this chapter with a plea for the instalment of "medical baths," —i.e., of institutions where ordinary water, hot or cold, can be used for medicinal purposes under skilled professional control, and he contrasts the usage of foreign countries with that of our own, greatly to the disadvantage of the latter. The remainder of this section is devoted to an account of the various methods of hydrotherapy, where water is used as a vehicle of energy, and not on account of any chemical qualities which it may possess.

Dr. Fox's book will be found very useful by the ordinary practitioner who may not have access to that work which he calls "Sir Hermann and Dr. Parkes Weber's monumental work on Balneotherapy and Climatotherapy." It is pertinent here to refer to a letter by Dr Fox in the *Times* of Sept. 6th, wherein he pointed out that in France, Germany, Austria-Hungary, Italy, Switzerland, Holland, Belgium, and Sweden in Europe, and also in America, there are either chairs of hydrology or lectures given thereon at various universities, while there are practically none in England. This lacuna, he suggests, should be filled by the University of London founding a chair in medical hydrology, through which facilities could be given to medical men throughout the Empire for studying the subject. Should such a chair be founded, Dr. Fox's book will form an admirable introduction to the lectures delivered therefrom.

Manual of Bacteriology. By ROBERT MUIR, M.A., M.D. Edin., F.R.C.P. Edin., Professor of Pathology, University of Glasgow; and JAMES RITCHIE, M.A., M.D. Edin., F.R.C.P. Edin., Professor of Bacteriology, University of Edinburgh. Sixth edition. With 192 illustrations in the text and six coloured plates. London: Henry Frowde and Hodder and Stoughton. 1913. Pp. 736. Price 10*s.* 6*d.* net.

NOTWITHSTANDING the large number of English and American text-books that have appeared on bacteriology this work still maintains its position as that which, on the whole, is best suited to the needs of the medical student and practitioner. The feat of revision and the incorporation of new material without excessive enlargement of the work has once more been accomplished. The growing importance of the pathogenic fungi has necessitated the introduction of a new chapter dealing with these organisms. This accounts for the greater part of the increase in size and for the increased number of illustrations. The next most important addition is a section on the bacteriology of milk. The whole book has undergone that very difficult form of revision which consists in altering the point of view from which the old facts are regarded so as to bring them into proper relation with new facts and the most recent opinions. Thus, in the chapter on tuberculosis the section on tuberculins and their effects has been considerably modified, and in the allied subject of leprosy recent work on the attempted culture of the B. lepræ is incorporated, while the paragraphs on the pathology of anthrax have been revised. Turning to the B. typhosus and its allies much recent work finds summary recognition in slight changes of nomenclature, in the separate treatment of B. suipestifer, in the statements as to the varying frequency of B. paratyphosus A and B in different countries, and in the paragraph on mutation. Anaphylaxis is a subject not yet capable of absolute treatment, but the essential facts and the best authenticated theories are given with a leaning apparently towards the views of Friedberger.

The printing, paper, and general appearance of this edition are satisfactory, and the excellent illustrations are well reproduced. This sixth edition worthily upholds the standard of its predecessors.

How to Diagnose Small-pox: A Guide for General Practitioners, Post-graduate Students, and Others. By W. McC. WANKLYN, B.A. Cantab., M.R.C.S. Eng., L.R.C.P. Lond., D.P.H. With illustrations London: Smith, Elder, and Co. 1913. Pp. 104. Price 3*s.* 6*d.* net.

SMALL-POX has been said to be the disease in which, more than in any other, it is possible to arrive at a certain diagnosis, and a "doubtful case" is practically unknown in a small-pox hospital. Here, however, the medical officer has experience of the disease and is able to follow his cases in their clinical course, while he also has the result of vaccination to aid him in the diagnosis of those few which remain uncertain. But it is otherwise with the general practitioner or the medical officer of health, whose diagnosis has to be made, probably, as a result of a single examination and at a period when the evidence may be much less definite than it will shortly become. Fortunately, even in these circumstances the disease is usually so definite that failure to suspect it is not very common. But it is sometimes overlooked, with serious consequences, while it is also not uncommon in the time of small-pox epidemics for other diseases to be diagnosed as variola on quite inadequate grounds.

Dr. Wanklyn's monograph is directed solely to the identification of small-pox; he leaves to the text-books the description of the course of the disease, and limits himself to a discussion of the questions to be answered when small-pox is suspected, and of the essential points which it is important to remember if the possibility of small-pox is not to be overlooked. We think that no one who has had any considerable experience of small-pox in this country will find himself in serious disagreement with any part of Dr. Wanklyn's exposition, which is based on exceptional personal experience gained in the preliminary sorting of London cases of small-pox sent to the hospitals of the Metropolitan Asylums Board. Among the points on which he lays special stress are the necessity of examination of the whole surface of the body and the distribution of the rash. The latter is illustrated by a useful series of diagrams, and the importance of looking for abundance of rash on parts which are subject to irritation is duly insisted upon. A well-marked rash cannot, he considers, be due to small-pox if the skin of a whole limb or other extensive area is entirely free from the rash. The "umbilication" of small-pox vesicles has long ceased to be regarded as pathognomonic, and Dr. Wanklyn emphasises the danger of relying upon this feature of distinction between variola and varicella. Recent and successful vaccination, he observes,

completely excludes small-pox, but he does not consider that the vaccinal condition is of great assistance to diagnosis in ordinary cases. This is, no doubt, correct when regard is had to the stage at which diagnosis has to be made. Well-vaccinated cases not infrequently show copious and typical rashes at the onset of their attack, although the effect of their vaccination on the subsequent stages of the pocks may be marked. The diagnosis of the initial rashes and their special characters are also fully discussed.

Dr. Wanklyn's explanations are clear, and the conversational style which he employs is well suited to his subject.

Action des Rayons X sur les Glandes Surrénales. By Dr. PAUL COTTENOT. Paris: Vigot Frères. 1913. Pp. 172.

THIS book describes some clinical and experimental researches on the action of the X rays on the suprarenal glands. Acting on the principle of the inhibitory effect of the rays on gland tissue, the aim has been to reduce high arterial tension by irradiation of these glands from behind. The necessary details of technique are given, and also those relating to some 30 cases of hypertension treated in this way. An apparently permanent lowering of the tension was observed in some of these, but not in all. On the whole, the results would appear to be very encouraging, and promise a new and quite scientific method of dealing with a condition that frequently baffles all efforts.

Tuberculin in Diagnosis and Treatment. By FRANCIS MARION POTTENGER, A.M., M.D., LL.D., Medical Director of the Pottenger Sanatorium for Diseases of the Lungs and Throat, Monrovia, California. London: Henry Kimpton. Glasgow: Alexander Stenhouse. 1913. Pp. 243. Price 12*s.* 6*d.*

THE literature on the use of tuberculin is increasing at a rapid rate, but it is only by the accumulation of evidence that a definite opinion can be arrived at. Dr. Pottenger has had the advantage of watching his cases constantly, for nearly all of them were treated in a private sanatorium where the general conditions were of the best. He takes a broad view of tuberculosis and its treatment. Whilst he has been an ardent supporter of the use of tuberculin, he states that he has always reinforced it by every measure that would improve the physical and mental condition of the patient. He points out that the mere injection of tuberculin is not treating tuberculosis. He further maintains that tuberculin acts solely on the tuberculous process, affecting the general well-being of the patient indirectly; general hygienic and tonic measures and those that improve the mental condition of the patient, on the other hand, affect every organ and function of the body and act upon the tuberculous process indirectly. That is to say, the two are supplementary and both are essential to best results. It is of the greatest importance that these facts should be thoroughly grasped by all practitioners. Tuberculin is only one factor in the general management of tuberculosis, and to employ it alone without respect to common hygiene and due instruction of the patient as to the life he should lead can lead only to disappointment.

Another matter to which Dr. Pottenger rightly draws attention is the demand by many for an exact schema showing how tuberculin may be given by rule—namely, increasing the dose with a certain definitely stated rapidity and at definitely stated intervals. We agree with him when he says that those who expect good results from such routine use of the remedy will be disappointed. The effect of each dose should be watched and the subsequent ones administered accordingly. In discussing the value of tuberculin as a diagnostic agent Dr. Pottenger insists that a tuberculin reaction "in itself only indicates that tuberculosis antibodies are present. They may be due to an active, a quiescent, and, for a certain time after healing has occurred, to a healed lesion." We believe that the majority of physicians will agree that the tuberculin test for diagnostic purposes is not to be relied upon, as it does not distinguish between quiescent and active disease. Dr. Pottenger supports the proper administration of tuberculin as a therapeutic agent, but strongly deprecates its indiscriminate use. He earnestly advises all those who are intending to adopt tuberculin in the treatment of tuberculosis first to study the employment of the remedy with someone who has had experience in its use. With this advice we are entirely in accord, for in the hands of those who have not watched its manifestations in actual practice harm may result if the patients are not carefully selected and if the correct sequence of doses is not followed.

We are in accord with the part of this work which deals with the clinical details, but some of the theoretical considerations will probably need revision in a future edition.

The Student's Handbook of Gynæcology. By GEORGE ERNEST HERMAN, M.B. Lond., F.R.C.P. Lond., F.R.C.S. Eng., Consulting Obstetric Physician to the London Hospital. Second edition, revised by the author, with additions by R. DRUMMOND MAXWELL, M.D. Lond., F.R.C.S. Eng., Assistant Obstetric Physician to the London Hospital. With 6 coloured plates and 194 figures in the text. London, New York, Toronto, and Melbourne: Cassell and Co., Limited. 1913. Pp. 587. Price 7*s.* 6*d.* net.

THIS book is in reality a condensed edition of Dr. Herman's work on diseases of women, published at a third of the cost. The diminution of size has been obtained by omitting explanatory, argumentative, and speculative matter, references to rare cases, and descriptions of operations not commonly performed. Since, in revising the second edition of this handbook, Dr. Herman has made free use of the additions contributed by Dr. Drummond Maxwell to the fourth edition of the larger book, the latter's name has been added on the title-page. We have so recently expressed our favourable opinion of the original work in its fourth edition that there remains little to be said of this handbook. The condensation appears to have been made with discretion, and nothing has been left out which is really essential to the student. We have no doubt that students will welcome the opportunity of reading what Dr. Herman and Dr. Maxwell have to say on the special diseases of the female sex, and the book should enjoy a well-deserved popularity. It will certainly prove of value to the student, and, based as it is on a very large clinical experience, it should be particularly useful to him in his clinical work in the wards and out-patient department.

A Manual of School Hygiene. By EDWARD W. HOPE, M.D. Edin., EDGAR A. BROWNE, F.R.C.S. Edin., and C. S. SHERRINGTON, M.D. Cantab., F.R.S. New and revised edition. Cambridge: At the University Press. 1913. Pp. 311. Price 4*s.* 6*d.*

THIS excellent little book, the first edition of which was reviewed in THE LANCET of August 10th, 1901, is now presented in an enlarged form. When first published the book rather anticipated the requirements of the future and came almost before its time. Preventive medicine, school inspections, and infant consultations had not then attracted the great following they now command; but much has been accomplished since that date, and many excellent works have been published on the subject of school hygiene, so that much is expected of books which cater for the needs of school nurses, health visitors, and sanitary inspectors. The book is immensely strengthened by the six chapters on physiology which have been added by Professor Sherrington; but while it covers the ground required by the institutions

which grant diplomas in school hygiene and sanitary science a great deal is demanded of students nowadays, and it can hardly be claimed that it fulfils all the requirements, especially with respect to the elementary anatomy and physiology of the special senses and nervous system. The chapters on school buildings, ventilation, warming, school furniture, and writing are perhaps sufficiently full, but the same can hardly be said of those on the general functions of the body, which have been most admirably outlined by Professor Sherrington, but which are lacking in the specific details so eagerly looked for by intending examinees, who appreciate general principles and philosophic deduction less than hard, dry facts, which find but little place in the delightful reading supplied by Professor Sherrington. The book is far too good, we fear, to achieve a great popular success.

Handbuch der Vergleichenden Physiologie. Herausgegeben von HANS WINTERSTEIN. Lieferung 63. Band II. *Physiologie des Stoffwechsels.* Zweite Hälfte. Jena: Gustav Fischer. 1913. Pp. 305–480. Price 5 marks.

R. Burian continues his account of Excretion, and indeed approximately one-half of the whole text is given to excretion in worms, the old term emunctories being still retained for the excretory apparatus. Only in the case of a very few worms is a specific excretory apparatus absent, or at least has not been yet detected. A very full account is given of the researches of Keeble and Gamble on convoluta. The emunctories in plat-helminths and rotatoria are represented by a water-vascular system, in parasitic nematodes as lateral canals, and in annelida as segmental organs or nephridia. In this, as in other parts of the "Handbuch," there is an almost bewildering wealth of detail that can be appreciated only by professed zoologists, and indeed only by those zoologists who have made the group of worms a special study. References to the literature run into about nine pages. J. Strohl begins his account of the excretions in the mollusca, which occupies about 50 pages.

Maladies du Rachis et de la Moelle. Par MAURICE AUVRAY et ALBERT MOUCHET, Chirurgiens des Hôpitaux de Paris. Fascicule XIV. du Nouveau Traité de Chirurgie Clinique et Opératoire, publié sous la direction de A. LE DENTU, Professeur Honoraire de Clinique Chirurgicale à la Faculté de Médecine, et PIERRE DELBET, Professeur de Clinique Chirurgicale à la Faculté de Médecine. Avec 211 figures intercalées dans le texte. Paris: J. B. Baillière et Fils. 1913. Pp. 528. Price, paper, 12 francs; bound, 13.50 francs.

THE surgical aspect of diseases of the spine and spinal cord is one of increasing importance, not only by reason of the impunity with which surgical procedures in these regions are now undertaken, but also because of the fact that surgical intervention can often accomplish much where medical treatment is unavailing. In the present volume the authors have dealt with those diseases of the spine and cord for which surgical advice and skill are sought, and they have produced an excellent and succinct treatise on the subject.

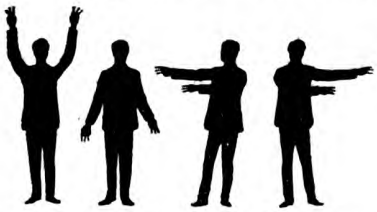
An introduction on the surgical anatomy of the parts concerned, and on normal physiology and pathology of the cord (we do not quite see why paragraphs on bulbar syndromes need be included), is followed by a full description of operative technique, in which the details of various operations as practised by well-known surgeons are supplied, including the intradural resection of posterior roots and lumbar puncture. Some 150 pages are devoted to traumatic disturbances, fracture dislocations, and wounds; other subjects to which much attention is given are congenital defects, spina bifida, congenital scoliosis, vertebral osteomyelitis, spinal tumours, Pott's disease, syphilitic and other forms of spondylitis. The chapter on circumscribed serous meningitis is rather inadequate, inasmuch as the section on its therapeutics consists mainly of excerpts from the work of other surgeons, and there is little indication either of the authors' own experience in this disease or of their opinion of the methods adopted by others. The attitude they assume in regard to the treatment of Pott's disease is unmistakably conservative. They are strongly opposed to surgical interference in any shape or form, and laud the results obtained on orthopædic and general lines.

The book as a whole is well calculated to supply the practising surgeon with modern information on the surgical treatment of the diseases of the spine and spinal cord.

LIBRARY TABLE.

Nervous Breakdowns and How to Avoid Them. By CHARLES D. MUSGROVE, M.D. Edin. Bristol: J. W. Arrowsmith. 1913. Pp. 188. Price 2*s.* 6*d.* net.—This little book, the motto of which might be taken to be "Prevention is better than cure," contains much commonsense advice on the education of the individual in the preservation of his health. What to eat, how to eat, how much to take, when to take it, fresh air, exercise, rest, sleep, recreation, holidays—these are some of the topics on which the author discourses, combining shrewd worldly wisdom with apt, if homely, illustration, so that he who runs may read. The business man might dip into this little volume with great advantage to himself; in fact, all who come under the stress of modern existence may cull from its pages simple truths and sound principles by which to regulate their lives.

How to Succeed as a Trained Nurse. Edited by Sir HENRY BURDETT, K.C.B., K.C.V.O. London: The Scientific Press, Limited. Pp. 192. Price 2*s.* 6*d.* net.—This little book bears as a subtitle "A Guide to her Remunerative Employment, with Particulars of the Various Openings in the United Kingdom and Abroad, Government and Municipal Departments, Associations, and Coöperations where the services of private nurses are in demand." This is a sufficient indication of the scope of the book, which is intended for all certificated and working nurses throughout the country. It is divided into two parts. The first consists of four chapters: The Private Nurse from the Employer's Point of View; Chief Branches of Nursing, their Openings and Prospects; Central Midwives Board; and Outline of the Principal Laws Affecting Nurses. An interesting point is made in discussing the question of a change of nurse when the patient's condition merges from that of acute illness into protracted convalescence. The strictly technical capacity, which was the main factor that influenced the medical man in choosing a nurse for an acute case, may be overshadowed in the later stages by a temperamental disability which, negligible in a critical stage, becomes a serious matter during convalescence. A nurse accustomed to a succession of serious cases may not fit well into the routine of family life and convalescence. In that event, the patient or the nurse, or both, may become restive, and a change in the "type" of nurse is recommended. The second chapter deals with hospital and Poor-law appointments, private, mental, district, village, monthly, and fever nursing, visiting nurses, army and navy nursing in all its branches, colonial and mission work, and so forth. The third describes the requirements under the Midwives Act; while the fourth gives useful pointers on engagement and dismissal, wages, gifts, testimony in courts, infectious diseases, and other matters, ending with a statement of the nurse's position under the National Insurance Act. The second part consists of a directory and detailed account of the various Government and municipal departments that employ nurses, of associations for the hire of nurses, British nursing



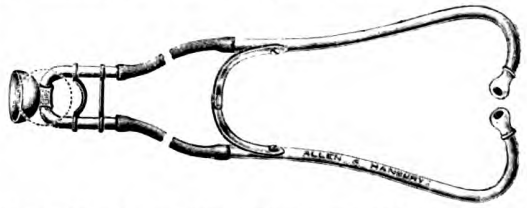
associations, a list of cottage hospitals and institutions employing nurses, and details as to provident funds, examining bodies, nurses' benefit societies, and so forth. Altogether a useful little book.

Messrs. Baillière, Tindall, and Cox ask us to state that they have been appointed the London publishers of Dr. L. Duncan Bulkley's "Diet and Hygiene in Diseases of the Skin" (New York: Paul Hoeber. 1913), reviewed in THE LANCET of June 14th, p. 1670.

New Inventions.

THE "SIGNAL" VISION TEST TYPE.

THIS test type has for its signs the Block E, after the fashion of Hirschberg's test types, but only one sign is given for each grade of the test. The signs are mounted on turntables, so that their positions can be varied indefinitely. In one model the whole of the turntables are geared together by a simple pulley arrangement so that the movement of a milled head at the front bottom edge of the board causes all the signs to turn in different directions. In the simpler model the turntables have knobs projecting behind the board by which they are moved as required. This test is of particular value where it is desired to make a subjective test of vision with a minimum of error due to the "mental factor"—e.g., in testing seamen, railwaymen, or other employees whose vision is a matter of importance, for this test requires no knowledge of letters, only the minimum power of imitation. The test has already been in use for testing school children for some time with



excellent results. As a school vision test the children are taught to regard the E sign as three fingers, turned up, down, to the right or left. The teacher draws these signs on the class blackboard in large size and teach the whole class "signal drill," showing them how to stretch out three fingers of both hands in the positions of the fingers of the E sign pointed to. After this drill vision testing is quick and sure. The test should be hung in full daylight (not sunshine); a monitor should stand beside the test holding a sheet of dull coloured card so as to cover all the signs below the one the child is looking at. The child should stand toeing a chalk line drawn at the distance of 16 ft. 6 in. from the test. The examiner sitting slightly behind the child will see both the signs and the signal of the child. The signs should be altered in position for each child by the monitor turning the milled head or one or two of the discs. Except that the test will get dirty there is no objection to letting it hang in the class-room, for it cannot be learned by heart. The illustration shows how the response is made. On the back of each test-card there is gummed a printed sheet with the instructions as above and a figure showing the manner of signalling with the arms and fingers.

The test is made in excellent fashion by Messrs. Curry and Paxton, Great Portland-street, London, W.

N. BISHOP HARMAN, M.B., B.C. Cantab.,
Harley-street, W. F.R.C.S. Eng.

A NORMAL ADJUSTABLE STETHOSCOPE.

THE advantages of this new pattern stethoscope I have found to be very great. The chest-piece is made of aluminium. The opening which receives the sound waves is twice the capacity of the two tubes leading to the external auditory meatus. The calibre of the instrument is perfectly equal all the way through, no interruption of any kind occurring either where the metal tubes join the tubing or where the tubing joins the chest-piece, owing to the specially constructed outside tapered knife-edge joints. The chest-piece is made to revolve, so that it is possible to examine the side or back to a very considerable extent without disturbing a very sick patient and without causing the tubes to kink or touch the bed-clothes, while the physician can examine all anterior parts, including the sides,

without changing position. The instrument is made portable by having the spring hinged, and it is of considerable advantage that the arms can be set up at a particular angle coinciding with the direction of the auditory meatus. The stethoscope has been tested and approved at various sanatoriums and hospitals in Great Britain and abroad. The rubber tubes are of especially heavy fine rubber, so that outside noises are excluded almost entirely and no vibrations are set up in the instrument itself at any point. It is termed a normal adjustable stethoscope because it conveys the sound waves emanating from the skin and underlying structures covered by the chest-piece without appreciable loss, without magnification or diminution of either the whole or any component parts making up the complex wave of sound, and without the production of adventitious sounds. While the heart sounds can be heard through the clothes such technique must be condemned. For children and very emaciated adults a localiser has been devised for use with the instrument, and this embodies the same principles on a smaller scale, thus making a very complete instrument. Great care should be used in getting ear-pieces that will fit and be comfortable.

The instrument is made by Messrs. Allen and Hanburys, Limited, Wigmore-street, London, W.

GORDON GROTE COPELAND, B.A., M.B.
Toronto, Canada.

AN IMPROVED MOUTH GAG.

THE illustration shows a modification of Doyen's incisor gag. The handles, which are straight, are hinged to the tooth pads by swivel joints, and can thus be swung over to either side of the mouth. I have found it very useful in enucleating tonsils with the guillotine by leaving an abso-

lutely free field at the angle of the mouth for the depression of the guillotine handles. During removal of the right tonsil the handle of the gag is swung to the right side, and of the left tonsil to the left side.

The instrument has been made for me by Messrs. Mayer and Meltzer, 71, Great Portland-street, London, W.

W. S. KERR, M.B., C.M. Edin., F.R.C.S. Edin.,
Honorary Surgeon, Ear and Throat Department,
Sheffield. Royal Infirmary, Sheffield.

THE LANCET.

LONDON: SATURDAY, OCTOBER 25, 1913.

A County Court Judge and Medical Referees.

A county court judge sitting recently in the Eastern Counties as arbitrator under the Workmen's Compensation Act was asked to summon a medical referee to sit with him as medical assessor in five or six cases which were to come before him. The applications thus made the learned county court judge declined to grant, and it will be just, before expressing disapproval of the course thus adopted, to quote in full the reasons which he assigned for it, as reported in the local newspapers. "There have been so many similar applications," he said, "that it may be well to state why I do not, as a rule, think fit to summon an assessor. It is not from any want of appreciation of the eminent doctors who would be called to assist me, and for whom I have the very highest regard, but the Act of Parliament does not mention any ground upon which the judge is to exercise his discretion in invoking such assistance, and reported decisions throw but little light on the subject. Even that little is of the negative kind. This much, however, may be gleaned from the reports. The position of a medical assessor is anomalous. He is not a judge. He is not a juror. He is not a witness. His communications to the judge are not made upon oath. He cannot be cross-examined upon them. They are not evidence of any fact. They cannot be used either to supplement, or to vary, or to contradict sworn testimony. His office is merely to masticate the medical pabulum for the judge. That is a function which judge and jury have long been in the habit of discharging for themselves and the public." The county court judge further intimated that if during the hearing of any matter a question arose which seemed to demand the consideration of a medical referee it could be submitted to such a referee and his report obtained before an award was made.

The concession is something, but it does not alter the fact that the county court judge refused to accede to the requests made by a large number of suitors who believed that in the interests of justice the whole of the medical facts relating to their cases should be laid as early as possible before a medical referee. That a county court judge has an absolute discretion in such matters assigned to him by the Workmen's Compensation Act we do not for a moment dispute, but we entirely fail to see why the absoluteness of that discretion should be advanced by him as a reason for declining altogether to employ the expert assistance provided for him without reserve by the legislature, or for dispensing with such aid against the expressed wishes of suitors. Nor does the rest of his reasoning strike us as in any way more cogent. No one would wish a technical assessor in a court of law to fill the position of a juror or a witness, or to be compelled to submit to cross examination; indeed, we fail to see how, in such circumstances, he would be rightly described as an assessor. A medical referee is not asked to contradict sworn testimony, but he may, we submit, be usefully consulted in the task of discrimination where sworn testimony relating to obscure medical matters is of a contradictory character. If courts of arbitration were constituted, presided over by medical referees, and if it were found in practice that arguments upon questions of pure law took place in them upon frequent occasions, surely no one would question the wisdom of appointing legal assessors to advise upon the decisions which might be given; and no medical arbitrator, knowing that important pecuniary considerations were involved, would refuse to accept whatever legal assistance might be placed at his disposal to deal with questions of law. The parallel suggested is a fairly close one. Under the Workmen's Compensation Act some of the most important issues to be decided, involving considerable sums of money to the parties, turn upon purely medical questions of a kind involving considerable medical knowledge if the correct solution of them is to be found. Applications to continue or discontinue awards afford examples which need hardly be dwelt upon in detail. In such cases, even with the fullest opportunities for inquiry and examination of the workman, medical witnesses may rightly advance conflicting opinions, and these and all other cases are rendered more difficult by the patient being a man or woman who may desire fraudulently to derive profit from a wrong decision being arrived at, or who may more or less honestly have deceived his medical man as well as himself as to his condition. Again, the question at the root of the whole matter, namely, whether the injuries or alleged injuries are the result of an accident at all, often presents difficulties which a lay arbitrator must necessarily be better able to decide with the help of absolutely unbiased expert advice, based upon appreciation of the medical points submitted on both sides. The "mastication of the medical pabulum" is a function which judge and jury have long been in the habit of discharging, but this does not bind us to the opinion that the function described has been satisfactorily performed in the interests of justice during the past, or that it is more likely to be so in the future.

Recent legislation, particularly in relation to workmen's compensation, has enormously increased the bulk of the medical pabulum submitted for mastication and deglutition in courts of law, and the development of medical science in all its branches, and in directions which a few years ago were unexplored, has equally exaggerated the complexity and the varied nature of the material to be assimilated. The institution of the medical assessor in a particular class of case was welcomed by many suitors as well as by medical men as an innovation likely to be followed as a precedent in future legislation—its result should be that medical evidence would be given before a tribunal capable of understanding it. It is in the interests of justice and of fairplay to litigants, whose cases may be no less just because they are not easy to be understood by laymen, that we are in favour of the extension rather than the curtailment of the system of medical assessors in

inquiries into medical facts. With regard to the weight assignable to the wishes of one or both parties that a medical assessor should be present we would add this. The party which has a weak case medically would be the one least anxious to submit it to a medical man for determination, just as the lawyer with a weak case legally, if he had the choice, would be less desirous than his opponent to have it submitted to a strong judge and a sound and learned lawyer. On the other hand, the party having, or believing himself to have, the stronger case medically—that is to say, the party desirous of having the true facts rightly understood and established—would be the one most anxious to see the function of "masticating the medical pabulum" thoroughly and efficiently fulfilled. And before any case is heard the parties know better than the judge what is the nature of the testimony which they are prepared to submit.

New Aspects of Diabetes.

PROFESSOR CARL VON NOORDEN, of Vienna and Frankfort, has contributed so largely to our knowledge of the pathology and treatment of diabetes that the clear and practical account of his views on these matters which he has given in some lectures delivered before the New York Post-Graduate School is of special interest. These lectures have been published[1] in book form and constitute a highly suggestive and interesting contribution to the literature of the subject. Professor VON NOORDEN believes that the control of sugar formation and of its distribution is situated in the liver, and that while the other organs elaborate and consume sugar they do not share in its production. He sums up the activities of the liver in regard to sugar as follows: the liver takes up the carbohydrates brought to it by the portal vein, and converts them into glycogen and perhaps into fat when there is great excess. If there should be a very rapid and copious supply of sugar to the liver a portion escapes conversion into glycogen, and gives rise to hyperglycæmia and subsequently to alimentary glycosuria. The intrahepatic decomposition of protein leads to sugar formation, though whether this occurs as a result of conversion of part of the protein itself into sugar or by stimulating sugar production is uncertain. Professor VON NOORDEN also brings forward evidence to show that if the available carbohydrates and the protein substances do not yield sufficient sugar for the needs of the moment, this substance can be formed from fat. Lastly, a diastatic process occurs in the liver by which the glycogen is reconverted into sugar. Normally the control of sugar formation in the liver results in a small supply to the blood during rest and a copious supply during work, and it is the need of the tissues for sugar which constitutes the supreme, and perhaps the only, factor in regulating the amount of sugar production.

In studying the influence of other organs upon the liver, the part played by the pancreas and the chromaffin tissues is most noteworthy. These organs exert opposing effects upon the excitability of the sugar functions of the liver: while the pancreas produces an inhibitory effect, the chromaffin tissues have a stimulating influence. According to Professor VON NOORDEN, other tissues exerting an influence upon the hepatic sugar functions do so indirectly through one or other of these two channels, the pancreas or the chromaffin tissues. It would appear, for example, that the nervous system acts in this respect chiefly through the latter; the nervous influence passes down by the left splanchnic nerve to the left suprarenal and thence to the right. CLAUDE BERNARD'S "piqûre" diabetes is in effect only an adrenalin glycosuria, resulting from a stimulation of the medulla causing a stimulation of the suprarenals. The thyroid acts, on the other hand, by inhibiting the excitability of the pancreas and the pituitary acts in like manner. Professor VON NOORDEN urges that failure to oxidise sugar in diabetes, which was the basis of some of the theories of that disease, has not been proved, and he maintains that there is over-production of sugar, and that its immediate cause is to be found in the over-excitability of the sugar-forming function of the liver. Normally over-production does not occur, the pancreas and chromaffin tissue ensuring accurate regulation. Briefly stated, his view of diabetes is that the sugar-producing functions work in an uncontrolled and wasteful manner and flood the blood with unnecessary material. He states that we have no grounds for assuming that the chemical processes leading to sugar formation in the liver are qualitatively altered in diabetes; the change is a quantitative one, due to a disproportion between the strength of the stimulus and the response of the sugar mechanism to it. He further believes that in all cases of chronic diabetic disturbance of metabolism pancreatic insufficiency exists, and he therefore supports the contention of the essential unity of diabetes in man.

The principles of treatment are carefully considered by Professor VON NOORDEN, who rightly urges the great importance of trying to lessen the condition of hyperglycæmia. He points out that if the urine is not permanently sugar-free, but from time to time contains even small quantities of sugar, then it is certain that there is hyperglycæmia. He has found that in diabetes the kidney becomes less permeable to sugar as time goes on, so that whereas at the beginning of the disease glycosuria appears when the sugar content of the blood is 1 per 1000, later the urine may be free from sugar although the blood may contain 1·5 per 1000. He considers carefully the influence of carbohydrate restriction and its effect in lessening the over-excitability of the sugar-forming apparatus. He discusses the use of oatmeal and its restrictions and the treatment of acidosis. While his views as to the pathology of the disease are admittedly speculative, they are based upon well-established experimental facts, of which they afford a more satisfactory explanation than many of the theories previously put forward. On the other hand, his views on treatment are the result of a very wide practical experience. We have read his lectures with interest and can commend them to our readers as being both instructive and practically useful.

[1] New Aspects of Diabetes: Pathology and Treatment. By Professor Dr. Carl von Noorden. Bristol: John Wright and Sons, Limited. London: Simpkin, Marshall, Hamilton, Kent, and Co. 1912. Pp. 160. Price 6s. net.

Anatomical Nomenclature and the Medical Student.

TRANSITIONS come about in strange ways, and it is characteristic of innovations, into whatever department of life they come, that however tardy and far removed from reality their initial stages may have seemed, their actual advent strikes one as something very sudden, very real, and very unconsidered. To-day it seems to the medical student that abruptly and all unconsidered a strange new-fangled set of anatomical names is being thrust upon him. To some extent he is justified in this belief, and yet the system of anatomical nomenclature known and disliked as the B.N.A. is no new thing, for nearly 20 years have gone by since the Basle *Nomina Anatomica* were drawn up for the use of anatomists. It is, however, only during the present year that the system has become widely adopted in the text-books most used by medical students; and there are already signs that the student does not intend to let the innovation pass unchallenged. An editorial article in the current issue of *St. Bartholomew's Hospital Journal* has raised the question in a very direct fashion, and it is likely that students in the London schools will not let the matter rest here. It may be well, therefore, to focus some of the points under discussion.

In the first place, the Basle *Nomina Anatomica* came into being because there was, and is, a real need to revise some of our anatomical terminology; so much is agreed on all hands. But in the second place the B.N.A. came into English text-books for commercial rather than for scientific reasons; so much is shrewdly diagnosed by the author of the article referred to. Although never being, and never claiming to be, a universal anatomical nomenclature, the system was taken up in America and in the Colonies at a time when the British anatomists as a body were holding aloof from it. Such a state of affairs naturally led to a diminution in the American and Colonial sales of the standard British text-books which still retained the old terminology. It matters not how eloquently the authors of text-books may plead the scientific gain of the so-called "new terminology"; it was the possibility of increased American and Colonial sales rather than the scientific gain that led to its adoption in the British text-books. Still, though the student may dislike the Basle system, and though he may dislike the manner of its being thrust upon him, he must be prepared for some reforms in anatomical nomenclature. The study of anatomy is an ever-advancing science, and the language of the anatomist must be a plastic one, capable of modification and extension in harmony with progressive discovery. There is no doubt that our old terminology needs revision, and there is also no doubt that the "new terminology," already nearly 20 years old, cannot be regarded as finality. Indeed, so far is this the case that a very wide demand exists for a revision of the Basle nomenclature, and the latest phase of the question is the serious attempt undertaken by British anatomists to organise an agreement between all English-speaking teachers for such a revision. Now although preliminary stages are progressing as rapidly as possible, it must necessarily take some years before the proposed revision for English-speaking schools is issued. It is safe to say that when this comes about a large number of B.N.A. terms will be deleted, or so far altered as to be unrecognisable, and the text-books written to-day in the terminology of the Basle agreement will be to some extent strange to a future generation of students.

It seems, therefore, that in the present scramble for issuing anatomical works in the new terminology an unwarrantable burden may be imposed upon the student. He may be learning names which are difficult for him to familiarise himself with, and which will be replaced by new ones in the not distant future; and he certainly has the right to ask if all this is being done for his good. He is told that it is his gain, that he may become conversant with current foreign literature, and thus more readily understand the anatomical contributions of other nations. But he knows quite well that in his student days he is aiming to equip himself for the practice of medicine and surgery, and not for the specialised career of a pure anatomist—a point which some of his teachers seem to overlook. Again, he is beginning to know that the B.N.A. is not a universal anatomical language, but is essentially a German-made code of somewhat restricted usage. He also knows, from the article already mentioned, that in its present form it is not likely to be the permanent code of English-speaking countries. The student is, in fact, beginning to think that he has not been sufficiently considered in introducing these changes; and there are already signs that he will have to be reckoned with in the future by the makers of books. It was the commercial demands of other markets that gave us the B.N.A. in our text-books; but it may be that the voice of the British student will yet determine the language of the anatomy he wishes to read. In the Charing Cross-road medical books are sold second-hand to London medical students. It is not the latest editions that are on sale there: and the demand for the older editions in the Charing Cross-road, equally with the demand for the latest editions in New York, must be taken into account if considerations of publishers' successes are to determine our anatomical terminology.

ANGLO-AMERICAN CONTINENTAL MEDICAL SOCIETY.—The annual dinner of this society was held in Paris on Oct. 18th at the Hôtel Majestic, Professor Robert Saundby, of Birmingham, being in the chair. The guests were Dr. du Bouchet, Dr. Castex, Dr. Desfosses, Dr. Galezowski, Dr. Lutaud, Dr. Field Robinson, and Dr. Mowat, and among the members of the club present were Dr. Eugene Dupuy, Dr. Koenig, Dr. Leonard N. Robinson, Dr. A. A. Warden, Dr. Magnin, and Dr. Robert Turner (honorary secretary). After the loyal toasts had been duly honoured the chairman proposed the "Prosperity of the Society," pointing out that it constituted a valuable link among Anglo-Saxon physicians practising on the Continent and the Mediterranean littoral, and served to maintain not only a friendly bond of union but the professional traditions which are honoured alike in England and the United States. The toast was responded to by Dr. Leonard Robinson, who also proposed the health of the honorary secretary.

Annotations.

"Ne quid nimis."

DR. HIDEYO NOGUCHI'S DEMONSTRATION.

AT a special meeting of Fellows of the Royal Society of Medicine on Monday, Oct. 20th, Dr. Hideyo Noguchi gave a most instructive demonstration of his researches on the spirochætæ and on certain bodies which he had found in the lesions of poliomyelitis and of rabies. The most interesting matter discussed by Dr. Noguchi was the statement that he had found the treponema pallidum in the brain of patients suffering from general paralysis. In the first series of 70 cases he had demonstrated their presence in 14 instances, and in a second series of 130 cases in 36 instances. The term parasyphilis has been used to denote those conditions which, although not directly syphilitic, are dependent upon its poison. Amongst the chief of these is general paralysis. Dr. Noguchi exhibited some microscopic specimens and lantern slides which showed very clearly the presence of the spirochætæ in the brain tissue. Further, he had been able to effect the transmission of the treponema pallidum from the brain of a general paralytic to the rabbit; also he had been able to produce symptoms and lesions resembling general paralysis in the rabbit by means of an intracerebral or subdural inoculation with treponema pallidum. As a result of these investigations it may be questioned whether general paralysis can any longer be regarded as a "parasyphilitic" condition, but should be placed amongst syphilitic affections, although it has not yet been definitely proved that all cases of general paralysis are due to the same origin, and it is probable that other factors are necessary in order that the brain can be attacked by the spirochætæ. Dr. Noguchi also showed lantern slides indicating that the spirochætæ multiplied by longitudinal fission. He further drew attention to the cutaneous reaction test for syphilis furnished by "luetin," which he considered superior to the Wassermann reaction. Another part of Dr. Noguchi's demonstration which caused much interest was his description of the "granules" which he found in pure cultures of the virus of rabies. In 1903 Negri described certain bodies which he found included in the cytoplasm of the nerve cells or in their branches, or occasionally lying outside them. Such bodies are found in the great majority of cases of rabies in the dog. Dr. Noguchi said that in the rabbit Negri's bodies could not be found, but "granules" could be detected. He showed a series of lantern slides showing Negri's bodies and also "sporulation" forms, which in cultures gradually grew larger and finally broke down into granules precisely similar to those which he had previously seen in cultures. He believed these "granules" to be the causal agent of rabies, although he was uncertain as to their exact nature. These observations appear to support those of Williams and Lowden,[1] who were able to demonstrate the presence of Negri's bodies at a very early stage, and considered them to be specific to rabies, and stated that they are found in large numbers in fixed virus; they further pointed out that very minute germs, barely visible under a 1500 diameter magnification, had been discerned, which were of such great plasticity that they readily passed through the comparatively large pores of Berkefeld filters; they looked upon these as living organisms and probably as belonging to the protozoa. Dr. Noguchi has brought this investigation to a most interesting stage, and further developments will be awaited with interest.

INSURED PATIENTS AND PROPRIETARY MEDICINES.

IN connexion with the administration of medical benefit under the Insurance Act, Local Insurance Committees are considering a question of no little difficulty. The problem they are called upon to solve is that of keeping the drug bill within the limits of the allotted amount without encroaching too much upon the prerogative of the prescriber. In some districts Local Committees find that unless the practitioners prescribe in a more economical way there will not be sufficient funds to pay the pharmacists in full and the committees are taking steps to discourage the prescribing of proprietary medicines. In a number of cases, in fact, lists have been drawn up of drugs and preparations which chemists may not charge to the Insurance Committees and which, therefore, panel doctors may not prescribe for insured patients. In other cases Insurance Committees without having given warning that certain articles should not be supplied have disallowed the charges for such drugs when the chemists have sent in their bills. Not unnaturally medical practitioners resent this action, and it is obviously unreasonable on the part of the committees to refuse to pay chemists for *bonâ fide* medicines which, in the absence of any warning to the contrary, they have supplied to an insurance practitioner's order. The kind of proprietary articles referred to are not, of course, the popular class advertised to the public, but branded products, for the most part of known composition, which are claimed to be, and often are, superior in one way or another to preparations of a similar nature but non-proprietary. Such branded products are regularly prescribed by practitioners in private practice, and the class includes some of the most valuable drugs known in medicine; on the other hand, the class comprises many preparations which are not materially superior to cheaper compounds of the British Pharmacopœia or other standard formularies. It is, however, obviously impossible for Insurance Committees to define those articles which are better than non-proprietary drugs and those which are not better, and in the circumstances the only proper course for the committees is to suggest to practitioners that before prescribing proprietary compounds they should take reasonable means to satisfy themselves that they are superior to similar products which are not sold under branded names. A short time ago the Scottish Commissioners, at the request of some of the Local Committees, issued a memorandum which now serves as a guide to the committees in Scotland. It is understood that the English Commissioners are considering the desirability of following this example. The Commissioners for Scotland in their memorandum divided "proprietary medicines" into two broad but mutually exclusive groups. One group comprised medicines the composition of which is not publicly disclosed—that is to say, those which are commonly known as "patent medicines" or "secret remedies." The second group comprised medicines the composition of which is made public without reserve, though the preparation may be made up in a particular form or sold by a special name. They expressed the opinion that preparations included in the first group were not in general "proper and sufficient drugs" in the sense of Section 15 (5) of the National Insurance Act, and should not be prescribed for or supplied to insured persons. On the other hand, they expressed the opinion that those in the second group should be supplied by chemists where ordered by panel doctors. The Scottish Commissioners added that they assumed that practitioners

would not order medicines in the second group unless they looked upon them as possessing recognised advantages over pharmacopœial or other non-proprietary preparations of similar composition. The Local Committees are not bound to act upon these suggestions, but in practice they are doing so, and it is very desirable that there should be more uniformity in the policy of English committees. It is obviously in the interests of insured persons that there should be no unreasonable interference with the duties of the doctor towards his patient.

CHILDBIRTH IN THE EIGHTEENTH CENTURY.

IT can scarcely be disputed that the eighteenth century held semi-barbaric views as to the puerperal state and wifely duties in general. When, for instance, Cæsarean section had to be resorted to, the mother was, when necessary, sacrificed in place of the child, whereas nowadays the mother, as a possible producer of further offspring, is spared and the child is sacrificed. The theory of the old medical jurisprudence was that everything should be done to safeguard the life of an heir; and a mother, as not being an heir, was as often as not the victim of her infant's claims to a succession. She was the slave of testamentary dispositions, and at times was compelled by these to give birth to her baby at some stated place. Often, again, during pregnancy she was made to suffer bitterly in the cause of dynastic or family feuds; and often, when no feud existed, she was bandied about during the period of gestation in a manner horrifying to modern notions of decency. It speaks volumes for our ancestresses that they apparently acquiesced with much cheerfulness in these arrangements. A historic document was issued in 1737 by George II. to all foreign ambassadors in England and to all British ambassadors abroad. Republished for the benefit of the public, it appears as the very scarce pamphlet entitled "Letters and Messages, that passed between the King, Queen, Prince, and Princess of Wales; on occasion of the Birth of the Young Princess." It was sold to a generation in sympathy with Frederick, Prince of Wales, for the sum of 6*d*., and presents a perfect picture of our ancestors' attitude towards a mother *in posse*. Late in July, 1737, the Princess of Wales, wife of the notorious, but not very wicked, Prince Frederick, had been to all appearances seized with labour pains and had been hurried at dead of night from Hampton Court to St. James's in order that she might become a mother in London. The roads were rough, footpads swarmed in the neighbourhood of what is now the Albert Memorial, the carriages even of the great hung on uneasy springs and ran on heavy iron tyres. Yet despite all this, Prince Frederick endangered his consort's life in order probably that the child might be born away from the Court and that the witty Queen Caroline might not be present at its birth. The supposition is that of Lord Hervey, whose fascinating memoirs have been so often quoted by Leigh Hunt in his description of the goings on at Kensington Palace when Queen Caroline resided there ("The Old Court Suburb"). On arrival at St. James's the beds were found to be unaired, and the only lady in attendance was a reputed mistress of the Prince. The pains, however, abated, and a return was made to Hampton Court. This happened on a Monday night or on a Tuesday morning. On the Friday following the pains returned, and again the Princess was rattled to St. James's, only to return to Hampton Court on a Saturday. On Sunday, however, there could be no doubt about her condition. She was got to London and gave birth to a princess, sister of the future George III. The Prince, writing in the curious Court French of the time, avers that there was no midwife at Hampton Court, and that neither Doctors Hollings and Broxholme nor Mrs. Hollings had diagnosed the near approach of the event during the Princess of Wales's flying visits to town. The King, however, was vastly incensed. He thought he saw through these excuses, and turned his son, his daughter-in-law, and their baby out of his London palace. Instances of babies untimely born are legion, for the ladies of the eighteenth century took risks with their eyes open and with a lightness of heart, now only to be equalled among gipsies or proletarians. In 1777, for instance, the wife of a naval officer, afterwards one of Nelson's admirals, narrowly escaped giving birth to her daughter in a theatre at Cork, where her versatile spouse was acting in the *Duenna*. He had a passion for the stage as well as for war at sea. "In the middle of the entertainment," according to the unpublished memoirs of the daughter in question, "my mother was taken ill, and escaped as quickly as possible and got home only a few doors distant, but no one was in to open the door. My father, guessing what had occurr'd, ran home in all his disguise and broke the door open before the servant could be awoke from a fainting fit into which she had fallen by reason of the heat." How our ancestors were born, and how they died, would form a fascinating volume, but mourners and survivors, from various motives, are always reticent as to these desirable data. Even in the case of famous medical men the cause of death is rarely mentioned. We know that John Hunter died from heart disease, but what did the great Joseph Henry Green die from when, like some hero of antiquity, he said "Stopped!" after his pulse had actually ceased to beat? If these deaths of famous men be obscure, how much more impenetrable are the circumstances of their births.

THE PERIOD OF GESTATION.

THE determination of the normal period of gestation is a matter of considerable practical importance, but up to the present time no very definite knowledge can be said to exist on this point. The problem is discussed by Dr. D. Berry Hart in the current number of the *Edinburgh Medical Journal*. An obvious difficulty is encountered at the outset of any inquiry on the subject in that the *terminus a quo*—the moment when the ovum is fertilised by the spermatozoon—cannot be accurately recognised, for it is almost certain that the male element may remain alive in the female passage for some days, while it is exceptional in the case of human beings to be able to trace a pregnancy to a single act of insemination on a known date. Hence it is necessary in the case of mankind to reckon the probable duration of pregnancy from a somewhat arbitrary date, that of the beginning or end of the last previous menstrual epoch. In the case of the domesticated animals greater accuracy is obtainable as to the time of coitus, and data are available as to the duration of pregnancy in both cattle and sheep. Regarding the latter Tessier's observations deal with 912 ewes, and it appears that labour took place in these between the 146th and 157th days after impregnation, a very large majority of all the births taking place between the 149th and 153rd days. If the figures are reduced to a curve in which the births form the ordinates and the dates the abscissæ a fairly symmetrical figure is produced, in which the axis of the curve corresponds with the 152nd day. It seems probable that in the ewe only one ovum is shed at a time, and that some, at all events, of the variation in the actual date of the occurrence of labour is due to differences in the time taken by the spermatozoon to meet the ovum. It may be noted that as the *terminus ad quem* is the actual birth, and the process of labour may be prolonged, another variable

factor is introduced at the end of the calculation. In the case of cattle observations were recorded by the fifth Earl Spencer, which show a range of time extending from the 220th to the 313th day after insemination, but as, according to Dr. Hart, calves are to be regarded as premature before the 260th day, the period of variation is rather less than this. If these figures are also reduced to a curve, again a fairly symmetrical figure is produced, the maximum number of births lying between the 284th and 285th days. It seems legitimate to conclude that, as might be predicted in a vital process, the duration of gestation is not a rigidly fixed period, while the greater range of variation in cattle as compared with sheep may be explained by assuming that in the former two ova may be shed at intervals of three weeks, and that either one or other may be fertilised at any particular act of coitus. Figures as to the duration of human pregnancy have been collected by several observers, notably by von Winckel and by Reid, who calculated respectively from the first and last days of the preceding menstrual period. Curves prepared from their data again show fair symmetry, the range found by von Winckel being from the 258th to the 313th day, and by Reid from the 252nd to the 316th. The maximum number fell in the former author's experience between the 282nd and 289th days after the first day of the last menstruation; in that of the latter between the 276th and 279th day after the cessation of the period. It is clear that we are not in a position at present to predict with any accuracy the probable duration of an individual pregnancy, and that further observations are desirable. Dr. Hart suggests that "more exact results might be obtained officially under the Insurance Act" if the dates of beginning and end of the last period of menstruation and the date of labour were recorded on the official cards which have to be prepared in order to establish a claim to maternity benefit.

ALTITUDE AND BLOOD VOLUME.

THE increase in the number of red blood corpuscles in animals and man living at high altitudes is a well-established fact. Animals living in Mexico at 3700 metres have double the normal number of red corpuscles, and Viault found 6 to 9 millions per cubic millimetre in Peruvians dwelling at over 4000 metres. Müntz kept rabbits in the summit of the Pic du Midi for seven years, and found that the iron percentage of the blood increased from 40·3 on the plain to 70·2 milligrammes at the summit. There is also an increase in the hæmoglobin percentage in the blood. These results have been ascribed to various causes. This week we print a communication on the Effect of Altitude on Blood Volume by Professor G. Dreyer and Dr. E. W. Ainley Walker. From this it appears that there are also definite changes in the blood volume, which follow definite laws. Bohr observed that diving birds which remain several minutes under water have double as much blood as ordinary birds. The authors have analysed the "almost inexhaustible wealth" of the information recorded by Abderhalden from observations on rabbits kept at St. Moritz from four and a half to eight weeks, 1856 metres above sea level, in 1902, and they are led to the conclusion that the change of volume which occurs with a particular change of barometric pressure is proportional to the area of the body surface in different individuals of a given species. The blood volume is diminished by an amount exactly proportional to their body surface. In the St. Moritz rabbits the diminution of blood-volume was nearly 11 per cent.; the hæmoglobin shows an increase and the number of red cells a parallel increase. The increase of the hæmoglobin reaches 11·7 per cent. of the total hæmoglobin. This shows that there is an active new formation of blood during a temporary residence of some weeks at high altitudes. The increased oxygen capacity is as regards one half due to concentration of the blood and as to the other half to new formation of hæmoglobin and red cells. In the early days of the sojourn the whole change is due to diminution of the blood volume. The authors are not in agreement with some of the conclusions of Douglas, Haldane, Henderson, and Schneider from their observations made on Pike's Peak (3386 metres). When the St. Moritz rabbits were brought back to Basel the blood volume reached the Basel normal in four days, and after the third day and onwards the daily fall in oxygen capacity ran parallel to the fall in percentage hæmoglobin. A formula is given for the calculation of the volume of blood in mammals, and the authors find the same formula applicable to certain birds which they name. This relation between blood volume and surface area of the body of mammals and birds is related to the fact that they are homoiothermal animals or animals of constant temperature. In poikilothermal animals, such as a frog and lizard, the blood volume is neither proportional to the body surface nor to the body weight. The blood volume increases as the animal grows heavier, while in warm-blooded animals there is a steady diminution. Professor Dreyer and Dr. Ainley Walker also find that the ratio of the weight of the heart muscle—in different species—to the total oxygen capacity is approximately constant from species to species in a number of instances. One of the other interesting results is the comparison of the hare and wild rabbit to show the importance of life and muscular activity as a factor in determining the amount and the distribution of the hæmoglobin in the body. Animals with a high hæmal hæmoglobin have usually dark-coloured muscles and a high hæmoglobin percentage in their skeletal muscles; those with a lower hæmal hæmoglobin percentage have pale muscles. The hare as compared with the wild rabbit has remarkable speed, greater endurance, higher hæmoglobin percentage, darker muscles, a heavier heart, and a larger aorta. The hare has more than double the amount of blood, 30 per cent. more hæmal hæmoglobin, and about three times as much heart muscle as a wild rabbit. These and other facts recorded in this communication offer fruitful suggestions for more extended investigation into the important question of blood volume.

AN INSTRUCTIVE MISTAKE.

ONE of the valuable features of the *British Journal of Surgery* is a series of cases published anonymously under the heading of "Instructive Mistakes." In the following case a distended saccule of the bladder was mistaken for a cæcal volvulus. A man, aged 79 years, in fair general health, who had not suffered from any urinary symptoms, was seized with abdominal pains and urgent vomiting, which was copious and projectile. The pains were paroxysmal and referred to the lower abdomen, especially to the right iliac fossa, where a firm elastic swelling could be seen and felt. During the pains it hardened palpably. It was only relatively dull on percussion, and there was no obvious hypogastric fulness. The bowels had acted regularly, and after enemata fæces and flatus ceased to be expelled. Purgatives could not be retained on the stomach and therefore failed to act. The prostate was much enlarged, but there was no cystitis. As urine was passed occasionally and instrumental aid did not appear to be required no catheter was passed. There was no general abdominal distension or tenderness. Volvulus of the cæcal region was diagnosed and laparotomy was performed, when the swelling was found to be a large distended saccule of a deformed bladder. The whole length of the intestines was examined methodically without finding any obstruction. An elbowed catheter was passed and the

swelling disappeared and this instrument was used daily in the subsequent treatment. The wound healed by first intention. After the operation the vomiting continued, with occasional hiccough, but was not so urgent as when the bladder was distended. Purgatives acted at intervals satisfactorily, and the bladder was washed out daily. The general condition did not improve, and death took place six weeks after the operation from uræmic coma. Had a catheter been used before the operation, the distended and deformed bladder would not have been mistaken for a volvulus. An examination of the urine for low specific gravity and diminished excretion of urea would have led to the conclusion that the vomiting was uræmic, doubtless produced by chronic retention of urine and atrophy of the kidney, the result of back pressure maintained by the prostatic hypertrophy.

PAROXYSMAL ŒDEMA OF THE LUNGS.

FOUR cases of a condition which, though not very rare, has received scant attention in the text-books--paroxysmal œdema of the lungs—are reported by Mr. C. E. S. Flemming in the *Bristol Medico-Chirurgical Journal* for June. The pathology of this condition is somewhat obscure, but its clinical features are very definite. Mr. Flemming gives the following excellent description. The attack usually commences with some irritation in the throat, tickling, and a feeling of dryness with slight cough. There is a fear that something serious is happening; in later attacks this fear amounts almost to terror. The patient cannot, dare not, lie down. Breathing at once becomes rapid and the face looks anxious and pale. The skin is cold and moist. The cough grows more distressing, and frothy, coagulable fluid, frequently blood-stained, is expectorated. The chest is rapidly filled with râles. The pulse is small and quick. The breathing becomes more distressing, and the expectoration at times becomes more profuse. This condition lasts from half an hour to an hour and a half. Gradually the breathing becomes deeper, easier, and quieter, the pulse fuller and less rapid, and the skin resumes its normal colour and warmth. The patient is thankful for the relief, but too apprehensive of recurrence to sleep soundly. Air now enters the chest freely, but râles persist over the greater part of one or both lungs. In one or at most two days all signs of œdema disappear, and the attack has passed off to return, it may be in a week or two or not for months. The onset is nearly always at night, within two or three hours of bedtime. Mr. Flemming has never been able to satisfy himself as to an exciting cause. An attack was generally attributed to one of those things which happen so frequently that they were possibly mere coincidences—e.g., worry, excitement, a cold wind, a hot day, fatigue, some food that might have disagreed, a crowded room, going upstairs. The four patients were equally divided between the sexes. The youngest was a woman, aged 54 years, and addicted to alcohol. She had a high-tension pulse, and a trace of albumin in the urine. The first attack passed off rapidly. A month later another occurred, and although the lungs cleared up quickly the general condition was not good, and she remained weak and the pulse continued fast. Ten days after the second attack the lungs were quite clear and she seemed decidedly better. Mr. Flemming had not left the house two minutes when he was called back and found her struggling for breath. There were râles all over the chest, and watery fluid was freely expectorated. She became deeply cyanosed and died in two hours, apparently from heart failure. Another woman, aged 70 years, was the hard-working wife of a labourer. She had mitral incompetence for six months and thickened arteries, but no albuminuria. Typical attacks occurred at intervals of a few weeks. After a few months she became distressed and drowned herself. In a man, aged 68 years, there were an apex beat in the nipple line, thickened arteries, a pulse tension of 180, a good deal of dyspnœa, and palpitation on exertion. He was a heavy smoker and eater. Two paroxysms of œdema occurred at an interval of about a month, and the second was fatal. The longest case occurred in a man aged 71 years. For two or three years he had shown various evidences of arterial degeneration. The blood pressure was 140 and the urine normal. For two years the attacks occurred at irregular intervals, and he eventually died of heart failure. In this case the attacks were followed by dulness over the lower half of the right chest. The condition present in these cases is frequently termed acute œdema of the lungs, but paroxysmal œdema is a better name, as it is thus distinguished from the acute œdema of pneumonia, influenza, mitral disease, and Bright's disease. Mr. Flemming points out that in its mode of onset and in the general appearance of the patient the condition bears a curious resemblance to cardiac asthma, but is much more alarming. Various theories have been advanced to explain it. The most plausible is that the left ventricle fails to contract properly, so that with every beat it passes on less blood than the right. The result is that the pulmonary vessels rapidly become engorged. Professor Welch produced acute œdema in the rabbit's lungs by squeezing the left ventricle and so paralysing it. As the descriptions given show, there is clinical evidence of failure of the left ventricle. With regard to treatment, Mr. Flemming found that nitrites in any form were useless, which the view of the pathology given explains. Hot fomentations gave some relief, but did not seem to cut short an attack. Of the value of stimulants there was no evidence. Oxygen given freely gave decided relief and seemed to shorten the attack. But nothing gave such relief as hypodermic injection of morphine and atropine.

MOONLIGHT AND DECAY.

THE observation that the rays from the moon favour putrefaction detracts from the romance which has long been associated with moonlight. It is an old tradition that to sleep in the moon's rays was a dangerous proceeding, and there is such a thing as "moonblink," a temporary blindness said to be due to sleeping in the moonlight of tropical climates, while some observers have reported a devitalising action of the moon's radiations on vegetable life. There is even quoted a death the cause of which was officially stated to be exposure to moonlight. Apparently the food most seriously affected by the moon's radiations is fish, and seemingly trustworthy statements have been made as to the ill-effects produced in persons who had partaken of fish which had been freely exposed to moonlight. Mr. E. G. Bryant, B.A., B.Sc., writing in a recent number of the *Chemical News* from Port Elizabeth, South Africa, suggests that a possible explanation of these phenomena, assuming them to be true, might lie in the well-known fact that the light of the moon, being reflected light, is more or less polarised, and possibly polarised light may exert a peculiar chemical action. Subsequently, polarised light was obtained from a powerful metallic filament lamp, the light being polarised by means of a pile of sheets of plate glass backed with silver and placed at the correct angle. The experiments showed certain marked results when fish was submitted to the polarised light obtained in this way, although it is probable that stronger effects would be obtained with a more powerful source of light. When two slices cut from the

same fish were hung, one in the direct light and the other in the polarised beam, the latter invariably began to decompose before the former, though the temperature of the polarised beam was several degrees lower than the direct light. There were indications also in the case of other perishable food substances of a tendency to decompose when they were bombarded with polarised light. The question is worth further investigation, and there should be little difficulty in pursuing such a line of research. There are so many influences ascribed to moonlight that it would be of obvious interest to have some scientific evidence tracing a definite action to the rays. It would be curious to find that such terms of obloquy as "moonstruck," "mooney," and "moonshine" were after all not entirely empirical.

INTUSSUSCEPTION OF THE STOMACH AND DUODENUM DUE TO A GASTRIC POLYPUS.

THE case recorded by Mr. Henry Wade of Edinburgh, in *Surgery, Gynæcology, and Obstetrics* for August, is of singular interest, both in respect of its nature and the successful issue of the treatment adopted. The patient, a married woman aged 48, being seized with acute abdominal symptoms in May, 1911, was operated on in the Edinburgh Royal Infirmary; the gall-bladder was emptied of stones and drained, and an acutely inflamed appendix was excised. She was well for some weeks after a normal post-operative convalescence, but had to return to hospital in August, 1911, suffering from severe epigastric pain associated with vomiting. This attack passed off, and she went home again, to find that any freedom of diet brought on similar symptoms, and that in spite of precautions pain and vomiting were apt to recur. During 1912 her troubles became aggravated and she lost flesh; at this time a fulness was noticeable in the epigastrium, with a peristaltic wave travelling from right to left, which was interpreted as indicating obstruction to the transverse colon by an omental band. Her general state at length became so precarious that a laparotomy was undertaken. This discovered the nature of the swelling that had been palpable; it was a recent intussusception distending the uppermost six inches of the jejunum. This was eventually found to owe its origin to a pedunculated myoma of the gastric wall, which had been carried through the pyloric ring into the duodenum, dragging with it a substantial portion of the wall of the stomach, and in the duodenum it had stuck fast. The consequence was that the duodenum, which was abnormally mobile, had been forced on into the upper jejunum. It was easy enough to reduce this intussusception, but the tumour was dislodged from its impacted position within the duodenum with some considerable difficulty. Eventually this was accomplished, and the tumour, which was as large as a duck's egg, was successfully removed, together with the portion of the gastric wall to which it was attached. The subsequent history of the patient's career is not detailed, but Mr. Wade claims that this case is the only one on record in which operative treatment of a gastro-duodenal intussusception was successful. A review of the literature of the subject shows that a majority of benign gastric tumours become pedunculated sooner or later, constituting intragastric polypi. These, if situated near enough to the pylorus, cause an intermitting pyloric obstruction with the appropriate symptoms. A natural cure may result, the polypus becoming detached, and in the intervals between the attacks the patient is in fair health; but, nevertheless, if the presence of a gastric polypus in the central portion of the stomach should ever be diagnosed it should be removed by operation. Whether such a diagnosis has ever been made does not appear from Mr. Wade's summary of the records, but the probabilities of such a condition being present in any given case of pyloric obstruction are so remote that he would be a bold man indeed who made the diagnosis of gastric polypus unless he held the tumour in his hand.

METHOD FOR DETERMINING THE TOXICITY OF COAL-TAR DISINFECTANTS.

Dr. Worth Hale, assistant pharmacologist in the United States Public Health Service, has submitted a report on a method for determining the toxicity of coal-tar disinfectants, together with a report on the relative toxicity of some commercial disinfectants.[1] The method consists in injecting a series of mice with varying amounts of the substance until the least fatal dose is determined. Mice of the same lot are similarly injected with dilutions of pure phenol and the least fatal dose per gramme of body weight determined as above. The dose thus obtained with pure phenol is considered unity, and the least fatal dose of the substance in question is estimated as a percentage of this. The determination of the toxicity coefficient by this method is a continuation of the work done by Dr. T. B. McClintic in estimating the phenol coefficient of a number of commercial disinfectants. Proceeding on the lines indicated, Dr. Hale found that all of the disinfectants that were alleged to be harmless or were labelled non-poisonous are toxic towards mice, and other experiments showed them to be poisonous to guinea-pigs and cats in approximately the same degree. He holds that the same relation probably exists for man, and statistics of human poisoning by compounds of this nature give confirmatory evidence of their inherent toxic properties. Of the disinfectants claimed to be non-poisonous examined by Dr. Hale were tricresol, with 90 per cent. toxicity compared with phenol at 100 per cent.; lysol, 56 per cent.; zenoleum, 19 per cent.; Pearson's creolin, 18 per cent.; and chloronaphtholeum, 16 per cent. The coal-tar disinfectants of the phenoloid group were found to be considerably less toxic than either phenol or the cresols. But they are not harmless, non-poisonous substances, for they have a toxicity equal to from 15 to 20 per cent. phenol.

TREATMENT OF PYORRHŒA ALVEOLARIS.

THE valedictory address of the retiring President of the Odontological Section of the Royal Society of Medicine alludes, among other matters, to one which at times becomes a burning question between the dentist and the physician—the need for radical treatment of pyorrhœa alveolaris. Mr. P. Sidney Spokes points to the divergent views prevailing in his own profession as to this trouble. Some dental surgeons maintain that it is necessary to extract all teeth which show any separation of the gum around them, owing to the danger of future stagnation of food remnants and resulting infection, while others hold that even when there is actual pyorrhœa of moderate extent extraction of all the teeth, as often practised, is unjustifiable. We hope that the attention drawn to the matter will lead, at all events, to agreement among dental practitioners as to the cases in which radical operation is ideally necessary from a dental point of view; but another question which is of more immediate medical importance may arise as to the influence of total, or almost total, removal of the teeth on the general health of a patient and on the course of some constitutional disease. It is in relation to cases of pulmonary tuberculosis that the question becomes most acute, since in recent years much stress has been laid on the evil effects of pyorrhœa upon sufferers from this affection; and it is customary to recommend a thorough dental overhaul before residence in a sanatorium.

[1] Bulletin No. 88, Hygienic Laboratory, Washington, D.C., pp. 46.

It may then happen that the dentist advises extraction of all the teeth, a procedure to which the patient may not unnaturally raise objection; and it falls to the lot of the physician either to insist on the need for this radical measure or to place himself at variance with his dental colleague. Now, not only may the actual procedure involve a serious tax on the patient's strength when already ill, but in the case of a poor person the provision of artificial dentures may be financially impossible. Yet while in an edentulous condition he may be unable to take the amount of food which is requisite for his subsistence and recovery. Time will doubtless bring about agreement as to the course which should be pursued, but meanwhile it seems probable that a tuberculous subject is better off with a small amount of pyorrhœa and an adequate supply of teeth to masticate his food than with a perfectly clean set of gums and no teeth to eat with.

TUBERCULOSIS IN TRINIDAD AND TOBAGO.

A COMPARISON of the incidence of pulmonary tuberculosis in various parts of the world is always of interest and leads to increased knowledge of the disease, especially as regards its virulence and mode of spread amongst the inhabitants of different countries. At the West Indian Inter-Colonial Tuberculosis Conference, held in Trinidad in March of this year, Dr. George H. Masson read an interesting paper on Tuberculosis in Trinidad and Tobago. He stated that tuberculosis, mainly of the respiratory organs, is widely prevalent in the colony of Trinidad and Tobago. In Trinidad its incidence is highest in the county of St. George, which is situated in the northern division of the island and includes the town of Port-of-Spain. He considered the principal cause of the wide dissemination to be direct contagion, resulting from the multiplicity of households which are both overcrowded and infected. He drew attention to the fact that the same active causes of tuberculosis denounced by Sir Alexander Tulloch (an army medical inspector) and others in the early part of the last century still persist, and are responsible for the same excessive prevalence of the disease reported upon in days when preventive medicine was still unknown to science and the bacillus of Koch as yet undreamt of. In the absence of direct measures for the control of tuberculosis and for the eradication of the causes which have favoured its spread in the colony during the last century the carriers of infection have become very widely disseminated among the population; and owing to the method of living each sufferer from tubercle is successful in breeding fresh carriers for the propagation, if not the perpetuation, of the disease, so long as there is continued delay in adopting the proper methods of defence. Another factor of great importance is the special susceptibility to tuberculous infection of the negro race from which the majority of the population has sprung. We support Dr. Masson in the view that the recognition of this proneness of the negro race to infection is an important matter which should further urge the responsible authorities to make efficient use of the weapons which medical science has placed in their hands to prevent the continued deterioration of the labour efficiency of the masses of the people whose health and strength are assets of great value in agricultural colonies. Dr. Masson believes that besides the question of racial susceptibility there also exists in the colony a general lowering of resistance to lung affections common to European and native alike. This he ascribes to the climate, in which, as in many other tropical countries, excessive heat and a high degree of atmospheric humidity appear to have a prejudicial influence upon the respiratory organs. As regards the actual prevention of tuberculosis in the country, there are as yet no official regulations in force for dealing with that question, but in 1905 the Trinidad Association for the Prevention and Treatment of Tuberculosis was founded, and this association is doing excellent work, as is shown by the eighth annual report which has recently been issued. It is earnestly to be hoped that some working plan for attempting to stamp out tuberculosis from the colony will be devised and that official aid will be forthcoming to render the necessary steps feasible.

WE much regret to learn, as we go to press, of the sudden death of Dr. Lucas-Championnière, on the afternoon of Oct. 22nd, during a meeting of the Institut de France.

THROUGHOUT the medical profession the greatest sympathy is felt with Sir Almroth Wright on the tragic death, following an accident, of his eldest son at Dublin on Sunday last.

Surgeon-General Sir R. Havelock Charles, G.C.V.O., will present the prizes at the Royal Army Medical College, Grosvenor-road, S.W., on the conclusion of the 106th session, on Wednesday next, Oct. 29th, at 4 P.M.

THE fifth Norman Kerr lecture of the Society for the Study of Inebriety will be delivered by Sir Thomas Clouston, M.D., on Monday, Nov. 3rd, at 4 P.M., in the Hall of the Royal College of Physicians, Queen-street, Edinburgh. The subject of the lecture is the Clinical Aspects of the Study of Inebriety.

THE LONDON COUNTY COUNCIL AND MEDICAL AFFAIRS.

The Local Government Board and the Treatment of Tuberculosis.

A LETTER from the Local Government Board in reply to a request by the London County Council for a statement of the views of the Board with regard to the administration of treatment of tuberculosis in London[1] was reported to the Council on Oct. 21st. The Board stated that it still held the view previously expressed that the London County Council should be the tuberculosis authority for the metropolis, and that through the Council all the various agencies should be properly coördinated to form parts of a complete scheme of institutional treatment for this disease. It was essential that the dispensary arrangements should be closely related to the preventive work which it was the duty of the sanitary authority to carry out, and there were many advantages in regarding the metropolitan borough as the unit area for dispensaries. Accordingly, the Board had invited the metropolitan borough councils to provide, or arrange for the provision of, these institutions. The Board agreed with the view contained in the resolution of the County Council that all possible use should be made of existing institutions; in the Board's opinion any hospitals or other voluntary institutions which were to be recognised as forming part of the tuberculosis scheme for London should be willing to work in close coöperation with the local authority. The Board agreed with the County Council in thinking that as far as practicable arrangements should be made for referring any specially difficult cases from a municipal or voluntary dispensary to some general or special hospital. In particular, the Board desired to learn what general rules the County Council would suggest should be observed in the working of the various local dispensaries so that the work performed by these institutions might properly form part of the whole scheme for London.

As regards residential accommodation, the Board considered that upon the County Council should rest the responsibility of securing that the necessary accommodation

[1] THE LANCET, August 23rd, p. 585.

was available. Much of this accommodation could, no doubt, be provided economically and efficiently by the Metropolitan Asylums Board in pursuance of an agreement between the London County Council and that body. It might also be possible that the County Council could arrange with some of the great London hospitals to provide beds for special cases. So far as insured persons and their dependents were concerned, agreements with the Metropolitan Asylums Board might be made in pursuance of the provisions of Section 39 of the National Insurance Act, 1913. As regards the rest of the community, the Board was disposed to the view that arrangements with the Metropolitan Asylums Board could also be made by the County Council under the provisions of Section 3 of the Public Health (Prevention and Treatment of Disease) Act, 1913, and Section 80 of the Public Health (London) Act, 1891. The accommodation to be provided was to serve both the insured and the non-insured, and the London County Council should consult with the London Insurance Committee as to the arrangements required for insured persons and as to the payments which the London Insurance Committee would make for the services provided for such persons.

The Departmental Committee made the suggestion that each area should have a chief clinical tuberculosis officer who should also act as medical adviser to the Insurance Committee of that area, and the Board suggested that the London County Council should carefully consider whether this arrangement might not be carried out in the case of London. This officer might also, in consultation with the other medical men concerned, supervise and generally direct the selection of cases to receive residential treatment.

As regards the financial arrangements to be made, it seemed to the Board desirable that the cost of the scheme, at any rate to a large extent, should be borne by London as a whole. Inasmuch, however, as the dispensaries were to be provided locally, some proportion of the cost of providing these institutions should be charged locally. It would simplify matters if, as regards the treatment of insured persons, the County Council were recognised as the providing authority for all the institutional treatment required, whether in dispensaries or other institutions, so that the London Insurance Committee could make one agreement with the London County Council in regard to all the services rendered to insured persons.

The Board stated that it would be happy to arrange for a further conference with representatives of the County Council if it should be considered that this would facilitate the formulation of a general scheme for the metropolis.

In some observations on the letter the Public Health Committee remarked that during the time the Council had been engaged in the preparation of a comprehensive scheme the Local Government Board, without reference to the Council, had approved local schemes prepared by the local sanitary authorities for the provision of dispensary treatment. It had thus been rendered very difficult, if not impossible, for the Council to organise a comprehensive scheme for London. In order, however, to avoid further confusion and inequality of treatment the committee thought the Council should agree, so far as dispensary treatment was concerned, to act to some extent on the lines suggested by the Board. All local schemes should be submitted to the Council in the first instance and, so far as uninsured persons were concerned, contributions in relief of local rates, subject to certain safeguards, should be made out of the county fund. In cases in which the Council disapproved of a local scheme and the local authority concerned refused to make amendments to meet the Council's objections the committee thought that the Council should make no contribution. Through the medium of finance the Council would be enabled to secure a measure of control which could now be obtained by no other means. The committee was unable at this stage to put forward even an approximate estimate of the expenditure which would fall upon the county rate if the proposal was adopted. From details available of the estimated cost of certain local schemes, the annual charge on the county rate might amount to upwards of £10,000.

The committee recommended the Council to pass the following resolution :—

That any comprehensive scheme for dealing with the treatment of tuberculosis in London shall provide for a contribution being made by the Council from year to year towards so much of the cost of the dispensary treatment of uninsured persons in the City of London and each metropolitan borough as would otherwise fall on the local rate, after taking into account the promised grant from the Imperial Exchequer, provided that such contribution (1) shall not exceed 50 per cent. of such cost; (2) shall in the first instance be made from a date to be fixed hereafter by the Council; and (3) shall be conditional upon the Council being satisfied with the local scheme in force in such area and to the arrangements and expenditure being annually submitted to, and approved by, the Council.

Consideration of the report was postponed.

Proposed Licensing of Lying-in Homes.

The Midwives Act Committee presented a further report as to the proposed legislation for licensing lying-in homes.[2] The committee stated that it did not appear necessary or desirable that the Council's powers of licensing should extend to Poor-law institutions or important hospitals or to a private residence in which a relative of the occupier was received for her confinement. Such places should be excepted from the proposed legislation. It was necessary also, having regard to the variety of institutions and places concerned, that the Council should retain the right to make certain other exceptions. There was still in force an Act of George III. which required certain lying-in institutions to be licensed by the justices in quarter sessions. This Act was practically obsolete, and it might be found necessary to repeal or amend it. In the event of the Council obtaining the power now sought the additional cost involved, in the first instance at any rate, would be small, and the appointment of one female inspector at a salary of about £100 a year would probably be sufficient.

The Council decided to promote legislation on the lines indicated above, and at the same meeting decided to take further steps towards the promotion of legislation for the control of massage establishments.[3]

MEDICINE AND THE LAW.

Sloman v. *The British Medical Association and Others.*

AT the recent Bedford assizes Mr. Justice Rowlatt with a special jury tried an action brought by Mr. H. Sloman against the British Medical Association, Dr. G. Butters, Dr. G. H. Goldsmith, and Dr. S. J. Ross. The case arose out of the proposed purchase by the plaintiff of the practice of a medical man at Bedford in 1907. Mr. Sloman went to Bedford from Edinburgh in order to complete the purchase and take over the practice, but an accountant, after going through the vendor's books, reported that the average income of the practice was less than the vendor had represented it in his advertisements, and the plaintiff declined to proceed further. He had, however, taken his furniture from Edinburgh, and he decided to remain at Bedford and endeavour to obtain a practice without purchasing that of the vendor or any other. This conduct was resented by the other medical men practising at Bedford. The central ethical committee of the British Medical Association was applied to, and the case finally came before the divisional committee, which found that Mr. Sloman had been justified in breaking off negotiations for the purchase of the practice in question, but that he had transgressed the recognised rules of the medical profession in immediately starting to practise in close proximity to the vendor. A resolution was then passed prescribing terms under which Mr. Sloman should either carry out the purchase or continue to practise in Bedford without interfering with the vendor's practice, and to these conditions Mr. Sloman agreed to submit. Four years later the branch committee passed a further resolution strongly condemning the action of Mr. Sloman in remaining and practising in Bedford, and a resolution that this should be sent to all the members of the division. Upon these resolutions and upon the proceedings immediately connected with them the plaintiff based an action in which he asked for a declaration that the resolutions were null and void, and that the passing of them was *ultra vires;* he also claimed damages for libel against Dr. Goldsmith and the Association and for slander against Dr. Butters. The defendants denied that the resolutions were *ultra vires*, and as regards the libel and slander pleaded privilege. After the plaintiff had been called in support of his case and had been cross-examined

[2] THE LANCET, August 23rd, p. 585.
[3] THE LANCET, August 9th, p. 411, and Oct. 18th, p. 1131.

Mr. Justice Rowlatt suggested that the parties might confer with a view to a settlement, which was accordingly done, the terms arrived at being that the resolutions objected to by the plaintiff should be expunged and taxed costs paid to him, together with a sum of £500. In stating the terms of settlement Mr. Hollis Walker, K.C., counsel for the defendants, pointed out that with regard to a condition which Mr. Sloman had accepted, to the effect that he should refrain for three years from treating any of the vendor's patients, it was not suggested that the plaintiff had not loyally fulfilled his undertaking. It should therefore be publicly known that he was entitled to practise on an equal footing with other medical men at Bedford, and to be met by them in consultation without restriction. Mr. Hugo Young, K.C., on behalf of the plaintiff, withdrew any suggestion that the defendants had been actuated by malice other than "legal malice" arising out of the circumstances in which the resolutions had been passed. He also withdrew, on behalf of Mr. Sloman, any imputation made by him to the effect that the British Medical Association could not be trusted to adjudicate fairly upon any matter coming before it.

ASYLUM REPORTS.

Dorset County Asylum (Annual Report for the Year 1912).—The number of patients in residence at the close of 1912 was 941, the highest number in the history of the institution. While two-thirds of the increase are due to a rise in the number of private patients, there has been a very exceptional increase in male county patients. There were admitted 119 cases during the year. The form of mental disorder among the admissions does not materially differ from recent years, there being again a high preponderance of the maniacal type, especially among women. On direct admissions the relative percentage of mania to melancholia among women is as 68 per cent. to 19 per cent., whereas on the male side the figures are 38 per cent. to 34 per cent. Dr. P. W. Macdonald, the medical superintendent, in criticising the Census reports, mentions that he had visited a cottage, and out of the family of seven had had no difficulty in determining that four were unmistakably mentally defective, yet the mother assured him that none were so marked in the Census returns. The admissions for 1912 show a percentage of over 60 with undeniable histories of a predisposition to mental disease. The discharges numbered 80, the percentage of total recoveries on the direct admissions being 38·02. The deaths numbered 70, giving a rate of 7·58 on the average daily number resident.

Staffordshire County Mental Hospital at Stafford (Annual Report for the Year 1912).—The total number of cases under treatment during the year was 1114, the average daily number on the register being 874. The admissions numbered 249, showing an increase of 30 as compared with the preceding year. 132 cases were discharged, of whom 73 had recovered, giving a percentage of recoveries on the direct admissions of 30·93. Nineteen men and 29 women were discharged relieved to the care of friends, and 11 transferred to other asylums. The deaths numbered 113, giving a percentage of 10·14 of the total number in treatment. The chief causes of death were pulmonary tuberculosis (31), cardiovascular degeneration (22), cerebral degeneration (12), heart disease (12), and general paralysis (7).

Staffordshire County Mental Hospital at Burntwood, near Lichfield (Annual Report for the Year 1912).—The average daily number on the registers at this asylum was 914, the total number of cases under treatment having been 1190. There were admitted 265 cases. Ninety-four cases were discharged, and of these 62 were recovered, the percentage of recoveries on the direct admissions being 24·5. The deaths numbered 127, the percentage of deaths on the average daily number being 13·89. Dr. J. B. Spence, the medical superintendent, remarks that the children's wards are overcrowded on both sides. It would appear that Dr. Spence has frequently drawn attention to the necessity for providing proper accommodation for this class of case, but has hitherto been disappointed in the result of his recommendations.

Surrey County Lunatic Asylum at Brookwood (Annual Report for the Year 1912).—The total number of cases under care at this asylum during the year was 1476, the average number resident being 1264. The admissions numbered 232, and of these 206 were direct. A considerable proportion of the cases showed some degree of congenital deficiency underlying their attack of insanity. A history of insane heredity was ascertained in only 20 per cent. of the cases. 145 cases were discharged, and of these 60 were recovered, giving a recovery rate calculated on the admissions, but excluding transfers, of 30·15 per cent. The deaths numbered 63, giving a rate of 4·98 per cent. on the daily average number resident. This is the lowest rate that has ever been recorded in Brookwood Asylum. Post-mortem examinations were held in 82 per cent. of the cases.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

City of Manchester.—Dr. J. Niven's last annual report, like its many predecessors, contains a large amount of valuable information on the prevalence and prevention of disease. The City of Manchester has a population estimated at 724,168, representing 35 persons per acre, and 152,317 families or separate occupiers at the last Census. The annual birth-rate per 1000 of the population in 1912 was 25·09, a figure which, though high relatively to the country as a whole, represents a still further decline in the Manchester rate, and one which has been general throughout the different divisions of the city. There is still, however, a high rate of "natural increase" of births over deaths, the excess amounting to 6455 during the year. The recorded death-rate was 16·18 per 1000, and the corrected rate 17·47, a figure which nearly reaches the low water mark attained in 1910. The greatest improvements in mortality have occurred under the heads of tuberculosis of the lungs and other forms of tuberculosis, diseases of the digestive organs, diarrhœa, and nervous diseases. The mortality from phthisis, 1·53 per 1000, continues the gradual fall which has taken place in the deaths from this disease for the last 20 years at least; that from tuberculous diseases other than phthisis, the mean for which in 1891–1900 was 0·9, and in 1901–11 was 0·61, was reduced in 1912 to 0·54. The infantile death-rate, 122 per 1000 births, was also a low one for Manchester. An analysis of the causes of infantile mortality brings out the high relative incidence of fatal diarrhœa in the first three months of life, and the high proportion also of the deaths which are classed as due to "premature birth" and "atrophy." Diphtheria, Dr. Niven points out, has not shown any improvement in its death-rate in Manchester for the last 40 years, notwithstanding the great amount of scientific work devoted to this disease. In 1912 the number of notified cases was 474, and the case fatality at all ages no less than 20 per cent.; 313 of these cases were admitted to Monsall Hospital, of which 61 were fatal, 25 of the deaths occurring within 48 hours of admission. Tracheotomy was performed on 54 patients, of whom 28 died. Dr. J. Fletcher's report on this hospital contains an interesting statement as to the examination of the throat and nose of scarlet fever patients, which seems to illustrate the extent to which the diphtheria bacillus may be found among the general population of Manchester. A practice has now been made of swabbing the nose and throat of every scarlet fever case on admission and on transference to a convalescent ward. As a result of this investigation about 12 per cent. of the patients were found, on or after admission, to be harbouring the diphtheria bacillus, the nose in 94 per cent. of the cases acting as the nidus. Dr. Niven notes with satisfaction a distinct improvement in the death-rate from whooping-cough, which he attributes mainly to greater care bestowed by mothers on their infants, and partly to the municipal housing administration, which has improved the lighting of houses and the movement of air about them. The cancer death-rate shows an almost steady increase since 1881, and has doubled since that date. He considers that part of this increase is due to improvements in diagnosis, and part to alteration in the age-constitution of the population, but enough remains to make the increase a serious and menacing fact. Attention is drawn in the report to the high attack-rate of enteric fever in Manchester, although the death-rate from this disease has again touched the lowest point so far

recorded. A section of the report, by Dr. Barbara M. Cunningham, gives special consideration to the association of enteric fever with the consumption of mussels, which it is thought, as a result of inquiries, may have conveyed infection in 108 out of the 242 notified cases. The mussels were steamed, or nominally cooked, in at least 52 of these instances. The hospital committee decided to allow a woman, a well-known enteric fever carrier, a sum of money sufficient, along with her old age pension, to keep her from the necessity of taking lodgers to make a living. Puerperal fever notifications in Manchester are proportionately three times as many as in England and Wales generally, but the chief reason is probably the greater activity of the local administration in regard to this disease. The death-rate appears at present to be stationary. Of 124 cases notified in 1912, 88 were admitted to Monsall Hospital, and of these 15 were fatal. The records as to ophthalmia neonatorum were satisfactory; 655 cases came to notice by notification or otherwise, about a third being treated by private medical men and two-thirds at the Royal Eye Hospital. The cornea was involved in 76 instances, of which 64 completely recovered. The two nurses appointed in 1911 for this purpose are stated to have overtaken their work in 1912 in a most efficient manner. Poliomyelitis was notified in 55 cases in 1912, and the results of an instructive examination of these cases by Mr. W. St. C. McClure are included in the report. It is noteworthy that practically no evidence of infectivity could be traced. Two cases occurred in each of three houses; in two houses the cases occurred simultaneously, in the third case after an interval of six days. In the total of 52 houses affected there were 217 persons exposed to infection, 50 of whom were under 5 years of age and 99 under the age of 10 years, and amongst these only one case occurred in which personal infection could be suspected. The cases as a whole were not of a severe type. The development of the large municipal organisations to deal with tuberculosis is naturally a principal feature of the report. Before the schemes which are at present being undertaken were originated Manchester already had substantial hospital provision for tuberculosis: under the corporation and guardians, 559 beds; under the board of the consumption hospital, about 50 beds; between 60 and 70 for surgical operative treatment in charitable institutions; an unknown number for other forms of tuberculosis in charitable institutions and Poor-law hospitals, and a large number of beds in convalescent homes. At the commencement of "sanatorium benefit" this number was increased by 150 beds at the Baguley Sanatorium, and it is evident that when the work of the present year comes to be reviewed a large extension of dispensary and sanatorium work generally will have to be chronicled. The report continues the valuable record of inquiries as to possibilities of personal infection in tuberculosis cases which has been made in previous years. Passing reference may be made to the adoption of the Notification of Births Act in Manchester, after many years of controversy, in 1912; to the large amount of useful work which is here undertaken by health visitors; and to the statistical summaries of the administrative work of the public health department. An outbreak of food poisoning, attributed to infection of meat by the Gärtner bacillus, occurred in October in Openshaw, 163 persons being attacked, three with fatal results. The meat was obtained from different sources, and inquiries showed that an infection, probably present in certain portions of pig's meat, was extended to other meat foods as a result of the conditions in which meat was prepared at the shop in question.

Borough of Halifax.—In this borough the greater number of houses are not provided with water-closets, night soil being dealt with on what is known as the "Goux" system. The Goux tubs are renewed at periods varying from three to ten days according to circumstances, being washed on each occasion after they are emptied and partially filled with absorbent material before being returned to the closets. The system involves the use of 21 horses and vans and 31 men; it is not now being extended to any houses where a sewer and water-supply are available. Although this method is not one which can be looked at with favour at the present day, and is probably far from economic, it does not seem to have conduced to the same maintenance of enteric fever and infantile diarrhœa that is frequently met with in other towns served by conservancy systems. In 1912 the notified cases of enteric fever, in a population of about 102,000, were only 35, and the infant mortality rate was as low as 81 per 1000 births. Halifax is supplied with water from gathering grounds of a moorland character, the water of which is liable to contain an excessive amount of peaty acids, and hence to possess a solvent action upon lead. These supplies are treated to remove acidity with satisfactory results, though Dr. J. T. Neech suggests that the addition of lime, the neutralising agent employed, should be regulated more closely. Examples of the danger of lead pipes were furnished in 1912 in several instances where the supply, obtained from local wells, was brought to the houses by lead pipes. One fatal case of lead poisoning occurred, and in 20 houses a number of other cases came under notice. The report gives considerable attention to the examination of food and drugs during the year, and draws special attention to the liability of olive oil to be adulterated, and to the objections to bleaching and other means of treating flour and bread. In regard to flour "improvers," Dr. Neech observes that "at the best it is no satisfaction to the ordinary buyer of bread to learn that preparations are sold to enable bakers to get 10 or 15 more loaves per sack of flour than before, the obvious result being that the resulting loaves have each less nutriment in them."

Borough of Derby.—Dr. A. E. Brindley estimates that about 75 per cent. of the births in Derby are attended by midwives, which would represent about 2200 births last year. The fact that the midwife sent for medical aid in as many as 204 of these cases seems to be evidence that the requirements of the Central Midwives Board are strictly carried out in this town. The report gives special attention to the deplorably insanitary conditions met with in certain houses which have been turned into "furnished lodgings," usually by non-resident proprietors. There is no water-supply usually within the house on any floor, the bedding is of a filthy character, the staircases are invariably dark, there is no provision for food storage, no cooking conveniences or appliances are provided, nor is lighting or fuel supplied by the keeper of the house. Dr. Brindley's claim for special powers being obtained by legislation to deal with this class of house will be supported by many of those who have experience of the conditions often found in "furnished rooms." They are far worse in most respects than common lodging-houses, and Dr. Brindley suggests that they are multiplied whenever steps are taken to close houses of low rental. In such cases, he argues, the evil of allowing old insanitary houses without through ventilation to stand may be the lesser of the two. He considers that the houses in question should be differentiated from the much larger class of working-class houses in which lodgers are received and maintained under reasonably good conditions which are capable of being regulated under by-laws. For the "furnished rooms" the remedy which he suggests is annual licensing in the same way as with common lodging-houses. The establishment of a tuberculosis dispensary in connexion with the health office in February, 1912, was one of the chief sanitary events of the year, the dispensary representing the centre of the whole scheme for dealing with this disease. Negotiations for the acquisition of more suitable premises appear to have caused some difficulty, and pending their completion the staff of the public health department has had to carry on its ordinary work under conditions of considerable difficulty owing to the use of their offices both for school clinics and tuberculosis dispensary work.

REPORTS OF SCHOOL MEDICAL OFFICERS.

County of Essex.—The fourth annual report by Dr. H. W. Sinclair begins with a preface giving a useful view of the relationship of Essex with other counties, and of its population, area, and method of administration. An epidemic of measles is described which progressed steadily across eight miles of a country district despite school closure. The disease spread from house to house and from hamlet to hamlet, and six months were occupied in traversing the eight miles of country. From May to December, 1912, 1034 elementary school children received dental treatment at 16 centres, and in the Woodford district, where a dental clinic has been established three years, a 10 per cent. improvement in the condition of teeth was found on inspection. There are included in the report three special reports, on (1) Treatment of Defective Vision, by Mr. E. M. Wyche (including

an illustration of a portable lamp for eye work invented by Mr. Wyche); (2) Deformities and Malformations, by Dr. E. B. Smith, who estimates that there are 980 children (or 1·4 per cent.) so afflicted among the 70,000 on the registers; and (3) on "Nervous" Children, by Mr. H. Emlyn Jones, giving the results of an experiment on mental fatigue and pleading for special educational facilities for the "nervous" group such as are provided for the physically and mentally defective. Of this latter class 50 per cent. of the cases in the county are now educationally provided for.

County of Berkshire.—Dr. Gerard C. Taylor's report notes the marked difference in the number of cases diagnosed as tuberculosis of the lung from year to year. The figures are: 1908, 0·127 per cent.; 1909, 0·154 per cent.; 1910, 0·327 per cent.; 1911, 1·07 per cent.; and 1912, 0·55 per cent. The education committee have as yet made no provision for treatment, but have appointed two school nurses, and two voluntary dental clinics are in operation.

Hertfordshire County Council.—Mr. F. E. Fremantle deals largely with the question of the treatment of defects, which he holds can be best dealt with in a rural area by a comprehensive nursing system. The Herts county council pays a subvention of £300 a year to the county nursing association, and receives in return many valuable services which are fully available for about one-half of the area. To supply the deficiency the report suggests an extension of the nursing service, which it describes as "the only reasonable alternative to a specific system of treatment." The plan here indicated has one great merit, for "it is only the district nurse who invades the individual home, whether as district nurse or midwife, tuberculosis nurse, school nurse, or health visitor." But when the report calls for the provision of treatment necessary through the Poor-law guardians and the "development in connexion with the infirmaries of out-patient departments comparable to those of the voluntary hospitals," and follows up the suggestion by the statement that there "should be one State Medical Service ..... with one municipal hospital ..... in every town," it appears that Mr. Fremantle is allowing a passion for a "unified system" to cause him to overlook the practical difficulties. If the education authority took over all the functions of the guardians relating to children and became in theory what it is fast becoming in fact, a child authority, a unified system of a kind would be called into existence and would fit the everyday facts and difficulties instead of being imposed upon them. The report shows that of 742 defective children in the city of St. Albans 336 were treated, and of 522 defective in the St. Albans rural district only 202 were treated; in Watford (urban district), among 920 cases notified as defective, only 335 are known to have complied with the suggestion for treatment. These results are quoted as examples of "what may be done with the help of our system," but are not very likely to encourage other educational authorities. The report however, proposes the equipment of an old London horse 'bus as a travelling dental caravan at a cost, including equipment, of under £100, and utilising the services of a full-time dentist at £300 a year, who could spend a week or less in each village to overtake arrears, and suggests the provision of this travelling clinic as a suitable object for philanthropy.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns, with populations exceeding 50,000 persons at the last Census and whose aggregate population at the middle of this year is estimated at 17,852,766 persons, 8646 births and 4671 deaths were registered during the week ended Saturday, Oct. 18th. The annual rate of mortality in these towns, which had been 14·4, 13·6, and 14·3 per 1000 in the three preceding weeks, declined to 13·6 per 1000 in the week under notice. During the thirteen weeks of last quarter the mean annual death-rate in these towns averaged 12·7, against a corresponding rate of 11·8 per 1000 in the Metropolis. Among the several towns the death-rate last week ranged from 5·4 in Wimbledon, 5·6 in Bournemouth, 5·9 in Southend-on-Sea, 6·7 in Gillingham, and 7·0 in Enfield and in Wakefield, to 19·5 in Walsall, 19·7 in Barnsley, 19·8 in Sunderland, 24·1 in Tynemouth, and 24·3 in Oldham.

The 4671 deaths from all causes were 217 fewer than the number in the previous week, and included 743 which were referred to the principal epidemic diseases, against 866 and 925 in the two preceding weeks. Of these 743 deaths, 601 resulted from infantile diarrhœal diseases, 49 from diphtheria, 32 from whooping-cough, 25 from measles, 20 from enteric fever, and 16 from scarlet fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 2·2, against 2·5 and 2·7 per 1000 in the two preceding weeks. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had been 927, 730, and 769 in the three preceding weeks, declined to 601 last week; of this number 157 were recorded in London, 34 in Birmingham, 30 in Liverpool, 20 in Manchester, 18 in Hull, 17 in Sheffield, 16 in Sunderland, and 15 in West Ham. The deaths referred to diphtheria, which had been 38, 43, and 44 in the three preceding weeks, further rose to 49 last week, and included 12 in London, 3 in Portsmouth, 3 in Birmingham, and 2 each in Northampton, Plymouth, Bolton, Barrow-in-Furness, Cardiff, and Rhondda. The fatal cases of whooping-cough, which had been 49, 32, and 39 in the three preceding weeks, fell to 32 last week; 8 deaths were registered in London, 3 in Birmingham, 3 in Liverpool, and 2 in Manchester. The deaths attributed to measles, which had been 31, 28, and 26 in the three preceding weeks, were 25 last week, and included 5 in London, 3 in Oldham, and 2 each in Stockport, Liverpool, Blackpool, Bradford, and Dewsbury. The deaths referred to enteric fever, which had steadily increased from 10 to 24 in the five preceding weeks, declined to 20 last week; 5 deaths occurred in London and 2 each in Stoke-on-Trent, Dudley, Leeds, and Hull. The fatal cases of scarlet fever, which had been 19, 14, and 23 in the three preceding weeks, fell to 16 last week, of which number 3 were recorded in London, 3 in Manchester, and 3 in Sunderland.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had steadily risen from 2112 to 3021 in the six preceding weeks, had further increased to 3247 on Saturday last; 575 new cases were admitted during the week, against 508, 498, and 484 in the three preceding weeks. These hospitals also contained on Saturday last 1112 cases of diphtheria, 180 of whooping-cough, 68 of enteric fever, and 65 of measles, but not one of small-pox. The 1224 deaths from all causes in London were 5 fewer than the number in the previous week, and were equal to an annual death-rate of 14·1 per 1000. The deaths referred to diseases of the respiratory system, which had been 134, 123, and 176 in the three preceding weeks, fell to 151 last week, and were no fewer than 175 below the number recorded in the corresponding week of last year.

Of the 4671 deaths from all causes in the 96 towns, 159 were attributed to different forms of violence and 334 were the subject of coroners' inquests. The causes of 25, or 0·5 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Sheffield, Leeds, Bristol, West Ham, Bradford, Hull, Newcastle-on-Tyne, Nottingham, and in 70 other smaller towns. Of the 25 uncertified causes of death last week, 4 were registered in Birmingham, 3 in London, 2 in Liverpool, and 2 in St. Helens.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns, with an aggregate population estimated at 2,259,600 persons at the middle of this year, 1106 births and 600 deaths were registered during the week ended Saturday, Oct. 18th. The annual rate of mortality in these towns, which had been 15·1, 14·5, and 14·7 per 1000 in the three preceding weeks, declined to 13·9 per 1000 in the week under notice. During the thirteen weeks of last quarter the mean annual death-rate in these towns averaged 14·3, against 12·7 per 1000 in the 96 large English towns. Among the several Scotch towns the death-rate last week ranged from 7·3 in Clydebank, 7·6 in Ayr, and 8·9 in Motherwell, to 16·5 in Kilmarnock, 17·4 in Greenock, and 18·3 in Paisley.

The 600 deaths from all causes were 38 fewer than the number in the previous week, and included 69 which were referred to the principal epidemic diseases, against numbers declining from 126 to 81 in the five preceding weeks.

Of these 69 deaths, 29 resulted from infantile diarrhœal diseases, 14 from measles, 13 from scarlet fever, 8 from diphtheria, 3 from enteric fever, and 2 from whooping-cough, but not one from small-pox. These 69 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·6, against 2·2 per 1000 in the 96 large English towns. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had steadily declined from 96 to 43 in the five preceding weeks, further fell to 29 last week; of this number, 11 were recorded in Glasgow, 7 in Dundee, 3 in Aberdeen, 2 in Edinburgh, and 2 in Motherwell. The deaths referred to measles, which had been 10, 8, and 14 in the three preceding weeks, were again 14 last week, and included 9 in Glasgow and 2 in Edinburgh. The fatal cases of scarlet fever, which had been 5, 7, and 6 in the three preceding weeks, rose to 13 last week; 4 deaths were registered in Aberdeen and 3 in Glasgow. The deaths attributed to diphtheria, which had been 10, 14, and 13 in the three preceding weeks, declined to 8 last week, and included 3 in Glasgow and 2 in Aberdeen. The 3 deaths referred to enteric fever were equal to the average in the four preceding weeks, and were recorded in Glasgow, Dundee, and Clydebank respectively. The 2 fatal cases of whooping-cough occurred in Glasgow.

The deaths referred to diseases of the respiratory system, which had increased from 63 to 84 in the four preceding weeks, fell to 80 last week; 26 deaths were attributed to different forms of violence, against 27 and 23 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,199,180 persons at the middle of this year, 599 births and 367 deaths were registered during the week ended Saturday, Oct. 18th. The annual rate of mortality in these towns, which had been 21·0, 18·0, and 17·1 in the three preceding weeks, further fell to 16·0 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these towns averaged 18·2 per 1000; in the 96 large English towns the corresponding rate did not exceed 12·7, while in the 16 Scotch towns it was equal to 14·3 per 1000. The annual death-rate last week was equal to 17·7 in Dublin (against 14·1 in London and 13·9 in Glasgow), 14·6 in Belfast, 13·6 in Cork, 14·0 in Londonderry, 8·1 in Limerick, and 3·8 in Waterford, while in the 21 remaining smaller towns the mean annual death-rate was 19·3 per 1000.

The 367 deaths from all causes were 27 fewer than the number in the previous week, and included 61 which were referred to the principal epidemic diseases, against numbers steadily declining from 132 to 68 in the five preceding weeks. Of these 61 deaths, 48 resulted from infantile diarrhœal diseases, 4 from scarlet fever, 3 from measles, 3 from whooping-cough, and 3 from diphtheria, but not one from enteric fever or from small-pox. The mean annual death-rate from these diseases last week was equal to 2·7 per 1000; in the 96 large English towns the corresponding rate was 2·2, while in the 16 Scotch towns it did not exceed 1·6 per 1000. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had steadily declined from 111 to 55 in the five preceding weeks, further fell to 48 last week; of this number 23 occurred in Dublin, 9 in Belfast, and 4 in Cork. The 4 deaths referred to scarlet fever, comprising 3 in Belfast and 1 in Limerick, were equal to the average in the five preceding weeks. Of the 3 fatal cases of measles, 2 were recorded in Galway and 1 in Dublin. The 3 deaths from whooping-cough were slightly below the average in recent weeks, and comprised 2 in Galway and 1 in Dublin. The 3 deaths referred to diphtheria were equal to the average in the four preceding weeks, and included 2 in Dublin and 1 in Belfast.

The deaths referred to diseases of the respiratory system, which had been 60, 34, and 54 in the three preceding weeks, fell to 48 in the week under notice. Of the 367 deaths from all causes, 89, or 24 per cent., occurred in public institutions, and 5 resulted from various forms of violence. The causes of 18, or 4·9 per cent. of the total deaths, were not certified either by a registered medical practitioner or by a coroner after inquest; in the 96 large English towns the proportion of uncertified causes of death last week did not exceed 0·5 per cent.

VITAL STATISTICS OF LONDON DURING SEPTEMBER, 1913.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to an annual rate of 7·7 per 1000 of the population, estimated at 4,518,191 persons in the middle of the year; in the three preceding months the rates were 5·4, 6·6, and 5·4 per 1000 respectively. The lowest rates last month were recorded in Kensington, Hammersmith, the City of Westminster, Hampstead, Stoke Newington, Wandsworth, and Lewisham; and the highest rates in Shoreditch, Bethnal Green, Poplar, Southwark, Bermondsey, and Deptford. The prevalence of scarlet fever showed a considerable increase over that recorded in other recent months; this disease was proportionally most prevalent in Chelsea, Holborn, the City of London, Poplar, Southwark, Bermondsey, Camberwell, and Deptford. The Metropolitan Asylums Hospitals contained 2552 scarlet fever patients at the end of last month, against 2093 at the end of each of the two preceding months; the weekly admissions averaged 402, against 312 and 258 in the two preceding months. Diphtheria was more prevalent during September than in any previous month of this year; the greatest proportional prevalence of this disease last month was recorded in St. Pancras, Shoreditch, Bethnal Green, Battersea, and Deptford. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 886 and 798 at the end of the two preceding months, had risen again to 909 at the end of last month; the weekly admissions averaged 147, against 128 and 99 in the two preceding months. Enteric fever also was more prevalent than in any preceding month of the year; the greatest proportional prevalence of this disease was recorded in Kensington, Finsbury, Stepney, Southwark, and Lewisham. There were 56 enteric fever patients under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 50 and 37 at the end of the two preceding months; the weekly admissions averaged 11, against 10 and 6 in the two preceding months. Erysipelas was proportionally most prevalent in Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, and Deptford. The 27 cases of puerperal fever notified during the month included 3 in Kensington, 3 in Stepney, 3 in Southwark, and 2 each in Paddington, Hammersmith, Bethnal Green, Lambeth, and Greenwich. The 6 cases of cerebro-spinal meningitis belonged respectively to Fulham, Stoke Newington, Stepney, Lambeth, Battersea, and Wandsworth; and the 27 cases of poliomyelitis included 8 in Stepney, 5 in Islington, and 2 each in Kensington, Stoke Newington, Shoreditch, and Lewisham.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the several boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex- and age-constitution of the populations of the several boroughs. During the four weeks ending Sept. 27th, 4610 deaths of London residents were registered, equal to an annual rate of 13·3 per 1000; in the three preceding months the rates had been 11·1, 10·6, and 11·8 per 1000 respectively. The death-rates last month ranged from 7·9 in Hampstead, 8·5 in Lewisham, 10·3 in Stoke Newington and in Wandsworth, 11·1 in Chelsea and in the City of London, and 11·2 in Woolwich, to 16·3 in Finsbury, 16·7 in Stepney, 16·8 in Bethnal Green, 18·3 in Southwark, 19·6 in Bermondsey, and 22·5 in Shoreditch. The 4610 deaths from all causes included 927 which were referred to the principal infectious diseases; of these, 15 resulted from measles, 9 from scarlet fever, 25 from diphtheria, 30 from whooping-cough, 10 from enteric fever, and 838 from diarrhœa and enteritis among children under two years of age. No death from any of these diseases was recorded last month in the City of London; among the metropolitan boroughs they caused the lowest death-rates in the City of Westminster, Hampstead, St. Marylebone, St. Pancras, Stoke Newington, and Lewisham; and the highest rates in Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, and Bermondsey. The 15 fatal cases of measles were 34 fewer than the corrected average

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING SEPTEMBER, 1913.

* Including membranous croup. † The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard.

number in the corresponding period of the five preceding years, and included 4 in Camberwell, 3 in Bermondsey, and 2 in Lambeth. The 9 deaths from scarlet fever were 10 below the corrected average, and included 2 in Hammersmith, and 2 in St. Marylebone. The 25 fatal cases of diphtheria showed a decline of 16 from the corrected average number, and included 4 in Poplar, 3 in Islington, 3 in Bermondsey, 2 in Southwark, and 2 in Lewisham. The 30 deaths from whooping-cough were 21 below the corrected average, and included 5 in Islington, 3 in Finsbury, 3 in Stepney, 2 in Hackney, 2 in Poplar, and 2 in Camberwell. The 10 deaths from enteric fever were equal to one-half the corrected average number, and included 2 in Paddington and 2 in Stepney. The mortality from diarrhœa and enteritis among children under 2 years of age was proportionally greatest in Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, Bermondsey, and Battersea. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases, excluding diarrhœa, was 50·6 per cent. below the average.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointment has been notified:—Staff-Surgeon: A. Woollcombe to the *Fearless*, temporary, to date Oct. 18th.

ROYAL ARMY MEDICAL CORPS.

Major Norman Faichnie to be Lieutenant-Colonel, vice O. R. A. Julian, C.M.G., supernumerary (dated Oct. 13th, 1913).

Captain Charles V. B. Stanley retires, receiving a gratuity (dated Oct. 22nd, 1913).

Colonel R. J. Geddes, D.S.O., has taken up duty as Assistant Director of Medical Services at Military Headquarters, Devonport District. Colonel F. J. Jencken, Assistant Director of Medical Services to the Colchester District, has been granted leave of absence.

Lieutenant-Colonel M. O'D. Braddell on transfer to the Home Establishment, tour expired from India, has been appointed to the Irish Command from Oct. 26th for duty in the Cork District. Lieutenant-Colonel A. T. I. Lilly has been transferred from the Military Hospital at Belgaum Cantonment and appointed to hold charge of the Military Hospital at Colaba, Bombay. Lieutenant-Colonel J. Will, Deputy Assistant Director of Medical Services to the Northumbrian Division at Richmond, has been selected for increased rate of pay under Article 358 of the Royal Warrant for Pay and Promotion. Brevet-Colonel C. H. Melville has been appointed to hold charge of the Military Hospital at Tidworth, Salisbury Plain District. Lieutenant-Colonel J. W. Bullen has been transferred from India to the Home Establishment on the expiration of leave of absence. Lieutenant-Colonel J. Givin has been appointed Senior Medical Officer on board the transport s.s. *Rewa*, which left Bombay for Southamptom with time-expired troops on Oct. 10th.

Major St John B. Killery has been granted six months' general leave of absence home from India. Major W. A. Ward has been transferred from the London District to the Military Hospital at Bulford Camp Salisbury Plain. Major W. P. Gwynn has been transferred from India to the Home Establishment at the termination of his tour of duty. Major N. J. C. Rutherford has been selected for appointment as Specialist Sanitary Officer to the Cork District in succession to Major J. Dorgan, who has embarked for a tour of service at Hong-Kong. Major B. Watts has been appointed for duty in medical charge of troops on board the transport s.s. *Rewa*. An exchange has been approved by the Director-General between Major J. W. Houghton and Major J. S. Bostock, serving at Aldershot and Agra Cantonment respectively. Major E. Bennett has taken up duty at Poona Cantonment. Major J. A. Hennessy has been selected to hold charge of the Military Hospital at Ahmednagar Cantonment. Major H. A. Davidson has embarked for a tour of service in the Straits Settlements, and on arrival will be appointed to the Military Hospital at Singapore. Major J. V. Forrest has been appointed to the London District for duty in the Medical Division at the War Office. Major J. C. Kennedy has been appointed Specialist in Bacteriology at the Royal Army Medical College, Millbank.

Captain L. A. A. Andrewes has been selected for appointment as Specialist in Dermatology and Venereal Diseases at the Military Hospital, York, with effect from Nov. 1st, in succession to Captain T. E. Harty, who has embarked for a tour of service in the Sierra Leone Protectorate. Captain D. T. MacCarthy has been granted an extension of Indian tour of service for one year. Captain J. Du P. Langrishe has been appointed to the Cork District for duty. The services of Captain D. P. Watson have been placed at the disposal of the Colonial Office in connexion with the prevention of sleeping sickness in the Nyasaland Protectorate. Captain J. B. Meldon has been placed under orders to embark for a tour of service with the Northern Army in India, and on arrival will be appointed to the First (Peshawar) Division for duty. Captain P. C. Field has arrived home on general leave of absence from the Military Hospital at Alexandria. Captain B. Johnson has been appointed to the Irish Command for a tour of duty. Captain G. F. Rudkin has been transferred from India to the Home Establishment at the termination of leave of absence. Captain R. P. Lewis has taken up duty at the Military Hospital, Aldershot. Captain S. S. Dykes has been transferred from the Military Hospital at Dinapore to Dum Dum. Captain W. J. Tobin has been granted six months' general leave of absence home from India. Captain M. Leckie has arrived home on general leave of absence from duty with the Egyptian Army. Captain W. I. Thompson has been appointed to the Aldershot Command for a tour of duty. Captain C. A. J. A. Balck, specialist in physical training at the Military Hospital, Curragh Camp, has qualified as a First-class Interpreter in the French Language under War Office Regulations. Captain G. Ormrod has taken up duty at the Military Hospital, Aldershot. Captain A. H. Hayes has been placed under orders to embark for a tour of service with the Northern Army in India, and on arrival will be appointed for duty in the Third (Lahore) Division. Captain H. G. Robertson has arrived home on general leave of absence from the Military Hospital at Malta. Captain G. P. A. Bracken has been appointed to the Northern Command for a tour of duty. Captain W. P. Purdon has taken up duty on the Home Establishment on transfer from India at the termination of leave of absence. Captain H. G. Sherren has taken up duty in the London District. Captain C. T. V. Benson has been transferred from the Military Hospital at Calicut to Bangalore Cantonment. Captain V. T. Carruthers has been appointed to the Military Hospital at Norwich.

Lieutenant O. W. J. Wynne has been placed under orders to embark at Southampton for a tour of duty with the Southern Army in India, and on arrival will be appointed to the Eighth (Lucknow) Division for duty. Lieutenant J. H. C. Greene has been seconded for service under the Colonial Service. Lieutenant H. S. Blackmore has been appointed to hold medical charge at St. John's Wood Barracks, London. Lieutenant J. E. M. Elliott has taken up duty at the Military Hospital, Winchester. Lieutenant D. W. Bruce has been appointed to hold charge of the Ewshott Reception Hospital at Aldershot. Lieutenant P. A. With has taken up duty at the Military Hospital, Curragh Camp. Lieutenant W. F. Christie has embarked for a tour of duty in the Straits Settlements. Lieutenant W. Stewart has arrived in India for a tour of duty. Lieutenant N. T. Whitehead and Lieutenant A. L. Urquhart have joined the Royal Army Medical College for a course of instruction in Military Hygiene and Sanitation. The following officers have been placed under orders to embark at Southampton for a tour of duty in India: Lieutenants E. T. Vivian, W. B. Laird, F. R. B. Skrimshire, E. B. Allnut, H. C. Todd, E. C. Deane, I. R. Hudlestone, W. Macnaughton, D. T. M. Large, W. W. Pratt, M. Burnett, C. J. Blaikie, and S. J. Barry.

INDIAN MEDICAL SERVICE.

The King has approved of the promotion of the following officers of the Indian Medical Service:—

Lieutenant-Colonel to be Colonel (dated June 30th, 1913): Robert Robertson.

Majors to be Lieutenant-Colonels (dated July 29th, 1913): Cecil Charles Stuart Barry, Jay Gould, John Mulvany, Henry Burden, C.I.E., Charles Harford Bowle-Evans, Hugh Bennett, Alfred Eugene Berry.

Captains to be Majors (dated July 29th, 1913): Alfred Ernest John Lister, Thomas Samuel Beauchamp Williams, John Edmund Clements, Ernest Bisset, Alexander William Overbeck-Wright, David Munro, Robert Markham Carter, Dodington George Richard Shurton Baker, Jasper Robert Joly Tyrrell, Thomas Henry Gloster, James Henry Horton, D.S.O., William Adolphus Justice.

Lieutenants to be Captains (dated July 30th, 1913): Phirozshah Byramji Bharucha, Richard William George Hingston, John Bailey Tackaberry, Charles Newton-Davis, Reginald Charles Clifford, Clive Newcomb, Henry Edward Shortt, Latafat Husain Khan, Robert de Stretton Berkeley Herrick, Hargobind Lal Batra, Murray Purvis, Duncan McNab Taylor.

The King has also approved the retirement of Colonel Charles Fancourt Willis, C.B. (dated Oct. 1st, 1913).

Lieutenant-Colonel R. H. Castor has been granted six months' extension of leave of absence home from India on medical certificate. Lieutenant-Colonel W. E. Jennings has taken up duty under the Government of India. The services of Lieutenant-Colonel D. M. Davidson have been replaced at the disposal of the Government of the Punjab. Lieutenant-Colonel G. B. Irvine has been granted combined leave of absence home from India for one year.

Major H. B. Foster, on return to India from leave of absence home, has been appointed to officiate as Police Surgeon at Calcutta during the absence on combined leave of Major O. St. John Moses. Major A. E. J. Lister has been selected for appointment as Professor of Physiology on the staff of the King George V. Medical College at Lucknow. Major W. Lapsley has been transferred from Bahraich to Gonda and appointed Civil Surgeon. Major G. Y. C. Hunter has been granted an extension of leave of absence for six months home from India on medical certificate. Major J. H. Leicester has been transferred from Behar and Orissa and appointed to officiate as Professor of Midwifery at the Government Medical College, Calcutta, during the absence on leave of Lieutenant-Colonel C. R. Green. Major W. A. Justice has been granted three months' privilege leave of absence.

Captain F. E. Wilson has arrived home on leave of absence from India. The services of Captain S. J. Bhathena have been replaced at the disposal of H.E. the Commander-in-Chief in India by the Home Department. Captain J. M. Skinner has been appointed to officiate as Fourth Physician at the Government Medical College, Madras. The services of Captain A. W. Howlett have been replaced at the disposal of H.E. the Commander-in-Chief for transfer to the Royal Army Medical Corps. Captain J. L. Lunham has been granted an extension of leave of absence home from India. Captain V. B. Nesfield, chemical examiner and Government analyst to the United Provinces, has been appointed to officiate as Civil Surgeon at Banda. The services of Captain R. S. Kennedy have been replaced at the disposal of H.E. the Commander-in-Chief in India. Captain J. A. A. Kernahan has been selected for appointment as Specialist in the Prevention of Disease and placed in charge of the Bacteriological Research Laboratory at Shillong. Captain R. D. Willcocks has been granted an extension of leave of absence home from India for a further six months. Captain J. F. Boyd has taken up duty in connexion with plague prevention in the United Provinces of Agra and Oudh. The services of Captain H. R. Dutton have been placed at the disposal of the Government of Bengal Presidency.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant John C. Hall to be Captain (dated Sept. 30th 1913).

The undermentioned Lieutenants are confirmed in their rank:—Douglas R. King, Gavin Young, Allan D. Fraser, David Mackie, James J. Finlay, Robert G. McElney, Thomas McClurkin, Maurice P. Inglis, Thomas W. E. Elliott, and William A. Lethem.

Lieutenant Donald J. Armour, from the Royal Army Medical Corps (Territorial Force), to be Lieutenant (dated Oct. 22nd, 1913).

TERRITORIAL FORCE.

Royal Army Medical Corps.

2nd Wessex Field Ambulance, Royal Army Medical Corps: Lieutenant David Macnair to be Captain (dated June 3rd, 1913).

3rd Wessex Field Ambulance, Royal Army Medical Corps: Edgar Curnow Plummer to be Lieutenant (dated Sept. 5th, 1913).

South Wales Mounted Brigade Field Ambulance, Royal Army Medical Corps: Captain John Griffiths to be Major (dated May 13th, 1913).

For attachment to Units other than Medical Units.—To be Lieutenants: Douglas Edward Finlay (dated Sept. 1st, 1913) and Harry Winstanley Shadwell (dated March 11th, 1913).

TERRITORIAL FORCE RESERVE.

Royal Army Medical Corps.

Captain William Henry Rowell, from the Notts and Derby Mounted Brigade Field Ambulance, Royal Army Medical Corps, to be Captain (dated Oct. 22nd, 1913).

THE MILITARY SURGEON.

In the *Military Surgeon* (Chicago) for September Fleet-Surgeon Charles N. Fiske, U.S.N., discusses the duties of the principal medical officer of a fleet in preparation for battle. In the United States service this officer is termed the fleet-surgeon; his duties are not comprehensively laid down, but "an officer's position and responsibilities are largely what he makes them." The executive officers of that navy are more and more appreciating the military importance of the work of the medical department, and are more ready to accept advice than are officials in civil life. Still, it is important to keep before them histories of campaigns whose success or failure has resulted from the handling of epidemics or the due evacuation of sick and wounded. By conference with the other medical officers the principal medical officer should arrange in his fleet common schemes for dealing with the wounded during action, treatment of their wounds, and classification of the severity of their injuries. He must also settle who are to keep records of the wounded and of the dead, who besides the surgeons shall give them opiates, who shall affix the diagnosis and identification label, &c. This uniform classification of injuries is of great importance, for when the battle is over and the hospital ship has returned to the fleet from her battle station, 50 or 100 miles away, she can only take a certain number of cases, and a uniform classification of injuries in reports to the flagship allows the admiral to distribute her benefits among the ships in proportion to the damages their men have suffered. Fleet-Surgeon Fiske emphasises the importance to all medical officers of a study of the occurrences in former battles and engagements, that nothing may take them by surprise, and so their equanimity shall improve the confidence of the men and prevent panic. Captain H. W. Jones, Medical Corps, U.S. Army, has been examining old recruiting books in a Southern State, and concludes that the recruits of 1867–8, and especially of 1875–9, were bigger and heavier than those now enlisting. Surgeon D. V. Carpenter, U.S.N., gives an interesting account of the work done by the Egyptian Red Crescent hospital ship in the recent war, when she would carry on one trip perhaps 2000 refugees and 400 wounded soldiers from Salonica to Smyrna. The common diseases were small-pox, dysentery, typhoid fever, and pneumonia.

ARCHIV FÜR SCHIFFS- UND TROPEN-HYGIENE.

In the August issue of this publication Dr. Arthur Scherschmidt says that he has been giving salvarsan injections for yaws, and has been gradually reducing the volume of the injection till he now dissolves 0·45 grm. neosalvarsan in only 10 c.c. of water, and 0·6 grm. salvarsan in 10 c.c. freshly distilled water to which 23 drops of caustic potash solution are added to produce a perfectly clear liquid. This he injects with a 10 c.c. syringe and a very fine needle, and the operation is, of course, much simplified. It needs no longer to be done in hospital, and the vein is much more easily found—all which greatly helps the surgeon working in the tropics. No ill-effects whatever have followed these injections.

NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund held on Oct. 14th, Surgeon-General Arthur W. May, C.B., in the chair, the sum of £45 was distributed among the several applicants.

MEDICAL PRACTICE UNDER THE INSURANCE ACT.

(BY OUR SPECIAL COMMISSIONER.)

(*Continued from p. 1150.*)

XXIV.—NOTTINGHAM: THE PANEL DOCTORS AND THE WOMEN WORKERS.

LITTLE or nothing was done at Nottingham to resist the National Insurance Act. From the first it was felt that a certain number of practitioners would gladly join the panel. The entire arrangement was so evidently to their advantage that it would not be in human nature for them to resist, and it would be incumbent upon others to follow suit. This is a good example of the reason why there was so much difference of opinion about the Act—it works in various localities in various ways; in one place it is a material benefit, in another it inflicts social and financial injury upon the practitioner. At Nottingham, on the whole, the Act is proving advantageous financially to the general practitioner, and some 95 per cent. of them have gone on the panel. It is quite certain that the medical profession there have no desire whatever to see the Act abolished. Yet I have come across some Nottingham medical men who consider that they have lost, and lost in pocket by the Act. Their complaints are similar to those recorded in other industrial towns and districts. Prosperous business men have sons and daughters who are beginning to work and who only earn small salaries, and therefore are insured persons. Formerly their parents paid full fees for them to the family medical adviser. This substantial class of private practice has disappeared. Then here also there are certain classes of insured persons who demand too much from contract practice. Perhaps something more like a resistance would have been attempted at Nottingham if the quarter of a million which it was suggested would be raised to constitute a strike fund had been forthcoming. On several occasions conversation has arisen on this subject during my inquiries, and wonder was manifested that so little money was subscribed for this purpose. The opinion generally expressed is that the blame must be generally distributed, as each individual relied on others to give and thus hardly anyone subscribed. Had the result of the appeal to the medical profession for money been foreseen a properly organised canvass, however late in the day, might have been started, and a very large amount of money could have been obtained. This, at any rate, is the opinion I have formed after discussing the matter now in many different cities and localities.

It should be observed that, if the Nottingham practitioners were not zealous in their opposition to the Act, it was not because they were lacking in the spirit of organisation. On the contrary, a Public Medical Service is established. It is working now, and deals with uninsured persons whose income does not exceed £2 a week. It was started before there was any question of the Insurance Act, as a check on the abuse arising in the Friendly Societies and Medical Aid Associations. The Nottingham Division of the British Medical Association also felt it was necessary to take measures in regard to the families of persons who were members of benefit societies, as to-day it is necessary in regard to the families of insured persons. Then there was a Town Medical Aid organised by trustees. It was self-supporting and approved by the medical profession, though some exception was taken to the arrangements for the selection of the medical staff. Now this body has amalgamated with the Public Medical Service. The special list of medical attendants is abolished, the policy of the open door is introduced, and the patients have a very large choice of medical advisers.

A Popular Panel.

The rule of the Public Medical Service is that all members who are at work or who are more than 16½ years old must pay 2*d.* a week, all children pay 1½*d.* a week, but no family pays more than 6*d.* a week for the children, however numerous they may be. There is a certain elasticity allowed. The management, or central committee, as it is called, may arrange other terms to meet necessitous or special cases. Thus it is proposed to provide medical attendance for all persons outside the Act who are not earning more than £2 a week. Here it must be noticed a strict wage limit is observed. There are 56 medical men on a list from which members of the Public Medical Service can choose their attendant. On the panel and at the service of insured persons there are 98 medical men. Apart from the consultants, specialists, and the hospital staff, there remain, I believe, only four general practitioners who are not on the Nottingham panel. These in themselves are eloquent figures. The number of insured persons is 95,000, and there are about 9000 who as yet have not selected a medical attendant. Unlike many other towns which I have visited on this tour of inspection, the Nottingham Insurance Committee has done nothing, and does not seem inclined to do anything, in regard to the unallotted insured persons. The clerk of the Nottingham Insurance Committee maintained that no Insurance Committee in the kingdom had a sufficiently accurate register of members to make an allotment.

At Nottingham matters appear to have worked smoothly from the first. After three months very few misunderstandings occurred. The panel doctors and the chemists are paid every month. The panel doctors have received the full 7*d.* per month for every insured person, though the dispensing chemists have only obtained 15*s.* in the £ on their claims. But of the money received something like 15 per cent. has not been paid out, and this is due to the payments of insured persons who have not selected a medical attendant. The impression at the Insurance Committee office is that the medical men on the panel are satisfied, while that they are satisfying their patients can be taken for granted, for during nine months only one complaint had come up for investigation by the Medical Service Subcommittee. Nor can it be said that there are any panel doctors who have acquired a privileged position by filling up their list of insured persons with selected lives. The population at Nottingham is so mixed that there is no one favoured district where a list of 1000 insured persons belonging to about the same class could be found. In every district there would be some collections of good lives and some of very bad ones.

Effect of the Act on the Hospitals.

I called on one of the consulting staff of the Nottingham General Hospital and he appeared well pleased with the effect of the Act in so far as the work done at the hospitals is concerned. It had, I understood from him, so relieved the congestion at the out-patients' medical department that the staff were able to devote more time to the cases. The hospital was, he declared, "becoming a consultation station instead of a relief station." The medical men who sent their patients to the hospital, also sent a note giving their reason for so doing. The Act had greatly increased the income of those practitioners who had formerly taken contract practice, he said, and he mentioned the case of a new neighbour of his own who used to live in a very modest way and with difficulty earned £200 a year. As a panel doctor under the Act this practitioner was now, said my informant, making an income of £800, and thus could afford a better house in a better street and was obviously a more prosperous man. The hospital was also relieved of some of its work by the coöperation of the panel practitioners. Cases of accident attending at the hospital were not told to go to the panel doctor for a second and subsequent dressings as had been done at some charitable institutions. The cases were allowed to return to the hospital as a rule, but at the same time many cases of different sorts were referred to the practitioners on the panel. Though the number of medical out-patients attending the hospital had been reduced by about two-thirds, the Act has made little or no difference so far as the surgical out-patients are concerned.

The Plea against the Panel.

My next visit was to one of the practitioners who had refused to go on the panel. His action, it soon appeared, had entailed a considerable loss upon him, as he had recently taken over a practice which comprised many clubs and from these members he might have had a long list of insured persons. But he had acted deliberately, holding that contract practice was degrading to the profession and injurious to the public. The practitioners discharging contract engagements would, in his opinion, be forced by the very nature of their work to forget the dignity of their profession. Some practitioners, he said, had confessed that they had not been able for some months to devote proper

time and care to making diagnoses. They might be making more money. If in a poor street there were 100 houses, containing, say, 150 insured persons, such a street would bring to-day to the medical profession a much larger income than had ever before been received from it for medical attendance, but that the benefits either to the medical man or the patient were proportionally increased he very much doubted. The unfortunate thing, in his view, was that the contract system was increasing and reviving the faith of the public in drugs. This was just the exact opposite of what was required. The profession at the very time of the introduction of the Bill were trying to teach a better lesson, but the Government had stopped such teaching. The doctor on the panel had little time to do more than prescribe, and little more seemed needed of him. He could give something to relieve the pain, but had not time to seek out the toxic influence that caused the disease. "A pill, a lotion, the mixture as before, and—now the next" was his graphic description of such practice. He told me of a practitioner who had related to him that he had seen 100 patients during the course of the evening, and then "went to bed exhausted and heartily ashamed of himself." This sort of thing must be bad for the public and bad for the profession. At one interview a possible abuse was brought to my notice. Medicine enough for a whole week could be prescribed beforehand so as to avoid frequent visits, when the effect of this treatment would not be properly watched.

The High Proportion of Women Workers.

I now went to a partisan of the Act who has a list of 1600 insured persons. It became clear that for the practitioner whose patients belonged mainly to the working class the Act had brought about a revolution in the conditions of payment, but I learned that in Nottingham the position was not actually as favourable as that in some other towns because of the large proportion of female workers. These constituted the weak side of the health insurance scheme, both as regards the amount of work imposed on the practitioners and the drain on the insurance funds. An enormous majority of these women workers are badly paid: 10*s.* a week is the general figure, and some earn less; only a few earn as much as £1 a week. When the worker is a young woman living in her home with parents, brothers, and sisters also at work, the joint weekly income of the family may amount to £3 or £4. If the mother is not an employed person, but is a good housekeeper and can remain at home to superintend regularly the spending of this money wisely and economically, the family will be well fed and clothed. But this is rarely the case, and a properly cooked dinner is not often forthcoming in such households. It is deplorable, from the public health point of view, that so many married women are all day working in the mills instead of attending to their home duties. The little leisure these women can enjoy has to be devoted almost wholly to house cleaning, and this is much neglected during the week in too many cases. As there is rarely time to cook food properly, cheap "snacks" are bought out of doors, eaten anyhow and anywhere. Thus these workers are not properly fed, and a physical breakdown is too often the consequence. There are also a large number of women workers who have no homes of their own. They are therefore obliged to board in small cottages where they generally pay 7*s.* 6*d.* a week for their bed and board. Of course, they cannot expect much for so small a sum, and yet in too many cases the payment of this money only leaves them 2*s.* 6*d.* a week for clothes and all other requirements. The pleasures of life are sadly to seek in these women's existence. To complicate matters further, there are many more women than men at Nottingham—more than the general figures of the English and Welsh populations warrant. The Census of 1911 sets forth that for every 100 males there are 115·9 females in Nottingham. In 1891 it was 100 males to 120 females. Then the proportion went down to 100 males to 114 females in 1901; but now the number of females is again on the increase. The ratio of males to females in England and Wales is at the present time about 100 to 106·8. In Nottingham city there are now 121,604 males and 140,959 females. Further—and this bears directly on the subject—the women who make up this excess are all industrially employed, and are therefore insurable. From the clerk of the Insurance Committee I endeavoured to ascertain what was the proportion of females among the insured persons. No such estimate has yet been made, and it will take a very long time to go through and classify the 95,000 insured persons. In the absence of any precise figure to go upon, and judging very roughly, it was thought that at Nottingham about 40 per cent. of the insured persons were females, but I obtained evidence elsewhere, which I will ultimately submit, showing that the proportion of insured women is higher.

The panel practitioner who brought the question of the large female population of Nottingham to my attention assured me that he attended three women patients for one man. This does not mean that his list of 1600 insured persons consisted of 1200 women and 400 men. Doubtless the proportion of men was much more than a quarter of the whole, but it was the women who fell ill and who were constantly coming for advice. He did not suggest malingering, and even went so far as to say he did not believe that one of these women workers enjoyed absolutely good health; they were always more or less ill, though not from such forms of acute disease as would prevent them from working. They suffered from anæmia, constipation, debility, bad teeth, and dyspepsia. They could still work, and he did not find that they were particularly anxious to be placed on the sick list; they were rarely confined to their bed.

A Panel Practitioner's Routine.
